LONDON: FRIDAY, JULY 2, 1869.

THE FRENCH ATLANTIC CABLE.

THE operations in connection with this great enterprise are now in their most interesting phase, and so far as the work has been carried on, it is due to our readers that some description of these operations should be given, in order to continue the history from the point we left off at in a recent number. The movements of the "Great Eastern" have daily been chronicled since she left Sheerness and arrived off Brest, on the 21st, after a comfortable passage from Portland, which place, having taken on board the necessary amount of coal and all her passengers, she left on the morning of the 19th. Prior to her leaving Portland, accompanied by the "Scanderia," the "Chiltern" had arrived at Brest, and on the 17th had successfully laid from the shore 5½ miles of the heavy shore cable. The landing place was at Minou Creek, near Brest, where the cable end was laid in a deep trench to the small cable house. After paying out the length, which occupied but a short time, the end was let go with a buoy attached to it, ready for the "Great Eastern" on her arrival to splice on to.

The "Great Eastern," on her arrival on Sunday afternoon, anchored close to the buoy, which was lifted up by the "Chiltern" and the end passed on board. It having been decided to commence paying out at daylight in the morning, the splice between the shore end and the similar heavy cable on board was commenced immediately after the electrical tests proved the cable to be in good condition. The splicing of a heavy compound cable, such as this shore end, is a matter of considerable time, and occupied the whole night; by daylight, it was, however, accomplished, and lowered to the bottom; the anchor was then weighed, and the "Great Eastern" commenced her third submarine cable voyage across the Atlantic, weather fine, and everything promising success. The following tabulated statement, compiled from the telegrams received from the ship up to the latest date, will show the progress made :—

STATEMENT OF PAYING OUT.

Date. Noon.	Lat.	Long.	Distance run. Nautical miles.	Nautical miles payed out	Rate per hour.	Slack per cent.
June 22	48·30	8.55	174	—	5·5	—
" 23	—	—	294	310	5·5	5·5
" 24	48·30	13·53	377	405·7	4·0	7·6
" 25	48·34	17·06	497	542	5·7	9·0
" 26	48·37	18·57	574	635·9	3·9	10·8
" 27	48·32	22·01	697	775	5·8	11·2
" 28	48·22	25·11	823	916	6·0	11·3
" 29	48·6	27·50	920	1038	5·1	13·0

From this statement will be seen the gradual manner in which the water has deepened, a fact made perceptible by the increase in the amount of slack necessarily payed out. It will be noticed that between the 23rd and 24th the rate of paying out was much decreased; from what cause we cannot yet know, but the change which would take place about that time from the main tank to the fore tank would undoubtedly cause some delay. In the submerging of cables in deep water, this, to all on board, is the most anxious time, and is an operation requiring great skill and special attention. The difficulty is, however, reduced to its minimum by the employment of skilled hands—men who have been accustomed for years to similar work; and the principal foremen on board the "Great Eastern" are those who successfully managed these critical times in the old Atlantic cables.

All went well with the paying out until four in the morning of the 26th, when indications of a slight fault appeared, the insulation, or what is termed the "gutta-percha resistance," having fallen. The fault was of so minute a nature that it was impossible to localize it; so minute, indeed, as not to interfere in any way with the signalling, and it was wisely determined to proceed with the paying out. On the same day, in the forenoon, a second fault was found inboard and removed, the telegram stating "A fault was removed from cable inboard this forenoon." A third fault, however, appeared on the same morning, which was discovered in such time that it had only just passed out of the ship. It may be imagined how close it was when the telegram states "delayed this morning three hours cutting out a third fault close to ship." On the following day, the 27th, a most satisfactory telegram was forwarded from Sir D. Gooch :—"The 'Great Eastern.' Electrical condition perfect; I am glad to relieve you from all anxiety about the supposed fault. Weather very fine, and all well and hopeful." The original fault had evidently disappeared, and in all probability was in the ship. Since the above telegram, all has been going on well, and we trust that as telegram succeeds telegram their tenor may be precisely similar to the end of the chapter, "Electrical condition perfect."

It may not be uninteresting to show how, should a fault occur, immediate notice of the fact is given. Various plans of testing submarine cables during paying out have been tried, but all have their disadvantages. None, however, are in any way to be compared to the plan now adopted. This is the invention of Mr. Willoughby Smith, a gentleman of very great experience, the electrician engaged during the paying out of the old Atlantic cables, and who is again in charge of the electrical arrangements on board the "Great Eastern." This plan was first adopted in paying out the 1866 cable, and then in subsequent cables. It may be well to note here that the present system of working the Atlantic cables is due entirely to Mr. Willoughby Smith. In the old form of testing, the official at the shore end had to insulate the cable when any test was taken, and consequently was unaware of what was going on. In the present plan, a constant test can be kept up, with the knowledge of both ship and shore. The cable is attached at the shore end to a very high resistance through a galvanometer to earth. This resistance is so high that, on the ship keeping up a current from a large battery, the resistance is so great that a readable deflection can be obtained. A galvanometer is also inserted in the circuit on board the ship. If the current were maintained, the deflection on the two galvanometers would remain constant, and, during the paying out, these deflections would be constantly watched. If they remained constant, the cable remained in the same electrical condition; but, if they altered, they would show at once, both to ship and shore, something was wrong—to ship, by the increased deflection, that through a fault there was less resistance, and, consequently, more current flowing in to cause the increased deflection. On the shore, the effect would be different, as there being another method of escape, less current would arrive. By this means, we see how the appearance of a fault would be instantly detected.

The system of speaking or exchanging signals is very simple. By means of a condenser attached to the cable, which is charged with the same potential or opposite potential as the cable, the deflection is slightly altered in one direction or the other, and communication can be readily exchanged without interfering with the constant test. In addition, there are several arrangements for obtaining the measurement of the insulation and of the conductor, and also electrometers for measuring the potential, both on board ship and on shore, but space prevents our entering further into this question.

The strain in paying out is very small—less than one ton—although so long a length as seventeen miles will be in suspension in the deepest water, the resistance of the water itself to a cable of so light a specific gravity taking off the strain. The rate of sinking is estimated at three-quarters of a knot per hour.

The next occasion when we resume the history of this enterprise will, it is to be hoped, be on its successful completion; and as, in all probability, when this meets the eyes of our readers, more than one-half of the deep-sea cable will be submerged, we trust that our *resumé* will not take place until the whole is successfully and satisfactorily submerged.

Since the above remarks were written, an interruption to the successful paying-out of the cable has occurred. Something happened on the morning of the 30th, which necessitated the immediate cutting and buoying of the cable without any further warning being given than a simple notice of the fact. Unfortunately, the reason for doing so was not given, and we are quite in the dark as to what *contretemps* could have occurred. The place where the cable is now buoyed is under 2,000 fathoms of water, the ship, fortunately, having passed over the deepest part. No uneasiness is felt at Minou, and knowing the comparative ease and facility of repairing such cables, we must simply rest quiet with the conviction that in a few days all will be well.

The following telegrams are the latest to hand :—

THE FRENCH ATLANTIC CABLE.

The following telegrams have been received from Sir William Thomson :—

"Minou, Wednesday morning.

"Tests in Minou continue satisfactory up to present hour, 6.45, Greenwich time, Wednesday."

"Minou, June 30.

"Arrived here (Minou), from Brest, with Captain Osborn, noon. Telegram from Gooch of 9 a.m., Greenwich time, awaited him, saying they intended to cut the cable and buoy. This has probably been done, as no signals have come since then. We do not know the reason; the tests here up to 6·30 gave no cause for suspicion. Despatched 12.25, Greenwich time."

The following telegrams have been received by Reuter's Telegram Company (Limited), from Captain Sherard Osborn :—

"Minou, Brest, June 30.

"This morning, at 9 a.m., Greenwich time, 'Great Eastern' telegraphed to us :—'We are going to cut cable and buoy.' This has evidently been done, for no signals have passed since. A careful watch is being kept for a renewal of signals. The first sign of something being wrong in the electrical condition of the cable occurred early this morning, but nothing of a definite character until the above message reached us. We had a very long message at 11.34 p.m., Greenwich time, last night, from the 'Great Eastern,' at which time the signalling was reported by Mr. May to be most perfect. Despatched 12.10, Greenwich time."

"Minou, Brest, June 30.

"I see no reason for slightest alarm at what the 'Great Eastern' is doing. It was evident from the resistance of G. P., reported last night, that the slight fault of 25th was improving. Mr. May agrees with me in thinking they have buoyed in shoal water, and are returning to remove the fault. Delay is the only inconvenience."

NITRO-GLYCERINE AGAIN.

IT is now some time since we heard anything about this fearfully dangerous compound, and we thought that the warnings which have been given in the shape of fatal explosions—both at home and abroad—had led to the abandonment of its use in this country, and the substitution of the comparatively safe and equally efficient material—dynamite. It is not so, however, as a terrible explosion at Cwymglo, at the foot of Snowdon, on Wednesday afternoon, testifies. From various reports which have reached us, we gather that on Tuesday, a vessel, laden with nitro-glycerine, arrived at Carnarvon Bar, the cargo being conveyed in boats to Carnarvon Pier. Next day, five cartloads were dispatched, two for Assheton Smith's Llanberis Quarries, and three for Lord Penrhyn's Bethesda Quarries. When the former two were near Cwymglo, the nitro-glycerine exploded, blowing the horses and three men to atoms. The village, which is nearly a quarter of a mile off, was greatly injured, roofs and windows blown off, and, at the spot where the carts were, two round holes six feet deep and seven feet diameter were made; the railway station, forty yards off, was blown to pieces. The whole valley at the foot of Snowdon and two large lakes suffered a severe shock, the damage done all round the valley being very great. The shock was felt at Bangor, which is about nine miles from the scene of the accident. There has been, of course, hardly time for details yet, but up to the time of our going to press it had been ascertained that four deaths had resulted from the explosion, and that twelve persons were severely and seven slightly injured. An investigation into the cause of the explosion was opened yesterday and adjourned. We shall have more to say on this matter in our next.

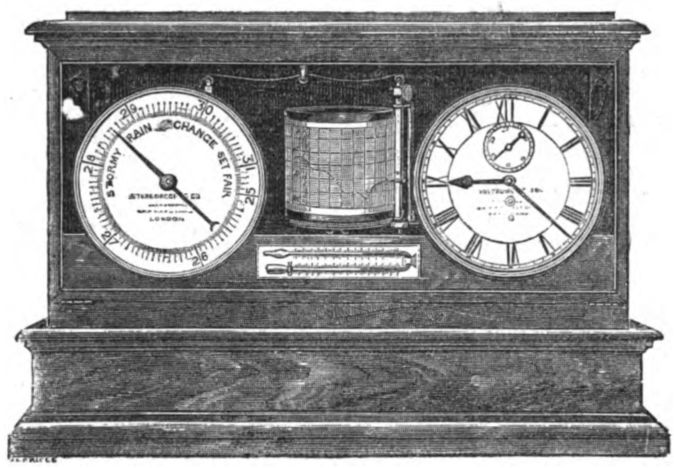
STEAM BOILER INSURANCE IN AMERICA.

HOWEVER unfortunate we in England may be in the matter of steam boiler explosions, no one can fail to have observed that our friends in the United States are still more so. The annual loss of life and property there from this cause must appear very large, even to the casual observer, whilst to those whose attention is frequently drawn to the subject, the results are really startling. It will be sufficient for the present purpose to allude to the record for the past two years, as it found its way into the papers. Such a record is of course a very incomplete summary of the number of lives lost, and the amount of property destroyed by boiler explosions in the time specified. Many explosions of a more or less serious nature are never reported by any newspaper, or, if reported, fail to meet the eyes of those interested in preserving an account of them. Incomplete, however, as it is, when we note the fact that, during two years, upwards of 800 lives have been lost in America by boiler explosions, and an immense amount of valuable property destroyed, ranging—in the various instances where any estimate was given—from 500 to 50,000 dollars, it demonstrates very conclusively the need of such a system of boiler insurance and inspection in that country as we have in our own. This necessity has been recognized—somewhat tardily, perhaps—by the Americans, who took a leaf out of our book, and in 1866 started "The Hartford (Conn.) Steam Boiler Inspection and Insurance Company," about which Association we have to say a few words. We are induced to do this from the fact that our journal finds favour in many parts of the States, where our persistent advocacy of boiler inspection is well known, and where the advantages of the system are admitted. If, then, the correctness of the principle be allowed, and if we point out to those who may not be aware of it, that American steam users have the same opportunities of making themselves safe as we in England have, there remains no excuse if they do not avail themselves of the means offered.

The Hartford Association is the pioneer company of the United States, and from particulars recently forwarded by a correspondent, we find that during the two years and a-half it has been in operation, it has extended its business by a system of well-appointed agencies over a great part of the country. Many of the largest manufacturers hold its policies, and its rapidly increasing business attests the value of its work. Its business is confined to no particular form of boiler, nor to any special class of manufacturers. It embraces ironworks, mines, cotton and woollen mills, saw mills, locomotives, steamboats and steam tugs, and, in short, all establishments where steam power is used. All boilers under its care are carefully inspected internally and externally by competent practical men four times a year. Steam gauges are tested, safety valves properly adjusted and weighted, boiler connections carefully examined, and information given relative to setting and management. The end and aim of all this, be it remembered, is economy in the use of fuel and safety to life and property. As a matter of course, the work of the company has brought to light many and dangerous defects; and there can be little or no doubt that disastrous explosions have been prevented. We know that where boilers are left unexamined for months and years together, incrustation, internal and external corrosion, burned plates and blisters, shorten their working age, and render them positively dangerous. The usual mode of inspection, applying the hydraulic test, takes no cognizance of these defects, and does but little towards insuring safety. The policy of insurance which the company issues, covers damage to boilers, buildings, stock and machinery, arising from explosions, and is a guarantee that the inspection has been thoroughly effected. It stands to reason that self-interest would cause the work to be properly done, inasmuch as the party making it has a pecuniary interest in its issue.

The company imposes no arbitrary conditions; it is interested in no patented appliances, but on receipt of the proposal for insurance, together with the inspector's report, the boilers are classified and accepted at a proper rate per cent., unless they are found on inspection absolutely unsafe, in which case the applicant is furnished with a written statement of their condition. Information relative to the management of steam boilers, monthly reports of the inspectors of the company, a list of explosions, so far as they can be obtained, for each month, and other valuable information, is disseminated amongst the policy-holders by means of a monthly paper called "The Locomotive." From what we have advanced, it will be seen that the Hartford Association is conducted upon equitable principles. The present remarks are penned with the view of promoting the interests of those steam users who are indifferent to them themselves, and of increasing public safety. We, therefore, trust that they may lead those who may read them, and who have hitherto held back, either from ignorance or obstinacy, to avail themselves of the manifest advantages of inspection and insurance. It is an old and oft reiterated opinion of ours, that it is due to the State that every man should adopt every precaution in his power to protect the life and property of his fellow subjects. A persistent disregard of this principle is a flagrant violation of the moral law which the State will not always permit with impunity to the offender.

SELF-REGISTERING ANEROID.



SELF-RECORDING ANEROID.

THOSE who have been in the habit of watching the barometer from day to day, and of recording its indications at stated hours, know that between the intervals of making the record, fluctuations in the index take place, which, if recorded, would furnish valuable data regarding the atmospheric pressure, important alike for immediate use and future investigations. Isolated observations are insufficient for many purposes. It is desirable to know also whether the pressure is increasing or decreasing, and the rate at which change is taking place. The hourly self-recording aneroid barometer is designed to supply this information, and the manner in which it does so will be best understood by a consideration of the construction of the instrument. It consists, in the first place, of a large and powerful aneroid barometer, with 8-inch dial, which, although the same in principle as those in general use, is specially constructed for this instrument, being furnished with a vacuum chamber of much larger area, thus securing increased sensibility, besides insuring the necessary amount of mechanical force to work the pencil connected with the hourly self-recording portion of the instrument. This arrangement consists simply of a light wheel, about 2in. in diameter, fixed on the centre arbor, to which is attached a length of light chain such as works round the fuzee of an ordinary watch. This chain is carried along the top of the instrument, over guide pulleys, until it reaches the pencil carrier which works on the guide rod. The pencil falls by its own weight, and is raised by an increase in the pressure of the atmosphere. This instrument was exhibited at the last meeting of the Meteorological Society by Mr. James Martin, of the London Stereoscopic Company, Regent-street.

We have examined one of these instruments (which is represented in the annexed engraving), and have also inspected a record made by it. A specimen vacuum chamber and wheel for winding the chain were also submitted to us. All the parts show evidence of sound workmanship. An eight-day clock, with 8-inch dial of special construction, having a pendulum 10in. in length, beating half seconds, furnishes the means of making an hourly record. Between the clock and the barometer revolves a vertical cylinder 4in. in diameter, having a paper attached to it, and near to this paper is fixed the guide rod supporting the pencil, which, by simple mechanism connected with the clock, marks its own position at every hour. The paper, besides being ruled horizontally into inches and tenths, to correspond with the barometer scale, is divided vertically into seven principal and seven minor divisions, indicated by darker and lighter lines. The light lines represent the noon, and the darker lines the midnight, of each twenty-four hours; the paper thus lasts one week. By these means, a black dotted curved line is produced, showing the height of the barometer, whether it is falling or rising, for how long it has been doing so, and at what rate the change is taking place—whether at the rate of 1-10th per hour, or 1-10th in twenty-four hours—facts which could only be obtained by very frequent and regular observations from an ordinary barometer, but which are nevertheless essential to a reliable "weather forecast," to say nothing of the ulterior uses to which these records may be applied in meteorological investigations.

There are two conditions upon which the scientific value of this instrument will depend, namely, the goodness of the clock and the accuracy with which the aneroid is compensated for temperature, and correctly graduated to allow for the effect upon the index, due to the work to be performed in moving the additional wheel, chain, and marker. It may be found advisable to diminish the length of chain by placing the marking mechanism by the side of the aneroid. There ought to be no difficulty with respect to the clock, which can easily be made to keep time within three or four minutes per week—a sufficient degree of accuracy for the purpose. With due care, the aneroid could be brought to sufficient perfection to show on the record the barometric pressure at the standard temperature —32deg. Fah.—correctly to within 0·01 or 0·02 of an inch. The degree of accuracy, however, can only be ascertained by proper comparisons with a standard barometer. It would be desirable to determine whether the error of indication is constant, not only throughout the scale but both when the marker is rising and when it is falling. These points we indicate for the guidance of the manufacturers as well as of observers who may use the instrument. The former should direct their attention to them because the demand for the instrument will, doubtless, depend upon the degree of accuracy which can be imparted to its records. We have had no means of testing its accuracy ourselves, but shall be glad to give publicity to any authentic verifications which may reach us.

MANUFACTURE OF CAPS AND CARTRIDGES.

No. VIII.

THE cartridge cases being completed and ready to be filled, are despatched to have this final operation accomplished. The gunpowder is supplied by the war authorities, who forward it to the premises in casks, containing about a couple of hundredweights. These casks are carefully stored in a powder magazine, which is isolated from all neighbouring buildings, and surrounded by four massive walls, constructed of earth and stone. A small tramway is laid down for the transport of the powder to and from those parts of the establishment where it is needed. The building in which the filling of the case is conducted is also separated from its neighbours, and divided into a number of interior compartments. The powder is conveyed to one end of an apartment containing a weighing machine, in which the cask is placed, having been previously opened with a bronze chisel. This instrument is employed instead of the ordinary one of iron, for fear of a spark being generated by the violent contact of the latter implement with a nail or other hard foreign substance that might by accident be present. The weighing machine is furnished with a leather funnel, which conducts the powder into large copper jugs. Similarly to all the other workshops where the manipulation of the powder is carried on, the floor of this apartment is covered with oilcloth, in order to facilitate the complete removal of what escapes in the various operations it undergoes, and all projections of the walls are papered to prevent it adhering to them. Although there is not much danger with this as with the fulminating powder, yet it is wisely considered that too much precaution cannot be taken to obviate the chance of accident. In order to guard against the accumulation of too large a quantity of powder in the interior of the workshops, a number of hoppers are ranged in a corridor running parallel to the wall of the workshops. These hoppers are protected by shields of wrought iron, which are pierced with holes communicating with the interior of the workshops. It is into these hoppers that the foreman empties the copper jugs containing a charge of about nine pounds. The principle of "division of labour," which is carried into universal practice throughout the whole establishment, does not permit the same workman to begin and finish a job. Thus, the women who fill the cartridges never leave their place. The empty ones are supplied to them and the full ones taken away by a special provision, with which they have nothing to do. There is one entire apartment devoted solely to placing the empty cartridge cases into frames pierced with holes to receive them. These frames, resembling a hand in shape, and holding half a hundred cartridges each, are subsequently transported by a small lorry into the charging rooms.

In each of these rooms there are two tables ranged along the sides, behind which women are seated, and another in the middle, at which a woman stands up. Upon this central table the frames, with the empty cartridge cases, are deposited, the opening being upwards. The woman seizes each of them by the smaller end—technically speaking, by the wrist—and pushes them through the hole in the wall communicating with the hopper, at the same time pressing upon a piece of mechanism similar to that which distributes the fulminating powder in the caps, as already described. After withdrawing the frame with the charged cases, she passes them to the other tables, where the wad and the ball are introduced, and they are ultimately conveyed away from the room by the same means by which they were transported thither.

Before continuing the description of filling and finishing the cartridges, it is necessary that some notice be taken of the balls and the manner in which they are cast. We have long since renounced the primitive spherical ball, and engineers, both civil and military, have taxed their inventive powers to the utmost to improve these warlike missiles. For a long time, the solid conically-cylindrical grooved ball was the favourite projectile, but under certain circumstances it has been found that it is sufficient to make the conical part only solid, provided the cylindrical portion was strong enough to take the rifling. It was, therefore, proposed, in the case of converted guns, to introduce into the hollow of the ball a small cylindrical core or cut plug, out of a roll of compressed paper. The balls in the cartridges intended for converted guns are of lead, solid in the conical part and hollow in the cylindrical, for the purpose of receiving the core. This latter is of paper, and cut by means of circular knives. The section gives a cylinder, which is placed under the action of a machine furnished with a punch and die, and is reduced to the exact form of the cavity it is destined to fill. The balls are cast in a mould, closely resembling that used for casting type in. A cistern or copper, supported by brick foundations, contains the lead in a state of fusion, around which the workmen are gathered. They ladle out the molten metal into the moulds, and the balls are subsequently drawn out in bunches, being held together by a strip of lead. They are then plunged into a melted mixture of fat and wax, in order to cover them with a coating of grease sufficiently compact, when cooled and coagulated between the grooves, to preserve the edges. The next step consists in cutting off the balls one by one from the bunches, and in handing them over to a gang of boys, who place the core in the cavity and transfer them to another gang, who fix it by a blow from a machine, which, at the same time, compresses the metal, shortens the ball by increasing its lateral dimensions, and increases the density of the solid conical part. Previous to these operations, all the balls that are badly and imperfectly cast are rejected; so also are those which fail in the stamping and forging of the core, and there is a considerable percentage when both operations are taken into account. The rejected balls are thrown into a furnace, where the core or plug is consumed and the metal run into ingots, ready for future use. All the balls that fulfil the required conditions of size and shape are despatched to the filling premises described above, where they are inserted in the cartridges.

It must not be supposed that the manufacture is quite completed yet. The cartridges have still to be tested, gauged, and the ball securely fixed, so as to avoid all chance of its getting loose from the case containing it. This last operation is accomplished in a very ingenious manner. The cartridge is placed with the copper end downwards in a socket, and quickly submitted to the grip of a description of pincers with four arms, the joining of which by an encircling ring produces a circle. Between these arms the ball is placed. A blow from a lever causes the ring to descend to close the arms of the pincers, and make an indented circle round the ball, while at the same moment it compresses the paper and the tinsel of the cartridge case in the first groove of the ball, thus firmly fixing it to the case. In fig. 1 is represented a

FIG. 1.

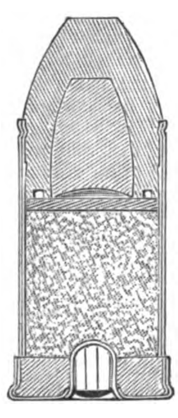


FIG. 2.

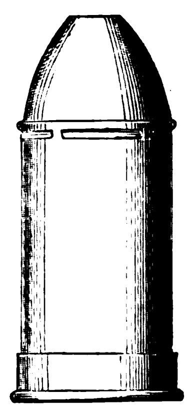

longitudinal section of the finished cartridge, showing the ball and the core; and in fig. 2 an elevation of the same, where the junction between the ball and the case is distinctly visible. The cartridge is now completed.

They are made up in packets of six, and stowed in cases well packed with hemp. A permanent commission is deputed to take at hazard every day five hundred of these cartridges and fire them off; and if more than one in a hundred miss fire, it is sufficient to cause the rejection of the supply tendered. There is never a missfire oftener than one in a thousand, although, in the converted gun, the point driven by the hammer only strikes the cartridge obliquely. It is the little anvil that insures a freedom from missfires, for it always opposes a hard surface to the point striking upon the priming, at whatever angle the blow may be made.

THE ROYAL INSTITUTION.

THE lecture by Mr. H. C. Fleeming Jenkin, F.R.S., on Submarine Cables, was delivered on May 21, and has already been published by us. At the close of the lecture, Messrs. O. and F. H. Varley, telegraph apparatus manufacturers, exhibited in the library some interesting specimens of corals and oysters, gathered from the Malta and Cagliari cable, during the picking up from depths varying from 60 to 300 fathoms. They also exhibited some newly invented apparatus now in use on board the "Great Eastern," for the testing of the French Atlantic cable, including a double slide and subdivider, the joint invention of Sir William Thomson, Mr. Fleeming Jenkin, and Mr. Cromwell F. Varley. The double slide comprises a series of 101 coils, the resistance of each being adjusted to equal 1,000 British Association units or Ohms. The second slide or subdivider comprises 101 coils of 20 Ohms each. The coils of the double slide and the subdivider are connected to separate terminal plates, by which contact is made through a strong spring attached to a carriage, made to travel on two parallel rails. The position of the carriage read off on a divided scale determines the value of the potential. The subdivider is a looped circuit, and subdivides the reading of the double slide 100 times. When the double slide and subdivider are joined together, the resistance of the double slide is reduced from 101,000 to 100,000 Ohms, 1-100th of the current flowing through the subdivider; and as this has 100 divisions, a reading to five places of figures to be obtained, this transferred to a table of reciprocals, gives the value of the potential.

Another piece of apparatus for testing the French Atlantic cable was a new electric balance, the invention of Mr. C. F. Varley, C.E. This balance has a slide capable of multiplying from 1-1,000,000th to 1,000,000 times, without altering the resistance in circuit, or affecting the actual potential when obtaining a reading. It can with great facility be made to measure a very small amount of resistance—for instance, that of the conductor of a cable—and then without any change of connections in the balance, give the value of a very large resistance; for example, that of the insulator of the cable, which frequently in good cables amounts to from 300 to 8,000 millions of British Association units. This instrument is capable of giving the most extended range for electrical determinations, and the results are read off direct without any further arithmetical process than one of simple subtraction.

On Saturday, May 22, Professor Seeley gave another lecture at the Royal Institution on "Roman History"; and on Tuesday, May 25, Professor Grant delivered his eighth lecture on "Stellar Astronomy," in which he called special attention to the nebulæ. On Thursday, May 27, Professor Tyndall delivered his eighth lecture upon "Light." In it, he described the different methods of polarizing light, and closed by examining the light transmitted by Iceland spar.

NOTICES OF BOOKS.

THE name of Mr. Thomas Box will be familiar to many of our readers as the author of two very useful treatises—one on hydraulics and the other on heat. He has now given students and beginners another equally useful work on mill gearing,* which treats of the subject generally, including wheels, shafts, riggers, &c. Here the student will find himself made easily familiar with all the puzzling details of the forms, proportions, powers, &c., of wheels, as well as shafting, with its bearings, couplings, cranks, and strains. Riggers and pulleys, and the various methods of keying, are also described, the whole being illustrated by eight clearly drawn lithographed plates. Like Mr. Box's other treatises, the one under notice possesses the recommendation of being clearly and simply written, whilst, at the same time, it is thoroughly practical.

An attempt to solve the old question, "What is matter?"† has been made by an Inner Templar, in a volume full of theory and speculation, but still, doubtless, interesting to those who pursue the study of physical science to the utmost limits of conception. Our author admits the many unsuccessful attempts which have been made in all ages by philosophers to solve the problem of the world's existence. He has read deeply upon the subject, absorbing into his mind the heterogeneous ideas of every eminent man from Thales to Kant, and then, as he tells us, without making a single experiment, and with only a ruler and a pair of compasses, he has constructed "an edifice which, harmonizing in all its parts, will defy all the insidious workings of time, with all the power that either talent can produce or ingenuity afford." For the details of construction of this "harmonious edifice" we refer our readers to the work itself, merely observing that, as a rule, we find true genius less boastful and defiant than the genius of the Inner Temple.

We have received two books from Messrs. Atchley and Co., the architectural publishers. The first is a volume of carefully prepared illustrations of Kettering Church, and which have just been revised by the author. The plates are twenty in number, and comprise plans, elevations, sections, and details of this interesting specimen of ecclesiastical architecture. They are preceded by descriptive matter and some historical remarks. This church is one of a class peculiar to the district in which it is situated. It has a lofty spire, whilst the body is comparatively stunted, although on examining the interior views of the edifice its capacious character is at once apparent. There are some points of detail about the church well worthy the notice of the professional architect, whilst, at the same time, there are others which are to be avoided.

The other book to which we have referred is "The Architect's Guide" (Atchley and Co.), which is the production of Mr. W. Davis Haskoll, Mr. R. W. Billings, Mr. F. Rogers, and Mr. P. Thompson; the late Mr. George Rennie having contributed the results of numerous experiments. It is a book full of information relating to building, surveying, and similar matters, the value of which is guaranteed by the names of the authors. It will be found a most useful office or pocket companion to engineers, architects, surveyors, builders, and all who are connected in the work of construction. It contains some practical wrinkles well worth knowing.

"The Ruthven Hydraulic Propeller *v.* the Screw and Paddle" is the title of a pamphlet (Haddon and Co., 29, Budge-row), in which the former is proved to have attained a great superiority over the latter. Mr. Ruthven's system of hydraulic propulsion has been fully described and illustrated by us in a previous volume, and its performances have been recorded. The proof of superiority over the screw lies in the fact that the "Waterwitch," at the Maplin Sands measured mile, attained a speed of 9·9 knots with 834-horse power, whilst the "Viper" and the "Vixen"—double screws—competing vessels, attained a speed of only 9·1 and 9·2 knots with 707 and 751-horse power respectively. For the interesting details of these and numerous other trials we refer our readers to the pamphlet under notice.

An epitome of the progress of the trade in coal to London since the year 1775, has just been published by Mr. J. R. Scott, 32, Coal Exchange, London. It contains a great deal of information which cannot be otherwise than acceptable to those engaged in the coal trade. It is accompanied by a map of the coal duty district, and includes returns of imports, averages of prices, yearly summaries, yearly tonnage of vessels, &c. This useful little book is to be re-issued, with additions, in January every year, so that our coal merchants may annually post themselves in the statistics of the trade at an early period. As an example of the information conveyed, we extract the following table of the quantity of coal which entered London during the last ten years, which also shows the progress made by the railways:—

Year.	By sea. Tons.	By railway. Tons.	Price per ton. s. d.
1858	3,266,446	1,190,521	18 5
1859	3,299,170	1,191,169	18 4
1860	3,573,377	1,477,546	20 1
1861	3,567,002	1,642,502	19 6
1862	3,442,402	1,513,296	17 7
1863	3,335,174	1,775,487	18 2
1864	3,166,703	2,342,440	20 1
1865	3,161,683	2,733,056	20 2
1866	3,033,193	2,969,896	20 1
1867	3,016,416	3,295,652	20 8
1868	2,931,230	2,979,333	18 7

The Health Committee of Liverpool have issued the report of their engineer, Mr. James Newlands, which contains a vast array of facts and figures of special interest to the inhabitants of the borough. Besides this, however, there are many things well worthy the attention of boards in other cities and towns. Tramways, sewerage matters, steam road-rolling, &c., are items to the point. The report is printed by Tinling and Co., 44, Cable-street, Liverpool.

The principles of book-keeping are popularly explained, and the theory of double entry analyzed, in a small volume just published by Lockwood and Co., 7, Stationers' Hall-court. It is written by an experienced book-keeper, late of H.M. Civil Service, and will be found useful by young men commencing business, candidates for civil service appointments, and students generally. The author lays down the principles of book-keeping so simply, and illustrates them by such clear examples, that he cannot fail to be understood and appreciated.

Mr. Henry Laxton has compiled a most useful series of tables for workmen's wages, published by Letts and Co., Royal Exchange. The tables are easy of reference, and contain upwards of 7,000 calculations for the use of mechanics and others. Rates of wages are shown at per year, half-year, quarter, calendar month, lunar month, week, day, and hour. From the same publishers we have some samples of sectional drawing paper which they have lately introduced, and which will prove very useful to engineers, architects, surveyors, &c. They do not claim for them any superior merit or mathematical exactness, but put them forward rather as a cheap paper, on which rough plans can be drawn to scale, and coloured without the ruled lines showing objectionably through the work. Messrs. Letts have also issued a book of labels, useful for shelves, books, flowers, &c. They are gummed on the back, and are torn

* "A Practical Treatise on Mill Gearing." By THOMAS BOX. London: E. and F. N. SPON, 48, Charing Cross. 1869.

† "What is Matter?" By an INNER TEMPLAR. London: WYMAN and SONS, 74, Great Queen-street, Lincoln's Inn-fields. 1869.

out of the book and from each other in the same way that checks are, being perforated on the postage stamp principle.

Mr. R. Brandon has issued a second edition of his pamplet on cheap railway fares (Bell and Daldy, York-street, Covent Garden). Mr. Brandon shows that fares for any distance of 1s. first class, 6d. second class, and 3d. third class (existing fares below these rates remaining as at present) would be remunerative to the shareholders, beneficial to the public, and profitable to the State.

Intending emigrants to Canada should read a pamphlet describing the soil, climate, resources, institutions, &c., of the province of Ontario. It is issued by the Government of Ontario, and we believe it is to be obtained from Mr. W. Dixon, 11, Adam-street, Adelphi, London.

The "British Workman," the "Band of Hope Review," and similar publications, come to hand every month from Messrs. Partridge and Co., 9, Paternoster-row. We cannot too warmly commend them to the notice of those who are interested in elevating the moral standard of our working classes. They contain matter of interest to all classes. Take, for instance, the last number of the "British Workman," which contains a beautiful page engraving of our sea birds, by Harrison Weir, and an interesting notice of them. The bill recently introduced into Parliament for the preservation of sea birds forms the text of some excellent remarks, in the course of which we read that the diminution of the birds on our coasts is something astonishing to those who can remember their numbers a few years since, before the multiplication of railroads and steamboats brought crowds of pleasure seekers to the seaside. Around the South Stack Lighthouse, near Holyhead, the birds are protected on account of their services to sailors; but on Puffin Island, also on the Anglesey coast, the birds which gave their name to the rock are almost extinct. On the Great Orme's Head sea-fowls formerly abounded in such numbers that guns were fired from steamboats when passing the promontory, that those on board might see them rise in crowds when startled by the noise; now they are few indeed. On the Yorkshire coast they bear the name of "Flamborough Pilots." Were the fashion of decorating hats with the feathers of our native birds to become obsolete, one great cause of their devastation would cease to operate. Some years ago, the beautiful kingfisher, the gayest and most tropical-looking of our feathered compatriots, was threatened with extinction; and now the denizens of our cliffs are in danger. An order was lately given to the keeper of Ailsa Crag for 1,400 kittiwakes. If this demand is a sample of what occurs in other places, the wonder is that any birds are left. We are glad to find that through the exertions of some gentlemen in Yorkshire, who are interested in natural history, an influential association has been formed for the protection of sea birds during the breeding season. Contributions and suggestions in aid of this good object will be thankfully received by the Rev. H. F. Barnes, incumbent of Bridlington, one of the secretaries of the Association. It is chiefly through the efforts of this Society that the Act of Parliament has been obtained for the protection of the sea birds.

We have received another copy of the "Aerostatic Magazine" for 1869, but inasmuch as we noticed that periodical in our issue for April 2 last, we need do no more here than acknowledge its receipt.

NOTES ON RECENT SCIENTIFIC DISCOVERIES, AND THEIR PRACTICAL APPLICATIONS.

TO OBTAIN OXYGEN WITHOUT EMPLOYING HEAT—TO GIVE A GOLDEN APPEARANCE TO STEEL PENS—TO BRONZE PORCELAIN, STONEWARE, &c.—NEW PROCESS FOR PRESERVING MEAT FRESH.

WE have already published one or two processes for getting oxygen without the employment of heat. They are necessarily expensive, and not applicable to industrial purposes. But small quantities of pure oxygen are sometimes required when cost is of no importance, and simplicity of manipulation everything. Böttger, who devised the process, takes equal weights of peroxide of barium and peroxide of lead, and having mixed them together, adds some very weak nitric acid. Active effervescence immediately commences, and it is found that the gas evolved is pure oxygen. It will be seen that, according to Schönbein's theory, one of the peroxides employed evolves ozone, and the other antozone, or oxygen in the positive and the negative states, and these combine as they are given off to form neutral or ordinary oxygen. This process is of more scientific than practical interest; but it may be useful perhaps when small quantities of oxygen are required for medicinal purposes.

Böttger also tells us how a golden appearance may be given to steel pens, which may not be new to all our readers, and which is so troublesome that the result could hardly pay. The pens are first coated with copper by means of a battery and the ordinary cyanide solution. Then a very thin coating of zinc is given by the use of a weak battery, and a moderately strong solution of sulphate of zinc. The pens are then scoured with chalk and water, rinsed and dried, and afterwards thrown into boiling linseed or cotton seed oil, where, in a few minutes, they assume a colour closely resembling that of gold. Böttger tells us that the colour comes at about 350deg. Fah. The pens have now to be cleansed from the oil, which every one knows how to do.

The same industrious technologist gives a simple bronzing process applicable to porcelain, stoneware, and composition picture and looking-glass frames. The articles are first done over with a thin solution of water-glass by the aid of a soft brush. Bronze powder is then dusted on, and any excess not adherent is knocked off by a few gentle taps. The article is next heated, to dry the silicate, and the bronze becomes firmly attached. Probably, in the case of porcelain, biscuit, or stoneware, some chemical union of the silicate will take place, but in other cases the water glass will only tend to make the bronze powder adhere to the surface. After the heating, the bronze may be polished or burnished with agate tools.

The meat supply is a question of so much importance to our industrial classes that we add another to the many processes for preserving fresh meat we have already communicated to our readers. This process is of French origin, and we borrow our account of it from a report to the Société d'Encouragement, of Paris. M. Gorges (who bears an appropriate name) first immerses the meat in a mixture consisting of 85 per cent. of water, and the remainder glycerine, hydrochloric acid, and bisulphite of soda. When withdrawn from this bath, the pieces (which may be from four to a hundred pounds in weight) are dusted over with powdered bisulphite of soda, and closely packed in tinned-iron cases, and soldered down. The meat, it is said, will keep fresh and juicy for any length of time, and, when the cases are opened, the joints will look as though they had been cut only a quarter of an hour before. The flavour of sulphurous acid they will certainly possess can, we are told, be easily got rid of by washing them with vinegar and water, and leaving them in the air, to which they may be safely exposed for eight and forty hours. However inventors may differ as to the means they employ, they all agree in telling us that meat prepared by their processes in South America can be sold at a profit in London or Paris for 2½d. or 3d. per lb. It is curious that no one seems to have the courage to speculate with a cargo. When it is certain that no cooked preserved meats will ever come into general use for home consumption, all these processes for keeping meats fresh deserve attention. The one we notice now does not, we confess, look very promising. We have no doubt the meat is kept sweet, but cannot help thinking that the taste of sulphurous acid will stick to it.

SCHOOL OF NAVAL ARCHITECTURE.

THE next examination for the admission of persons into the Royal School of Naval Architecture and Marine Engineering will commence, by direction of the Lords Commissioners of the Admiralty, on July 19. The pupils will be selected by competitive examination, the subjects for which, and the number of marks assigned for each, are as follows:—Pure mathematics, including arithmetic, mensuration, geometry (plain and descriptive), plane trigonometry, and the elements of the differential and integral calculus, 2,500 marks; applied mathematics, including mechanics and hydrostatics, 1,000 marks; practical shipbuilding, including "laying-off" (for shipwright candidates only), 2,500 marks; practical marine engineering (for engineer candidates only), 2,500 marks; French, 500 marks; elements of physics and chemistry, 750 marks; English grammar and composition, 750 marks; geography and history, 750 marks. The last four subjects, although counting in the competition, will not be considered obligatory. No candidate will be admitted who does not obtain at least two-thirds of the full number of marks in the two first-named subjects, and three-fifths of the full number either for practical shipbuilding or marine engineering.

THE PROPOSED CHANNEL TUNNEL.

YESTERDAY week, a committee of the promoters of the project for a submarine tunnel between Dover and a point near Cape Blanc-Nez, on the French coast, had an interview at the Board of Trade, Whitehall-gardens, with the Right Hon. John Bright, President of the Board. Lord Richard Grosvenor, M.P., chairman of the committee of promoters, introduced the deputation, which included Admiral Elliott, Messrs. William Hawes, Stephenson Clarke, John Hawkshaw, C.E., James Brunlees, C.E., William Lowe, C.E., Thome de Gamond, C.E., and William Bellingham, secretary. In introducing the deputation, Lord R. Grosvenor explained to Mr. Bright the steps that had been taken to promote the object. The subject had been brought under the consideration of the Emperor Napoleon and the Imperial Government of France, by whom a commission of scientific men had been appointed to examine and report. The commission had reported in favour of the scheme and its practicability. The promoters ventured to think that, in an important international work of this character, involving very large expenditure, it would not be considered unreasonable in them to look to the two Governments of England and France for a certain degree of material encouragement and support. They accordingly respectfully solicited the two Governments to guarantee each 2½ per cent. upon two millions sterling to be applied to the driving of two parallel mining headings or drift-ways from shore to shore. The French Government were waiting to see what action the English Government would take in the matter, and the object of the deputation in waiting upon Mr. Bright was to ask respectfully that Government would take the subject into consideration. Mr. Bright asked a number of questions chiefly affecting engineering points, and the practicability of the scheme. The questions were answered by the engineers and others of the deputation to the satisfaction apparently of the right hon. gentleman, who engaged to take an early opportunity of bringing the matter under the consideration of the Cabinet.

THE CRYSTAL PALACE.

THE grand musical festival and fête at the Crystal Palace, in honour of his Highness the Viceroy of Egypt, which took place last Tuesday, was unquestionably the great success of the season. It is only at the Crystal Palace with all its accessories that such a success could be achieved. The orchestra comprised about 4,000 performers, who, under the able and precise leadership of Sir M. Costa, rendered the various pieces of the programme, both instrumental and vocal, with the highest effect. The pyrotechnic fête was on a scale of unusual magnificence, and it is not too much to say that such a display was never seen elsewhere. The facilities afforded by the terraces, the fountains, and the grounds at Sydenham, are most advantageous for the development of the scenic effect obtainable by the aid of pyrotechnic art. The festival was honoured by the presence of the Viceroy, the Prince and Princess of Wales, Prince Arthur, and the Prince and Princess of Teck. The official returns show that 33,628 visitors availed themselves of an opportunity rarely offered even by the enterprising and successful managers of the Crystal Palace Company.

METHOD OF FISHING AND CATTING ANCHORS WITH ONE HOIST.

BY MR. E. S. GRIFFITHS.

Fig. 1.

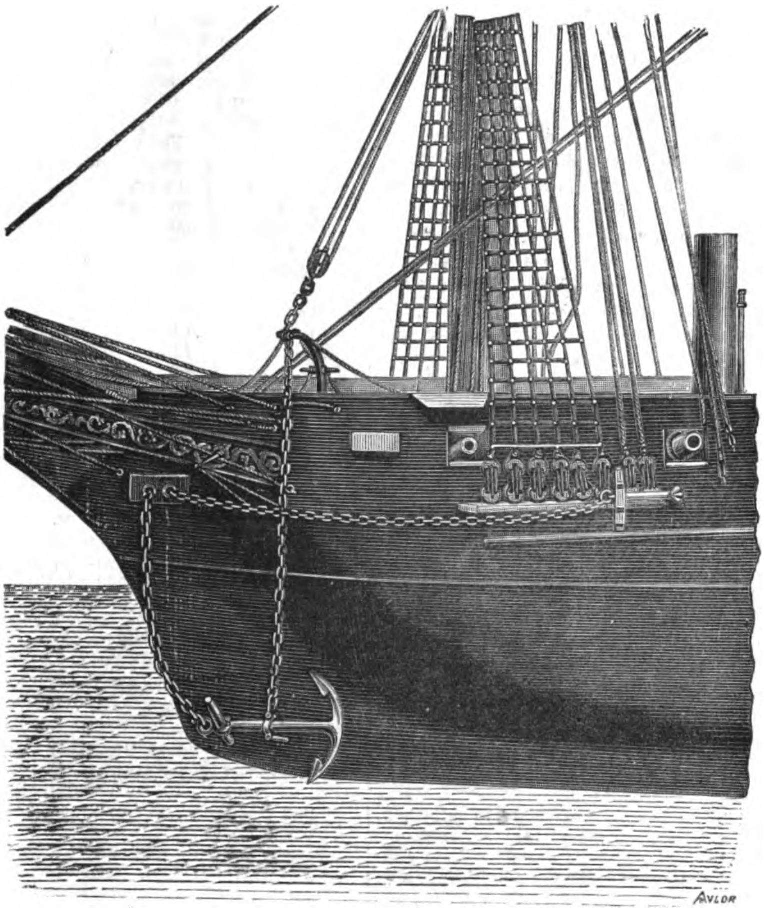

Fig. 2.

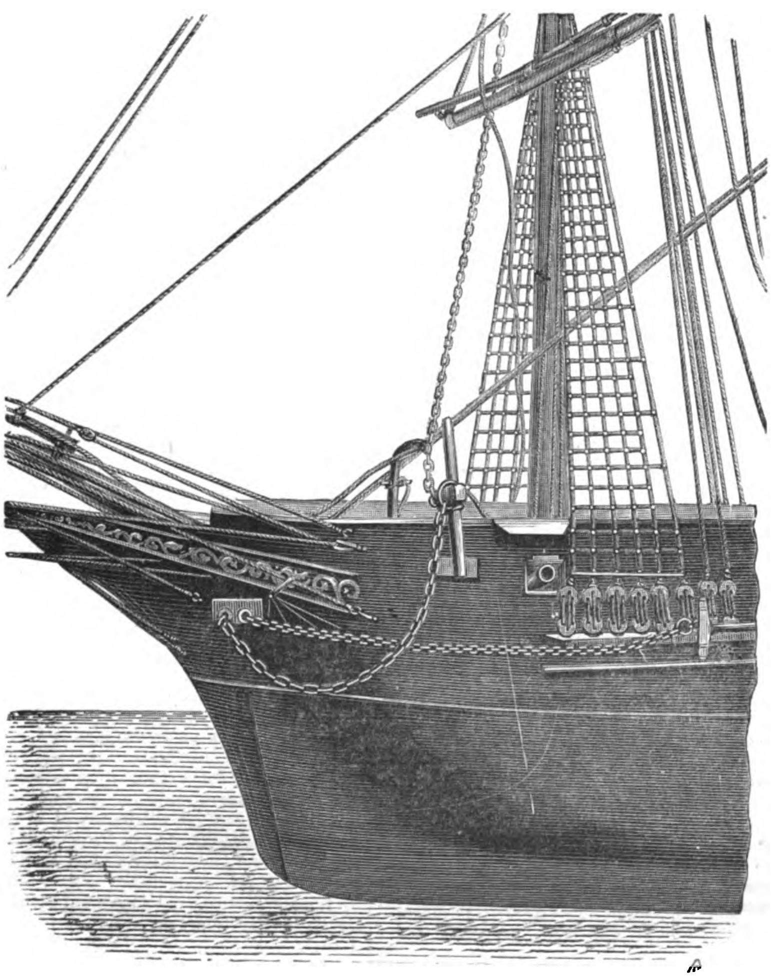

FISHING AND CATTING ANCHORS WITH ONE HOIST.

MR. E. S. GRIFFITHS, of 19, Cavour-terrace, Sheerness, has just patented the improved method of carrying anchors inboard after weighing illustrated in the accompanying engravings. Mr. Griffiths' invention is carried into effect in the following manner:—He secures to a shackle on the anchor, about the middle of the shank, one end of a pennant, the other end of which is attached by a loose shackle to the cable. When the anchor is weighed, the pennant passes through the hawse pipe with the cable. The pennant is then detached from the cable and attached to a chain passing over a block on a davit, and then led through the hawse pipe. The men then haul on the chain so as first to draw the pennant back through the hawse pipe, and then to raise the anchor up to the davit, when it can be stowed or secured inboard, the cable being slacked as required. The davit is free to turn on a vertical axis. The pennant may have a long link about the middle thereof to facilitate the lifting of the anchor if fouled.

In our engraving, we have shown Mr. Griffiths' apparatus in the several positions it occupies. Fig. 1 represents the bow of a vessel with the pennant secured to the shank of an anchor of the ordinary construction; it is secured at about the middle of the shank by means of a link or shackle. In this figure, the anchor is shown as lifted up to just below the top of the water, and, after the pennant has been roved through the eye or block of the davit, the cable being allowed to run slack to take off the strain and unnecessary pull when the pennant is lifting. Fig. 2 shows the same anchor lifted by the pennant over the gunwale and stowed inboard. It will be observed in fig. 3 that the pennant passes through the hawse hole and is in connection with the cable by means of a loose shackle, while the anchor is hanging from the bows and is ready to be cast. In some cases, the ring is fitted with a long link for attaching the pennant to.

In fig. 4 we have shown a short length of chain connecting the lower end of the shank with the cable ring; to this chain the pennant can be secured as shown, so that the anchor can be lifted in a more suitable manner for stowing. In this figure, the anchor is of the construction known as Porter's Patent. Fig. 5, which will be found on page 11, represents an anchor which has become fouled by the cable being coiled round one of the fluke arms. In accidents of this kind, Mr. Griffiths' pennant is particularly serviceable, as the anchor can be lifted by the pennant level with the gunwale of the vessel, and the fouling removed by the seamen from the deck, in addition to preventing risks to the lives of the seamen engaged. The anchor can be held and suspended by the pennant, to be let go at any moment by means of a slip stopper.

The following are amongst the advantages of Mr. Griffiths' method of fishing and catting anchors:—The anchors can be lodged on the bill board in safety, and can be carried aft or inboard with much more ease than by any of the present arrangements. As soon as the pennant comes in the hawse pipe there is no further necessity of surging the cable, as the anchor is placed on the bill board without any further trouble. There is no necessity for a man to go over the bow to hook the cat or fish, thus doing away with the hazard of human life, more particularly with a foul anchor. On a lee shore there is the advantage in the arrangement of stowing the anchor in a much quicker time, so that the vessel's weigh shall not be obstructed. In consequence of using the pennant in connection with the davit, the anchor is prevented from fouling at the fore foot, and it is brought up clear of the ship without injuring the bow. By having a long link in the middle of the pennant, the lifting of the anchor will be facilitated in the event of fouling. The anchor can, by being brought to the davit, be carried either on the bill board and stowed or be placed on deck, if required, with much less help; and the same appliance will hoist it out where required to great advantage. The pennant, with the assistance of a back line, is brought to the purchase. The anchor being stowed and the pennant passed back through the hawse pipe and connected to the cable, it is ready for use. By taking the lashings off the anchor, it is suspended by a slip stopper ready for letting go the anchor when required, and the anchor will fall clear of the bow without damaging or fouling.

For long voyages there is no necessity for a second catting, as the anchor is at once in place If the stock of the anchor becomes defective or

damaged it can be repaired, and the same appliance that brought it in can take it out to a great advantage of labour. For all coasting vessels—such as smacks, brigs, steam colliers, &c.—it can be fitted at a much less cost than is done at present. The pennant proposed can be used at the ring, shank, flue, or span, to fetch the anchor to the bow already for stowing, by the assistance of the single pennant, which would by the same purchase land the anchor inboard. These appliances may be used athwart the deck by the assistance of a fore and aft purchase. The invention can be adopted to all sized craft and any form of anchor, bringing it inboard, if required, either with or without the cathead or davit; the same can be done without either the cathead or davit, providing they were carried away by the burton or fore tackle.

H.M.S. "INCONSTANT."

THIS fine screw frigate made her official trial trip on Wednesday last, at the measured mile in Stokes Bay. The trial was commenced at full boiler power, and two runs had been made over the mile, when it was found that the wheel ropes of the rudder had became slackened. In consequence of this, she had to be taken off the mile in order that the ropes might be adjusted. This mishap placed the machinery at a disadvantage, and as the bearings had become heated, and considerable water had been made, the trial was brought to a somewhat abrupt termination. Only five out of six runs at full boiler power were made, leaving the runs at half-boiler power and the circles uncompleted. The "Inconstant" was intended to run at the rate of fifteen knots per hour, and under the above adverse circumstances she attained a mean speed of over sixteen knots. The following is the result of the five runs made at full boiler power:—

		knots per hour.
1. 3min. 42sec.,	being at the rate of	16·216
2. 3min. 51sec.	" "	15·584
3. 3min. 28sec.	" "	17·308
4. 4min. 6sec.	" "	14·634
5. 3min. 27sec.	" "	17·391

The engines of the "Inconstant," which were manufactured by Messrs. Penn and Son, are of 1,000-horse power nominal, with 112-inch cylinders, 38-inch trunk, 104½in. effective diameter, and 4ft. stroke. She is fitted with a two-bladed Griffiths' screw propeller of 23ft. diameter, and an average pitch of 24ft. The machinery is similar to that supplied to the "Bellerophon." The draught of water forward on the recent trial was 20ft. 9in., and aft 24ft. 9in. There was considerable vibration, especially aft, but not nearly so much as on the occasion of her preliminary trial.

PATENT LAW REFORM.

ON the evening of yesterday week a conference of members and friends of the Inventors' Institute was held at the office of the institute, 4, St. Martin's-place, Lord R. Grosvenor, M.P., in the chair. The object of the conference was to consider the action to be taken in opposition to the measures now in progress for the abolition of patent rights. The chairman opened the discussion by explaining the object for which the institute was formed, and which now numbered 700 members. They held the opinion, after mature deliberation, that it was not desirable to abolish the existing patent laws, though they were willing to admit all useful and appropriate amendments. It was in the interest both of the public and the inventor that the existing laws should remain in preference to a system of remuneration by the State, and therefore they had resolved to oppose the plan for the proposed abolition of patent rights. The discussion was continued by Messrs. Imrie, Dircks, Williams, Richardson, Hemans, Potter, Connolly, and others, at the conclusion of which four resolutions were submitted to the conference, affirming that the inventor was entitled to remuneration for his labour, expenditure, and skill as much as the author or artist to copyright for his book or work of art; that capital would not be embarked in promoting inventions unless profitable return for such capital is assured by the operation of law, such as is done by the existing patent law; that a good system of patent law tends to foster the trade and industry of the country and to maintain its industrial position against the active pressure of foreign competition; that working men are especially interested in supporting the present law, by which they can not only safely exhibit their inventions in public, but reap the fruits of improved education and increased application of inventions. The above resolutions were carried unanimously.

METHOD OF FISHING AND CATTING ANCHORS WITH ONE HOIST.

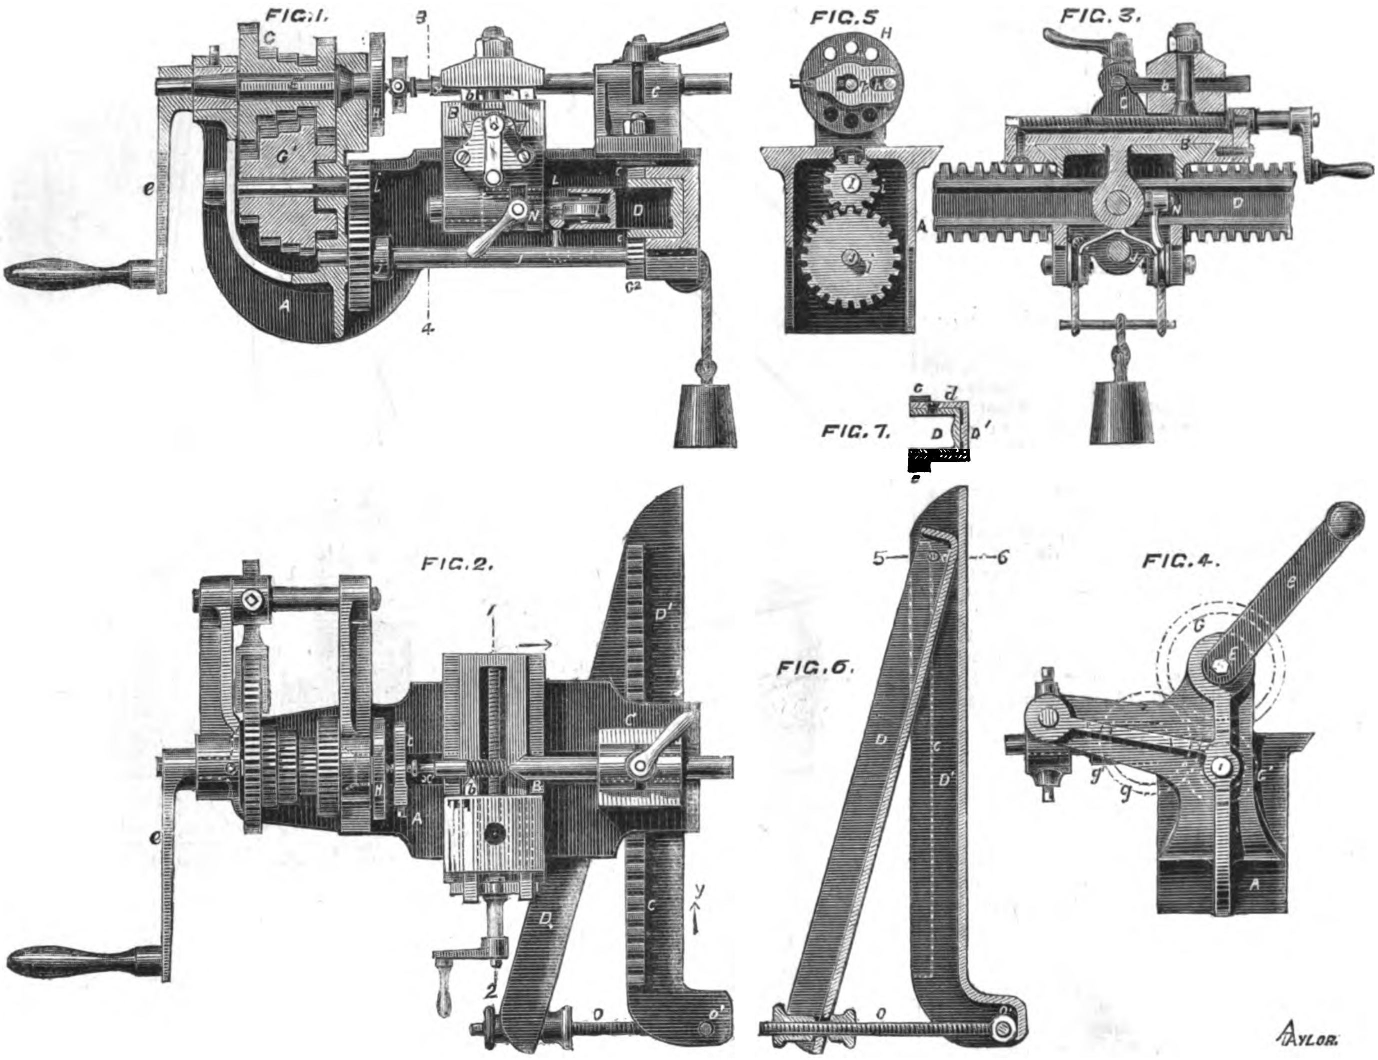
MACHINERY FOR CUTTING SCREW THREADS.

BY M. PAUL DE RESENER.



MACHINERY FOR CUTTING SCREW THREADS.

THE accompanying engraving illustrates an invention by M. Paul de Résener, of Paris, for cutting screw threads, whereby any variety of form of screws may be cut in the same machine by a simple adjustment, whilst the machine itself is cheaper and much more simple than those hitherto employed for screw cutting. The essential feature of novelty in this invention, which has been patented in England, is the employment of a travelling inclined plane, the angle of the incline being adjustable by means of a screw and adjusting nuts, for the purpose of imparting the necessary longitudinal traverse to the screw blank or to the cutter. The travelling incline is moved forward in a guide by means of a pinion in gear with a rack on the slide which carries the incline. This actuating pinion derives its motion from the mechanism which rotates the screw blank or the cutter, so that the rate of motion of the incline along its guide is always in proportion to the speed of rotation of the screw blank or of the cutter, and hence a spiral or screw thread will be produced upon the blank. By varying the angle of the incline, or by altering the speed of rotation of the screw blank or of the cutter, or by combining both these changes, screws of any desired pitch or number of threads may be cut without the necessity of employing the numerous change wheels requisite in ordinary screw-cutting lathes. Fig. 1 of our engraving is an external elevation and partial section, and fig. 2 a corresponding plan of a lathe, to which the inclined plane is adapted for screw-cutting purposes; fig. 3 is a transverse vertical section taken through the centre of the slide rest along the line 1—2, and looking in the direction of the arrow (fig. 2); fig. 4 is an end elevation of the driving gear; fig. 5 is a transverse section taken along the line 3—4 (fig. 1); and figs. 6 and 7 are detail views, showing the adjustable inclined plane.

The machine is composed of a frame A, carrying the whole of the mechanism, a slide rest B, the back centre C, and the adjustable inclined plane D. The main shaft E, which may be turned by hand, by means of the handle *e*, carries the gearing G and a chuck H. An intermediate shaft I carrying corresponding cone gearing G [1], actuates the lower spindle J, through the intervention of the wheels *i* and *j*. On the spindle J there is mounted a pinion *c* [2], which gears with one of two racks *c c* [1], in connection with the adjustable incline D. The adjustable incline (figs. 6 and 7) consists of a U-shaped bar, hinged at *d* into another U-shaped iron bar or guide D [1], carrying the racks *c c* [1], on its upper and under surface. At the opposite end to the hinge, these two parts D and D [1] are connected together by a screw *o* fixed at *o* [1], and passing through the adjustable incline D. The screw *o* is provided on each side of the incline with a milled headed nut, so that the distance between the plane D and the bar D [1] may be increased or diminished as required. The inclined plane thus arranged is mounted in a guide A [1] (fig. 1) formed in the frame A, so that one of the racks *c* [1] will be in gear with the pinion *c* [2] fast on the spindle J.

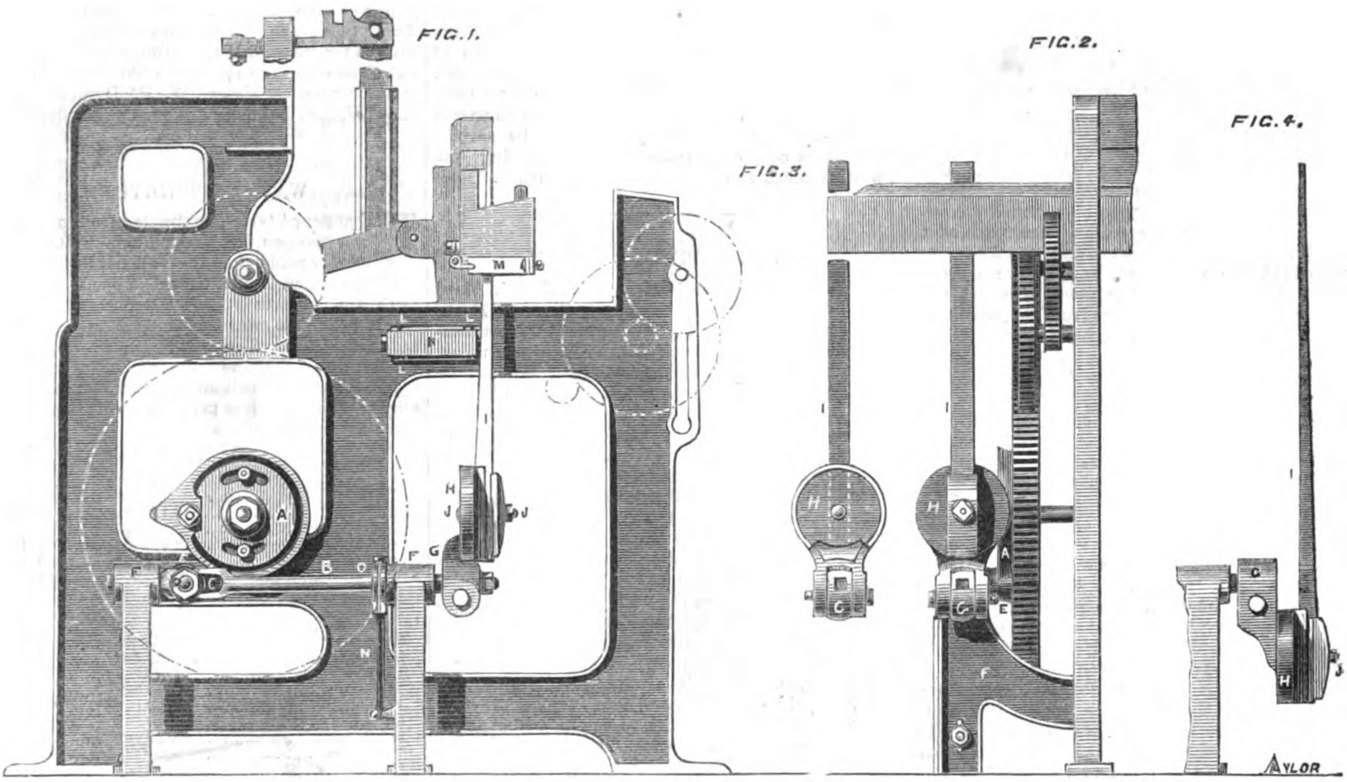
The inclined plane D acts on the slide rest B in the following manner:—The slide rest has a socket cast upon it, in which is fitted the shank of a roller carrier L, the roller *l* of which is in contact with the inclined plane, as the position of the roller has to be altered for each different pitch of screw. The carrier L is made adjustable and is maintained in its place by a gripping ring provided with a tail piece having a screw thread formed on it, which is secured by means of the hand nut N. The counterweight N [1] tends constantly to draw the roller carrier L with the slide rest B in such a direction as that the roller *l* may be always in contact with the face of the inclined plane D. A small intervening space separates the two sets of gearing G and G [1], which can only operate through the intervention of the intermediate pinion *g* mounted in an adjustable arm or carrier *g* [1], shown clearly in fig. 4, which may be moved vertically and horizontally as required. On rotating the handle *e* two wheels of the sets of gearing G and G [1] transmit motion to the spindle J, which by means of the pinion *c* [2] actuates one of the racks *c c* [1], which causes the bar D [1] to move in the direction of the arrow *y* (fig. 2), consequently the inclined plane D (the angle of which in relation to the bar D [1] has been adjusted) presses the roller *l* and with it the slide rest B, the tool *b* of which acts on the screw blank *x* secured between the centres of the machine, as in an ordinary lathe.

As the relative speeds of the shaft E and the rack *c* are the same, it follows that if the angle or inclination of the inclined plane D be varied by means of the adjusting screw *o*, the traverse of the guide D [1] being also increased or diminished, the spirals formed by the cutting tool will be at greater or less intervals, and consequently the pitch of the screw thread will be varied. The two sets of gearing G and G [1], serve to change the relative speeds of the shaft E and the rack *c*, in order to cut screws of a given number of threads. In order to cut screw threads in the reverse direction, it is simply necessary to reverse the position of the bar D [1], when the rack *c* will then be brought into gear with the pinion *c* [2] of the shaft J, and to change the direction of rotation of the shaft E. When cutting double or multiple threaded screws, one thread is first cut, after which the position of the pin *h* in the plate or chuck H, against which the dog *t* presses, is changed in order to cut a second thread, and again for a third, and finally a fourth thread; in each case of course the inclined plane D with its guide D [1] is brought back to its starting point again.

M. de Résener has also applied his adjustable inclined plane to a portable tool or screw stock, which may also be employed as a universal screw-cutting machine by attaching it to a work bench.

METHOD OF WORKING UNDER-PICK LOOMS.

BY MESSRS. J. GREGSON AND W. MONK.



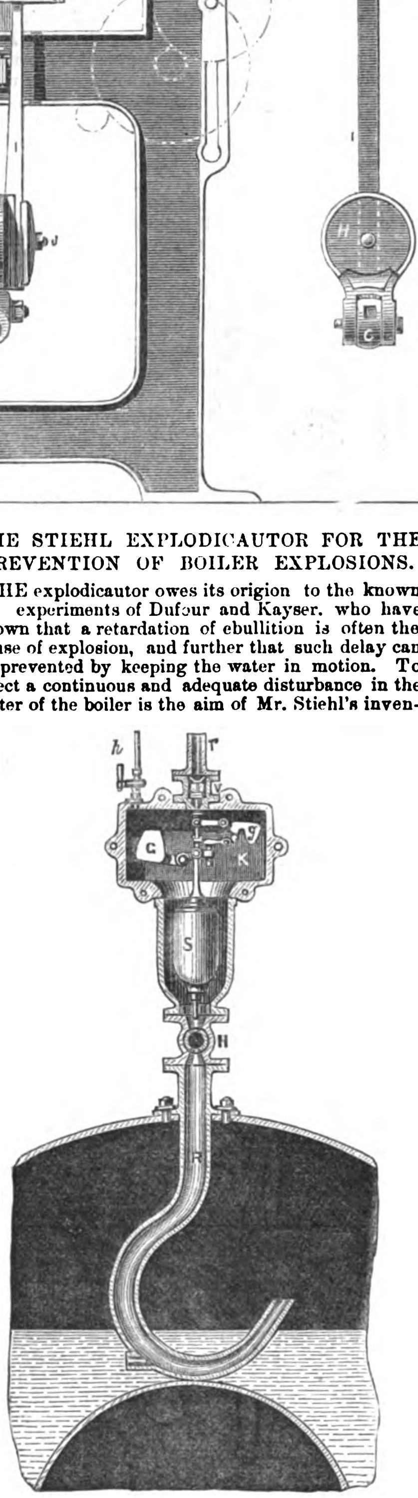
WORKING UNDER-PICK LOOMS.

MESSRS. J. GREGSON AND W. MONK, of Preston, machinists, have patented some improvements in looms, which refer to the method of working under-pick looms. They work them by a metallic pick motion on each end of the tappet shaft, and which is obtained by a cam on each end of the tappet shaft. The cams act on a bowl working on a stud connected with an horizontal picking shaft, to the ends of which is attached a swivel or universal joint, with catch box for holding the picking stick. In our engraving, fig. 1 is a side elevation of the loom showing the end of the tappet shaft on which is screwed the cam A; it likewise shows the side elevation of the picking shaft B, in which is a slot C. This slot is for regulating the stud D and bowl E for picking. F F are brackets for carrying the same. G is a universal joint, attached to which is a catch-box H, into which is fixed the picking stick I by the bolt J. Fig. 2 is a front view of the same. Fig. 3 is a back view of the universal joint, catch-box, and picking stick. Fig. 4 is a side elevation of a universal joint and catch box reversed to give a longer throw to the picking stick when required. K, in fig. 1, is a buffer strap for the picking stick to buff against, which projects from side of frame and is tightly suspended and stretched from L to L; M is likewise a strap attached to a spiral spring to prevent the rebound of the shuttle. N is a spiral spring to bring back the picking stick to its original place after picking; this spring is attached to a boss *o* on shaft B. The action will be through the cam on the tappet shaft B to the bowl on the picking shaft, and thence through universal joint, catch box, and picking stick to shuttle box. By these means a firm steady motion is obtained, and a great number of mechanical appliances, leather strapping, and checks are dispensed with. There will be but little wear and few breakages, the cloth will come off free from dirt or black oil, and, from the steadiness of the loom, the cloth will be better woven.

We understand that looms on this principle have been working in many places for some time past and are giving every satisfaction. They are found to be more durable, and to have less wear and tear than those upon the ordinary system. With these improvements there are said to be fewer breakages; they are easily applied, and effect a great saving in leather and other material. The cloth is clean and free from all black spots and dirt, and less power is required to drive the loom than is generally required.

THE STIEHL EXPLODICAUTOR FOR THE PREVENTION OF BOILER EXPLOSIONS.

THE explodicautor owes its origion to the known experiments of Dufour and Kayser, who have shown that a retardation of ebullition is often the cause of explosion, and further that such delay can be prevented by keeping the water in motion. To effect a continuous and adequate disturbance in the water of the boiler is the aim of Mr. Stiehl's invention.



The principle is that a quantity of water is sucked up and then again dropped down from the obtained height. The construction of the instrument will be more clearly understood from the annexed engraving. On the upper end of the tube R, which is outside of the boiler, a kind of box is constructed containing the swimmer S, which is partly balanced by the weight G. In the upper part, K, of the box there is also another weight *g*, attached to the lever *b*, which is arrested by the catch *k*. A safety valve V, and a cock *h*, are on the box. The space above the valve communicates by means of a little tube *r* with the vapour-room in the boiler. As soon as the cock *h* is opened, the water from the boiler ascends in the tube R, and lifts the swimmer S, whereby the lever *a* frees the catch *k*. The liberated lever *b* pushes against the valve V, and opens the same. The steam enters the box K, and the accumulated water falls back into the boiler. The swimmer then draws the lever *b* into its original position, the valve closes, the catch sets again, and the process begins afresh. By means of the cock *h*, the number of lifts can be regulated. Below the swimmer box as well as in the steam passage to the valve is a cock. The two cocks make a separation of the apparatus from the boiler possible, thereby allowing eventual repairs without any inconvenience. The following advantages are pointed out—First, the apparatus works even at overpressure of 1½lb. per square inch (0·11 kilo. per square centimetre). Secondly, the disturbance caused in the water is equally intense be the tension high or low. Thirdly, the adjusting of the apparatus is exceedingly simple and safe whether there be few or many lifts. Fourthly, as to the consumption of steam, it may be said that the same is small. Three to five lifts per minute will be sufficient to properly stimulate the stagnant water. Experiments have shown that 80 cubic inches (1·32 litres) per lift is the average of steam used. Thus the apparatus would only use 7lb. of coal in 24 hours. It is hence to be recommended that the explodicautor be kept at work at all times, thus preventing accident by neglect. The cock *h* may, according to more recent observations in ordinary cases, be kept closed, since the condensation of the steam in the upper part of the box is sufficient to set the apparatus going with fifteen lifts per minute. Fifthly, there is little or no wear and tear. Sixthly, there being no stuffing-box, the cost of maintenance are equal to zero. Lastly, access is gained to all loose parts by removing the lid of the box. The apparatus has a height of 40in. (1·046 metres) above the boiler, 12in. (315mm.) to 16in. (420mm.) width. A 4-inch (105mm.) hole in the plate of the boiler is sufficient to pass the tube R. Four conic steel screws, which are furnished with the apparatus, serve to fit it on. The explodicautor has been tried by Herren Forstmann and Hoffman, and G. Baedeeker, at Essen. According to their experience, it works at all tensions down to 1lb. per square inch (0·07 kilo. per square centimetre) with the same amount of certainty. The apparatus is patented in Prussia, England, France Belgium, Austria, Saxony, and Russia.—"Zeitschrift."

A SHOCK of an earthquake was felt at Bologna, on Saturday afternoon, which set the bells ringing and stopped the clocks, but fortunately did no further damage.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

AT an ordinary meeting of the above Society, held on the 9th inst., Mr. W. Forsyth Black, C.E., in the chair, an interesting paper on steam and other power hammers was read by Mr. Frederick H. Roberts, C.E. (member of Council).

The author referred in detail to some of the earlier machines, such as the helve or tilt hammers used for shingling, forging blooms, and shafting, tilting steel, &c., but, as this class of machine depended, to a great extent, for raising the hammer and its connections either through the direct medium of cams, eccentric or similar arrangements, it followed that the power required to work them was extremely large, and the parts of the machine itself very heavy and cumbersome to withstand the consequent strains. It was also found that the larger the mass of metal to be worked, the lighter the blow given, and, conversely, the smaller the mass, the heavier the blow; it was, therefore, ill adapted for heavy forgings. The invention of the steam hammer solved the difficulty which was found to exist, and to it, to a considerable extent, is due the perfection obtained in all classes of machines where ponderous forgings are found to be absolutely necessary.

The first idea with reference to the steam hammer the author traced as belonging to that great engineer, James Watt, who obtained a patent in 1784 for heavy hammers or stampers for forging iron, copper, or other metals without the intervention of rotative motion, by fixing the hammer head either directly to the piston or piston rod of the engine. Another patent followed this in 1806, by a Mr. Deverell. He proposed to admit steam underneath the piston of an engine by means of a valve, and during its up-stroke the air at the top of the piston was compressed by the pressure of steam beneath, which was released at the proper moment. The compressed air on the top of the piston, in addition to the gravity of the hammer head, was to give the blow. But neither of these ideas were put into practice at that period, and it was not until 1837 that any practical design was put forward for a steam hammer, and then by Mr. Nasmyth, of Patricroft, who urged its superiority for working metal over all other machines, but was unable to procure its adoption until about 1840, when he found that M. Schneider, of Creusot, profiting by his design, had constructed a machine on his plan. In 1842 he obtained a patent for his steam hammer, and from that time it became a recognized power, and a necessity in all works of importance. The facility which it afforded for executing all kinds of forging had the effect of greatly increasing the quantity of work to be done, and effecting a material saving both in time and labour.

The steam hammer, as originally constructed, required the valves being worked by hand, which left the machine in the power of the workman to give proper efficiency. The valves were also very difficult to work. This plan answered for the time for small machines, but where rapid motion was necessary, and for larger hammers, it was unsuitable. Several designs for self-acting motion, therefore, followed in quick succession. The author then referred to the different designs that had been introduced for this purpose. In the ordinary self-acting hammer, the man has to watch the metal under operation, and, as its form and position change, he must set his valve gear to suit as near as possible. The author considered that the motion, to be properly self-acting, should be independent of the workman as regards the adjusting of the gear to suit the varied thicknesses of the metal on the anvil; and, in order to obtain the full force of the blow, it should reverse simultaneously with or immediately after the blow is given, and at whatever point in the stroke the blow takes place. He considered that was accomplished in Sturgeon's double-action hammer, where the blow itself was made use of as the agent to work the valve, and described the mechanism employed; also the various types of double-action steam hammer; likewise the numerous modifications and improvements effected. The author then spoke as to the specialities of the heaviest classes of steam hammers of modern date, including those of Mr. Ramsbottom's design; likewise those erected for M. Krupp, at Essen.

With reference to machines of a lighter class, the author described the various designs for power hammers, and referred to the patent pneumatic hammer, several of which he had erected, and which are specially adapted for general smithy work, or light forgings, planishing and beating out metal, &c. It is extremely simple in action, working by means of the alternate exhaustion and compression of air within two cylinders, in one of which is a piston, to which the hammer head is connected by means of the piston rod. By opening a small valve, the vacuum formed within the cylinder is destroyed, and the blow weakened or stopped instantly, according to the amount of the valve opened. These machines are capable of working up to 500 blows per minute when required. At some future opportunity, we purpose to refer further in detail to this machine, and to illustrate the general arrangement, as adopted by several engineers and coppersmiths. The meeting was well attended, and a good discussion ensued.

THE BERMUDA DOCK.

THE following notification from Captain May, respecting the progress of the Bermuda Dock, has been issued by the Admiralty:—"'Northumberland' at Sea, Start Point, N.W., fifteen miles, June 25.—I beg to forward, for the information of the Lords Commissioners of the Admiralty, the following particulars relative to the Bermuda Dock:—Everything thus far has turned out most satisfactorily. The dock steers remarkably well; the towing cables led through the stern ports of the towing ships seem but little to affect their steering power, their rudders not being paralyzed, or even partially so, as was by some people anticipated. The consumption of coal on board the 'Northumberland' and 'Agincourt' is at present about 45 per cent. per hour, the dock being towed about five knots, the weather being calm, water smooth, and circumstances most favourable. The 'Terrible,' though towing astern of the dock, is not a dead drag, as her paddles are kept revolving slowly at an hourly expenditure of about 10cwt. of coal. If all goes well, as there is reason to anticipate, I shall not communicate with Lisbon. I might remark that I took the Bermuda in tow without the assistance of any lighters floats. The dock was brought under the 'Northumberland' stern, whilst she was lying at anchor, and the 26-inch cables readily hauled on board. Before leaving Sheerness, these cables were securely lashed on board the Bermuda to the riding bits amidships at 50 fathoms length, this being done to prevent the dock yawing in the narrow channels. Finding the dock was steering so satisfactorily, I left well alone, and do not intend to tow to the full scope, unless compelled to do so by bad weather or a heavy swell. The weather has continued very hazy since the flotilla left Sheerness; no observations have been obtained, or land seen since leaving Dover. I have, therefore, dispatched he 'Medusa' to the rendezvous off the Eddystone, to warn the 'Helicon' and 'Lapwing' of our approach and supposed position. Should I not find those vessels, I have directed them to follow down the track laid down by the hydrographer. Everything goes most satisfactorily, and the following are the quantities of coal remaining on board the larger ships at 8 a.m. this day:—'Agincourt,' 966 tons; 'Northumberland,' 1,026 tons.—I have, &c., (Signed).

"C. H. MAY, Captain and Senior Officer."

THE ROYAL CORNWALL POLYTECHNIC SOCIETY.

FEW, if any, local scientific associations confer the amount of benefit upon the surrounding population that the above Society does upon the industrial classes in Cornwall. It is, therefore, with much satisfaction that we announce its thirty-seventh annual exhibition, which will be opened at a very convenient date for the visitors to the meeting of the Bristish Association, at Exeter, viz., on the 27th of August. As usual, medals and prizes will be awarded by the Society in the mechanical departments for exhibits connected with natural philosophy, chemical analysis, mechanical and other scientific inventions and improvements, models of machinery not displaying invention, and naval architecture. The Society offers every inducement to exhibitors, by making them no charge for space. To the Society's long lists of special premiums another has this year been added of considerable importance. The efforts which have recently been made in Cornwall to introduce machinery for boring and tunnelling purposes as a substitute for hand labour is well known, and for several years past, the exhibitions of the Royal Cornwall Polytechnic Society have afforded ample evidence of the progress made in that direction. To stimulate further exertions in the matter, premiums of £10 are offered by Capt. Wm. Teague and the shareholders in Tincroft Mine, and £5 by the Society for the best practical suggestions (with models or drawings) as to the motive power to be employed in driving boring machines in Cornish mines, including the method of conveying the power of the machines. The council have fixed August 7 as the the last day for receiving applications for space, and intending exhibitors should put themselves in communication with the honorary secretaries, Messrs. W. P. Dymond and A. Lloyd Fox, at Falmouth, as soon as possible.

WAR EXPENDITURE.

THE annexed table is extracted from a paper on war taxation, by Mr. William Stokes, which was recently read before the National Reform Union at Manchester. Mr. Stokes' object was to set forth the permanent consequences of what he terms profligate war expenditure and periodical invasion panics. The conclusion he draws from the figures is that the industry, trade, and manufactures of Great Britain are more shackled and burdened by needless taxation than those of any other nation:—

	National Debt.	Amount per head.		
	£	£	s.	d.
1. Ducal Hesse	228,916	0	5	4
2. Sweden	4,114,880	1	0	0
3. Norway	1,854,157	1	1	10
4. Chili, S. America	2,933,405	1	15	0
5. Prussia (1866)	42,123,064	1	15	8
6. Turkey	69,142,270	1	19	1
7. Oldenburgh	621,585	2	1	2
8. Electoral Hesse	1,485,892	2	9	6
9. Brazil	30,762,289	3	1	3
10. Hanover	6,423,955	3	3	6
11. Russia	274,544,770	3	14	1
12. Wurtemburg	7,033,911	3	19	6
13. Saxony	9,912,049	4	4	10

28. Great Britain	797,031,650	26	10	0

THE ROYAL HORTICULTURAL SOCIETY.

THE President and Fellows of the Royal Horticultural Society gave a very interesting entertainment yesterday week in their conservatory, which was lighted up with taste and effect. During the evening, the members of the St. Cecilia Choral Society, under the direction of Mr. C. J. Hargett, performed a selection of glees and part songs, the distinctive feature of the programme being that all the pieces, except one, were the compositions of English masters. The great tent, with its groups of rhododendrons, was illuminated during the evening with coloured lamps and the lime light. The combination of the two descriptions of lights, however, was not quite a success; the effect would have been much better with the pure light. The great rose show took place last Tuesday, and the exhibits on that occasion fully equalled the display of any former period. The cut specimens were most numerous, but there was also a fine show of pot roses. The principal prizes were carried off by Messrs. Paul and Son, Mr. C. Turner, Mr. J. Keynes, and Mr. B. R. Cant.

FORBES'S LAST NEW RIG FOR SHIPS.

IN the course of this work ("Nautical Magazine") we have seen a change in the sails of our merchant shipping, which, from its extended adoption, has evidently answered its intended purpose. The same inventor (Mr. R. B. Forbes, of Boston), has now sent us another child of his brain, and one which, great as the former was in the arrangement of a ship's sails, seems likely to produce a still greater revolution in the method of bending and furling these light appendages to a ship's furniture. The arrangement by which this is effected is so thoroughly novel, and one which so effectually reverses all former proceedings of duties, that although some advantages are evident (such as a flatter sail and an easier furl), it would be premature to express at present an opinion of his system. And we shall, therefore, content ourselves, as in duty we are bound to do, by allowing Mr. Forbes the opportunity of explaining it himself:—"London, May 22. Dear sir,—In the first place I must introduce myself anew to you, as the originator of the double-top-sail rig, for which you kindly allowed a place in the "Nau-

tical Magazine," in 1851. I desire to call the attention of seamen, shipowners, and others to a new mode of arranging the same proportions of sail, rig, &c., as illustrated by the auxiliary packet ship the 'Massachusetts,' built under my orders, and after my plans in 1845. By this method, all my square sails, except courses and sky-sails, or royals, are bent by the foot and not by the head, as at present; my lower yards are slung or parelled just above instead of below the eyes of rigging and stays; top-sail yards are slung or parelled to a prolongation of the lower mast through the cap, also just above the eyes of backstays and stays and not under or below them, as at present. I bend to the head of the sail a spar about a quarter or one-fifth of the length of the yard above it, in the middle, and leave a space (when sail is set) between the said spar and the yard, so as to clear the stay, and not to cramp the yard in bracing sharp. Sky-sails clew up and lower as usual; all other yards are fixed by slings, and move only on parells. Courses come down to the deck; other sails come down to the foot. All the square sails of a ship, by the new method, are bent by the foot to the yards and not by the head, as usual; the yards (except the upper one, say sky-sail or royal) are permanently slung or parelled to their respective masts, just over or above the stays, and the eyes of the rigging and backstays, and not under or below them, as at present. This mode of bending sails and slinging their yards involves a wholly new arrangement of the standing rigging and the position of the yards. It is proposed at no distant day to give a full description of this new rig, with diagrams. The sails below the upper ones of all consequently furl on the yard at their foot and not at their heads, and trice up instead of 'clewing' up, as usual. The courses come down to the deck, and are there reefed or furled, except in light winds, when they may be hauled up, as usual. The principal advantages derived from this rig are, dispensing with tyes and sheets, better setting of the sails, facility for furling or reefing by few men, especially the courses; yards brace almost fore and aft, which is a great advantage in steamers. So great a deviation from old established customs will, no doubt, meet with much criticism, and, as usual, opposition, especially among those who contract for building and equipping ships. Having had much experience in fitting ships, it enables me to propose this new system of rigging ships with confidence, for no seaman who has seen the preliminary sketches has made any grave objections to it.—I am, your obedient servant,

"R. B. Forbes, of Boston, U.S.A.

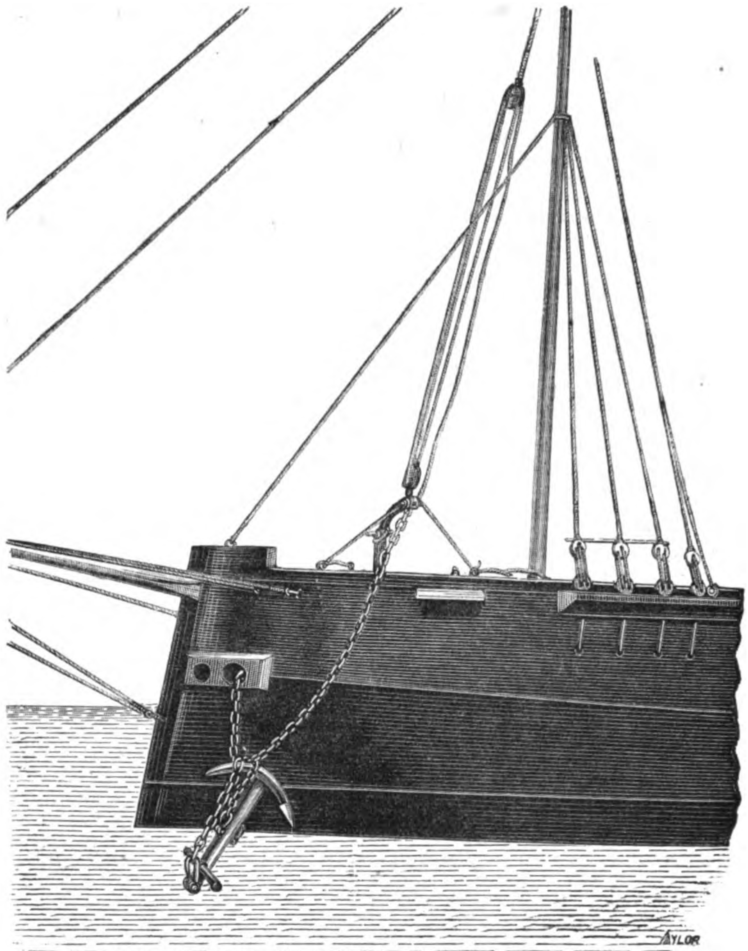
"To the Editor of the 'Nautical Magazine.'"

RAILWAYS IN THE UNITED STATES.

THERE were in operation in all the States on January 1, 1869, 42,255 miles of line, the cost of which, at 44,000dols. per mile, equalled 1,800,000,000dols. The total amount of net tonnage passed over them in 1867 is stated at 75,000,000 tons, having a value of 10,472,250,000—a sum equalling six times their cost and more than four times greater than the whole amount of the National Debt. It is said that the tonnage is understated, and cannot be less than 100,000,000 tons, which would be rather more than the quantity of minerals carried on the lines of the United Kingdom. It is believed that at least 5,000 miles of new railroad will have been opened in the United States in the course of the year 1869. Already the returns show a mile to every 876 of the population. The earnings of the American railroads, says the "New York Times," are very much greater than those of the English. The railroad mileage of that country in 1867 was 14,247; in the United States, 39,276. The cost of the former equalled very nearly 2,500,000,000dols., that of the railroads of the United States, for the same year, 1,700,000,000dols. The gross earnings of the English roads, upon their cost, equalled 7·86 per cent.; those of the United States very nearly 25 per cent. The English roads, however, have a great advantage over our own in operating expenses, their net earnings, as a rule, fully equalling one half of the gross receipts. In this country the net cannot be estimated at over 30 per cent. of the receipts. The average gross earnings per mile (per mile travelled by trains) of the railroads of the State of New York in 1867 was 2dols. 30cents per mile; those of Great Britain, 1dol. 25cents. But the cost per train-mile of running trains (the "working expenditure") was 166cents on the New York lines, and only 61dols. 37cents on the British. The most startling difference in the items of cost is in the the matter of fuel; the cost of the same in this country being 21·60 per mile, in England 3·42 per mile. Coke is almost exclusively used upon English roads, upon our own wood or raw coal; the former is a very expensive fuel, while the latter is very destructive to the engine. We excel all nations in the art of construction, and in securing the largest revenue for a given service, but not in the economy of working. Our inferiority in this respect is, however, largely due to cost of material, which, for the more important articles, is twice greater in this country than in Europe.

METHOD OF FISHING AND CATTING ANCHORS WITH ONE HOIST.

Fig. 5.



RED LEAD.

RED lead, an important ingredient in the manufacture of flint glass, has long been a "staple" of Birmingham industry. Formerly, glass makers' red lead was obtained from Derbyshire, but the quality was inferior, and imparted to the glass an objectionable shade of colour known in the trade as the "Derby blue." For many years, Blair and Stephenson, of Tipton, secured a monopoly in the supply of this commodity. In the year 1817, a manager of this firm, Mr. Boyle, entered into partnership with Adkins and Nock, of Smethwick, as manufacturers of red lead, and when Messrs. Blair and Stephenson retired from the trade, this firm became the largest producers. We ("The Engineer") are indebted to Mr. Henry Adkins for a description, which follows, of the process of manufacture. A quantity of lead is placed on the bed of a reverberatory furnace of a peculiar construction, and exposed to a high temperature, while the metal is constantly agitated by striking it upon the surface with a rake. A combination takes place between the lead and the oxygen of the atmosphere, and the oxide of the lead thus formed is removed by the rake to the back of the furnace. These operations are continued during a period of twelve hours, at the expiration of which time any metallic lead which may have failed to become oxidized is removed, and the remaining oxide is exposed by constant turning to the action of the air, and at the termination of a further period of twelve hours is withdrawn from the furnace. The substance thus produced, which is called litharge, is now ground into an impalpable powder with water, and flows into a series of tubs, where it is kept in a state of agitation by a revolving stirrer, furnished with arms. The particles of metal which have escaped oxidation, having a greater specific gravity than the oxide, remain in the stirring tubs, while the oxide of lead passes on into another series of tubs, where it subsides from the water. The supernatant water is afterwards removed by a syphon, and the moist litharge transferred to a reverberatory furnace, where it is exposed to the combined action of a low temperature and a current of air for a period of twenty-four hours. During this process, the litharge enters into combination with a further quantity of oxygen, and minium or red lead is produced. The manufacture is completed by passing the substance through a revolving cylinder of wire gauze, to remove any lumps that may have been formed, or any large particles of foreign matter with which it may have become intermixed during the previous operations. The principal manufacturers in this district are Messrs. T. Adkins and Co., Smethwick; Messrs. Lloyd and Co., Smethwick; and Messrs. Burr, Brothers, and Co., Shrewsbury.

LARGE BLAST AT LIME POINT, CALIFORNIA.

THE operation of blasting off the rocky headland of Lime Point, opposite Fort Point, and forming the northern entrance to San Francisco Bay, for a heavy water battery, has been conducted under the direction of Colonel G. H. Mendell, U.S. Engineer Corps. Two blasts have already been made; one with about 10,001b. of powder, and a second with 24,0001b. This second blast is supposed to have been the largest ever used in military engineering, and moved about 80,000 tons of rock. This manner of moving large masses of rock was first introduced by Field-Marshal Sir John F. Burgoyne, in the operations for constructing the immense breakwater works at Holyhead, England. It was subsequently used for blasting a roadway around the cliffs of Dover for a railway. The philosophy of the blasting is, that of tunneling into the base of the rocky headland and making several chambers to hold the powder, and then blocking the tunnel up again and firing the powder by electricity. One charge in the operations at Dover contained 18,0001b. of powder, the largest known outside of the Lime Point operations.

The headland at the northern side of the Golden Gate is called Lime Point, not because of any lime rock forming the cliff, as almost every kind of rock is represented, except lime rock. The white appearance of some of the low rocks is due entirely to bird lime. The Government purchased 1,900 acres from S. R. Throgmorton, for 125,000 dollars, in currency, which included Horseshoe Cove.

The last blast was at the extreme point of the cliff, nearly facing Fort Point. The company which assembled to witness it went on board the steam tug "Katie," belonging to the Engineer Department, consisted of General Alexander, United States Engineers, Prof. Le Conte, of the University of Cali-

fornia, Prof. Davidson, United States Coast Survey, numerous Army officers and their ladies and invited guests; in all, about fifty. On arriving at the snug landing constructed by Colonel Mendell, on the easterly shore of the Point, by filling in a causeway of 100ft. or 200ft., to the Needles, to break the southerly swell, the company walked to the Point, a distance of about 2,000ft., in a southerly direction, to examine the locality. About 60 workmen were busy in removing the rock and earth moved by the previous large blasts. At the Point, a tunnel had been run in a north-westerly direction, into the base of the hill, a distance of about 30ft., where a chamber was formed on the right, to contain 3,000lb. of powder; thence the tunnel ran in a direction south of west 31ft., where a chamber was formed on the left for 6,000lb. of powder; thence on the same line 45ft., where the third chamber was formed to contain 7,500lb. These chambers were about 5ft. by 7ft., to contain from 125 to 130 cubic feet.

When all were chambered out, a board partition was put up in front of each chamber to hold the powder. The greatest care was used in placing the powder in the chambers. The men wore the wooden French sabots, or bandaged their feet in bagging. The barrel of powder was opened at the mouth of the tunnel, and carried into the chambers in sacks, the men groping their way into the dark tunnel and delivering their dangerous burden to the foreman, who emptied it in one immense bin in the chamber. At a certain stage of the filling up, eight cartridges were distributed at different points in the mass; each cartridge having an electric wire leading to the central wire connected with the magnetic machine outside. As fast as these chambers were filled, they were sealed up with clay and the tunnel tamped with the same material, the wires for firing the mass leading through a small wooden box at the bottom of the tunnel. These wires, two in number, were of copper, on an insulated wire to convey the electricity to the mass of powder, and a plain wire for the return current; one connected with the positive and the other with the negative pole of a powerful Beardslee magneto-electric machine, located in a secure place outside and several hundred feet distant. The company went on board the steam tug, a few hundred feet distant, to witness the effect of the explosion. On waving a white handkerchief by Colonel Mendell on shore, the machine was put in rapid motion by a crank, the positive and negative poles of the battery were connected at half-past 3, when the explosion took place with a heavy dull sound, and an immense mass of rock and earth was thrown into the air about 50ft., and the whole face of the cliff came crashing down to the base and tumbled into the sea. Heavy masses came down at intervals, as they were loosened. The company went on shore and examined the result of the blast, which proved far more extensive than it appeared from the steamer. The cliff had been blasted off for about 200ft. along its face and for about 175ft. in height, with an average depth of about 60ft. The mass of rock and earth thrown down is estimated at 60,000 tons. The 60 workmen are able to move about 10,000 to 12,000 cubic yards monthly, and fill in on outside of the plateau, which is about 20ft. above low tide.

The kind of batteries which will be placed here is undecided, but they will not be of masonry. Experiments are now being made with a view to putting in iron batteries. These will be erected on the solid rock, some little distance back from the front, and will probably consist of the 15-inch and 20-inch Columbians already in use in the Government arsenals, which will throw shot of several hundred pounds weight, according to shape, for a distance of four to five miles. The range of the battery will be very extensive, embracing nearly three-quarters of a circle, and will occupy about 500ft. east and west, and about the same distance north and south, on the eastern face, which commands Raccoon Straits, Angel Island, Alcatraz Island and the southern shore of the entrance to the Bay. The work is prosecuted slowly, as the present appropriation for this purpose is too small to allow of rapid work.—San Francisco paper.

THE PUTNAM MACHINE WORKS.

THESE works, which are located at Fitchburg, Mass., on the line of the Vermont and Massachusetts Railway, were instituted in 1854. Some three years since, the business having outgrown the capacity of their shops on Water-street, some twenty-six acres of land alongside of the railway track were purchased, and new buildings were put up at a cost of some 200,000 dollars. The new works, with their accessories, look to an almost indefinite extension of business, and are admirably arranged in every department, as may be gathered from the "American Railway Times." The main machine shop building is of brick, one storey high, 625 × 48ft., supported by 35 iron columns, 20ft. high in the centre. To these central columns are fastened the main shafting for driving the machinery. This building has 284 windows, 500 gas burners, and is warmed by over six miles of steam pipe, and is devoted to seven different departments of work, although the whole is free from any partition or other obstructions to the sight. Each separate department has a large L built out at the right hand for the erection and delivery of machinery, the manufacturing being all carried on within the main building. Six of these L's are 36 × 52ft. and one is 44 × 52ft., and in these are powerful cranes for handling the heavier articles. On the left hand side of the main building, and immediately opposite the large L's, are small L's, 12ft. square, appropriately fitted up as offices for the heads of the different departments of work, thus leaving the main building, with its forest of machinery and mechanical devices, free from all obstruction. Each of the seven different departments has its appropriate work; thus in one we find the blacksmiths' shop, with its forges and heavy hammers. The next is devoted to the manufacture of steam engines, from 150-horse power down to any required size; in the next are made drills and planers of all capacities. The next is devoted to lathes; in one is made the Burleigh rock drill, and so on, the establishment turning out all kinds of machinists' tools, shafting, and mill and wood-working machinery.

At the front end of the long building is to be a handsome four-storey brick building, with a Mansard roof, for the general offices, halls, &c. This is as yet unfinished, but in one part of it we found a small, well appointed machine shop, fitted up for the exclusive manufacture of the smaller steel tools, taps, dies, reamers, cutters, &c. The gauges used here are the same as adopted by the United States Government. Parallel with the machine shop, and divided by a wide yard running to the railway track, are to be seen storehouses for iron, coal, and sand, all these being delivered directly from the cars; the foundry; the moulding room 54 × 130ft.; several furnaces capable of melting four tons per hour each; a large two-storey building 40 × 160ft., the basement of which is used for the manufacture of flasks and the storage of heavy materials, while the second storey is used for a pattern shop and for storing patterns. Then comes a brass foundry, 30 × 40ft.; a building for cleaning castings, 32 × 40ft., and several other buildings for various purposes, all arranged systematically for labour saving and easy supervision. This well-conducted establishment has grown up from small beginnings to its present magnitude, under the eye and personal supervision of the active manager of the works, Mr. S. W. Putnam, from whom the works take their name. They now employ some 250 men in the different departments of skilled labour, and the character of machines turned out are second to none in the country.

FIXED AND FLOATING DEFENCES IN AMERICA.

ONE of the chief technical military problems now before the nation, is, whether the majority of its heavier guns, designed for coastwise defence, shall be mounted on fixed or on floating platforms. We, U.S. "Army and Navy Journal," put this as a "problem," because on this subject there would seem to be a difference of opinion; since, at all events, the energies of some of our most famous and experienced officers are concentrated on the various means of patching up, thickening, and otherwise strengthening, our old forts, which were constructed, and very admirably constructed, too, with a view to less formidable attack than that which they now have to expect. If guns are planted on fixed platforms, it requires very little study to see that not only must they be mounted within very easy range of the channel they are designed to protect, and mounted also in such a way as to give great facility of manipulation and accuracy of aim, but still further and of far greater importance, this channel itself must be blocked up by obstructions, in order to keep the enemy for a sufficient time under the range of the guns. Unless such obstructions are effectually placed, very obviously the attacking fleet will move by the forts, out of the range of the guns, and, aided by the inevitable confusion of battle, and the pall of smoke which settles on the landscape, this feat is never difficult of accomplishment. Guns in a fixed fort are, after all, as has been aptly said, very often a sort of "chained monsters," only to be feared within their reach; and hence it may be taken as an axiom that it is absolutely necessary to keep the enemy within their range, by some device, in order to accomplish the result desired. On the other hand, obstructing a commercial harbour is, in itself, not only so humiliating, but so injurious a device, that, very naturally, it should be one of the last resorted to. Take, for example, New York Harbour. Surely, the very last method to be taken for defending this harbour ought to be that of obstructing its channels. It would hardly be tolerated by the merchants of the city, and hence the natural anxiety to seek other means of defence. It may be stated, without fear of denial, that in every case where a fleet of steamers has endeavoured to run by forts, of whatever strength, and supplied with ordnance of whatever quantity and calibre, through an obstructed channel, they have always succeeded. So, for example, it was at Vicksburg, on the Mississippi; and again at New Orleans, when Farragut ran by Forts Jackson and St. Phillip; and again at Mobile, when the same officer ran past Forts Morgan and Gaines; and again in the Paraguayan war, when the allied fleet ran by Humaita. Indeed, the running of batteries on our Western rivers was almost an every-day occurrence. Who ever heard of Porter stopping for a fort, however powerful, if he could run by? The truth is that it became a mere question of expediency, in an unobstructed channel, whether to attempt to reduce a powerful fort by bombardment, or to run by it and capture the city or strategic points it was meant to cover. In this dilemma, our school of engineers have long maintained the necessity of mounting heavy guns for coast defence on movable platforms. The advantages of this scheme are apparent, both on the ground of efficiency and of economy. We do not, therefore, share the apprehensions sometimes indulged regarding the inadequacy of one or another improvement prepared for our fixed defences, since it is very clear that, when actual need arises, we can always call upon mechanical ingenuity to supply in the direction of movable defences, perfect protection for our harbours and coasts.

Correspondence.

BRIDGE v. TUNNEL.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—My attention having been called to a statement which has appeared in the newspapers of the 25th inst., that a deputation of the promoters of the proposed tunnel under the English Channel have waited upon the President of the Board of Trade to ask for a Government guarantee on a sum of two millions sterling, for the purpose of making experiments as to the practicability of such a means of communication with the Continent, and have represented to Mr. Bright that a commission of scientific men have reported in favour of the scheme, and that the French Government are waiting to see what action the English Government would take in the matter, I think it my duty, on behalf of the Anglo-French Railway Bridge Company, to state that I have never heard that such is the case; on the contrary, I am led to believe that the sympathies of his Imperial Majesty the Emperor of the French are with the company which I represent.

It is possible the commission may have recommended that the proposed experiments should be made, but it is quite certain that the Emperor has, personally, and uninvited, been to inspect the progress of the experiments now making (without Government aid) by the Anglo-French Railway Bridge Company, and that he expressed himself, after a lengthy examination of the details, much pleased with what he saw. It is obvious that his Majesty must feel great interest in the success of this grand undertaking.

The system of bridge building proposed by M. Boutet has been so far proved that two bridges have been built in France on his principle, and a bridge, with two spans of half a mile each in length, is in contemplation near St. Malo, the viaduct being a mile in length. These experiments have been made with money subscribed by English and French believers in the practicability of M. Boutet's system; and until it has been shown that their belief is unfounded, I submit that the promoters of a rival scheme ought not to receive Government assistance to enable them to do that which the Anglo-French Railway Bridge Company have done, and are doing, at their own expense.—I am, Sir, yours, &c.,

HENRY STEAD, Secretary.

Anglo-French Railway Bridge Company,
18, Old Broad-street, E.C., June 28.

[The report of the interview above referred to appears in another column, having reached us too late for insertion in our last.—ED. M.M.]

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—G. F. T.—R. B.—E. R.—G. W. H.—S. U.—J. T.—R. S.—T. E. K.—J. B.—R. W. and Co.—S. A.—G. W. R.—H. S.—R. T.—H. B.—P. and Co.—G. S.—H. T.—F. M.—J. D. and Co.—T. W.—K. and E.—F. J. and F. J.—S. E. K. C.—T. N.—E. F. B.—R. I.—G. E. P.—W. C.—R. H. D.—J. F. S.—E. T. H.—W. W.—H. R.—W. S.

Meetings for the Week.

MON.—Royal Institution.—General Monthly Meeting, at 2 p.m.

Naval, Military, and Gunnery Items.

THE first military district in Canada, the headquarters of which have been at Toronto, has been broken up. Major-Gen. Stisted and staff moved to the camp at Point Levis, and took the command of the troops on the fortifications from June 10.

THE inhabitants of Wimbledon having complained of the great crowd resorting to the camp on Sundays, there will be no admission to the enclosure on Sundays, July 4, 11, and 18, except by tickets, viz., 1. The usual members' pass; 2. The Wimbledon residential special pass; 3. Special Sunday passes issued through the officers in command of volunteer corps in camp. No carriages will be admitted.

THE monthly statement of the Bureau Veritas, of Paris, shows that in the month of May last, 190 vessels have been reported as totally lost. The list comprises 87 English, 25 American, 16 French, 14 North German, 10 Norwegian, 9 Dutch, and 5 Italian vessels, and 24 vessels sailing under various other flags. The total losses in the corresponding month of 1866 was 230; of 1867, 182; and of 1868, 171.

MESSRS. HENDERSON, COULBORN, and Co., of Renfrew, have launched a screw of 1,200 tons, on board which they are now fitting a pair of their high and low pressure engines of the collective force of 120-horse power nominal. The vessel, which has been named the "Blanche," has been built for MM. Mallet, of Havre. The "Mary Hamilton," screw, built by Messrs. W. Hamilton and Co., for the Turkish Government, has made a favourable trial trip.

LAST Friday some field telegraph waggons were started from Chatham for Aldershot Camp. It is understood that these waggons will in future accompany the troops in their field movements, and that they will be under the superintendence of Serjeant Ross, Royal Engineers, for some years connected with the telegraph office at Aldershot, and who has recently undergone a course of instruction in field signalling and telegraphy at Chatham.

THE Lords of the Admiralty have caused a circular to be issued authorizing officers, seamen, and marines on board her Majesty's ships to discontinue the use of the razor under certain restrictions. The hair of beard, moustachios, and whiskers is to be kept well cut and trimmed, and not too long for cleanliness. Care is to be taken that those officers and men who avail themselves of the privilege are not to be whimsical. The beard is not to be worn without moustachios, nor the latter without the former.

EVERY facility is afforded to the troops at Aldershot for learning to swim, and efficient measures for the safety of the bathers are put in practice. Bathing parades, in accordance with instructions contained in the "Queen's Regulations," and the divisional standing orders, will be held. Bathing pickets, consisting of two corporals and six privates, expert swimmers, will mount daily at the bathing places from 10 a.m. to 8.30 p.m., half to be on duty at a time.

THE annual distribution of prizes to the pupils on board the school frigate "Conway," stationed in the Mersey, was held last Friday afternoon. Mr. Childers, First Lord of the Admiralty, distributed the prizes. He was accompanied by Admiral Dacres and Captain Seymour. Her Majesty's gold medal for general excellence, awarded by the votes of the other pupils, was won by Frederick Fawcett; the Admiralty nomination to the naval cadetship by John F. Stuart; and her Majesty's second prize also by John F. Stuart.

MESSRS. W. C. MILLER and SONS, of Garston, floated the "Brazilian" screw steamer from their graving dock on the 24th inst., after having lengthened her 125ft. Her dimensions now are as follows:—Length between perpendiculars, 403ft.; breadth, 37ft. 9in.; depth, 35ft. 4in. She will be propelled by engines of 500-horse power, and steered with Skinners' vertical steering apparatus. With the exception of the "Great Eastern," this vessel is, we believe, of greater length than any other in the merchant service. She is said to be intended for the Suez Canal navigation.

EACH of the Royal dockyards at Keil and Dantzic has been supplied by Messrs. Merryweather and Sons, London, with one of their powerful double cylinder fire-engines, built at their works in Lambeth. The steam fire-engine sent to Keil dockyard is similar to that which gained the gold medal at the Paris Exhibition, in 1867, and discharges 1,000 gallons of water per minute to a distance of 250ft. As many as twelve jets may be thrown simultaneously. Each of the Royal Dockyards at Portsmouth, Plymouth, Woolwich, Deptford, and Chatham is also furnished with a steam fire-engine of similar power manufactured by the same firm.

IN the year 1868, the registerred shipping of the United Kingdom (exclusive of river steamers) employed in our home and foreign trade, comprised the unprecedented number of 22,250 vessels of 5,516,434 tons, employing 197,502 men, exclusive of masters, viz., 20,525 sailing vessels of 4,691,820 tons, employing 153,840 men, and 1,725 steam vessels of 824,614 tons, employing 43,662 men. At the end of the year there stood registered as belonging to the United Kingdom 28,444 vessels of 5,780,530 tons; viz., 25,500 sailing vessels of 4,878,236 tons, and 2,944 steam vessels of 902,297 tons. This is the highest tonnage ever recorded. There was built and registered in the United Kingdom in 1868, 879 sailing vessels of 300,477 tons, and 232 steam vessels of 79,096 tons.

WE have to record the death of Serjeant William Vile, one of the few veterans left who were present at the ever memorable battle of Waterloo. He was born May 4, 1787, and at an early age he joined the 49th Regiment of Foot, or the Somersetshire Regiment, of which he was made serjeant. He served through the whole of the Peninsular campaign, and was in every battle, including the battle of Waterloo. He was at the taking of Monte Video, in South America, and was one of the detachment of the 40th who, under Colonel Henry Thornton, in 1828, were the pioneers of the western district of New South Wales from Sydney to the Blue Mountains. He had the Peninsular and Waterloo medals. He was only once wounded in the whole of his engagements, that being in one of his wrists. As a curious coincidence it may be mentioned that he died on June 18, being the 54th anniversary of the battle of Waterloo.

M. TRONSENS has made a communication to the Paris Academy of Sciences, in which he suggests a new arrangement of ships' lights to prevent collisions at sea. He proposes the use of three lights, arranged in the form of a right-angled triangle, one side of which is to be vertical and another parallel with the medial line of the vessel, and towards the head, and placed in the highest possible position. The light at the summit to be of a different colour from the other two, and the distance between the lights to be about 18ft. Observation of the two lights in a vertical line will, says the author, furnish an approximate notion of the distance from the ship, and by comparing the apparent distance of the two lights on the horizontal side with that of the two on the vertical side, an idea of the ship's route may be obtained; at any rate, the relative distances will show whether that course is to the right or left of the line of observation, which is the main fact to be ascertained, and that without the aid of any instrument being required.

THE following reports from her Majesty's ships "Camel," "Serapis," and "Hercules," on the Wigan Coal Company's Yard coal, have been published:—"Camel": These coals are the most economical coals used for nearly three years; the duties of the engines have been accomplished easier, or otherwise more steam generated than with common Welsh, or a mixture of Newcastle. These coals make very few ashes, and also very few clinkers. There is more smoke, but not as much as from Newcastle; with the exception of Risca Rock coal, they are the best used for fourteen years. "Serapis": This coal is of a good quality for generating steam, but burns more quickly and makes more clinker, soot, and smoke than the several descriptions of Welsh coal generally supplied. It is not suited for the voyages of the Indian troop ships, as it is liable to choke the tubes. "Hercules": This coal is of good quality, little smoke, average amount of clinker and unconsumable ashes, burning fast. Estimated economical value as compared with best Welsh coal—Welsh coal, 100; Wigan coal, 92.

THE annual returns relating to shipping have been presented to the House of Commons, on the motion this session of Mr. Stevenson. They show that at the end of the year 1868, there stood registered at ports of the United Kingdom and Channel Islands, 25,500 sailing vessels of 4,878,233 tons, and 2,944 steam vessels of 902,297 tons; and in the British possessions 11,370 sailing vessels of 1,380,991 tons, and 523 steam vessels of 74,604 tons; making in the whole, 36,870 sailing vessels of 6,259,224 tons, and 3,467 steam vessels of 976,901 tons. If we go back to 1859, as a date sufficiently distant to show the progress of shipping, we find at the end of that year registered at ports of the United Kingdom and Channel Islands, 25,784 sailing vessels of 4,226,355 tons, and 1,918 steam vessels of 436,836 tons; and in the British possessions 10,177 sailing vessels of 961,283 tons, and 321 steam vessels of 35,928 tons; making in the whole 35,961 sailing vessels of 5,187,638 tons, and 2,239 steam vessels of 472,764 tons. The grand totals are these:—In 1859, 38,200 vessels of 5,660,402 tons; and in 1868, 40,337 vessels of 7,236,125 tons.

Miscellanea.

MR. A. JOHNSTON has laid before the House of Commons a Bill to extend to sea crab and lobster fisheries the provisions of the third part of the Sea Fisheries Act of 1868, empowering the Board of Trade to make local orders regulating the fisheries, the inspector of oyster fisheries to be also inspector of sea crab and lobster fisheries.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending June 26, was 3,573. Total number since the opening of the Museum, free daily (May 12, 1858), 1,592,834.

THE borings for rock salt near Wylen, Switzerland, have given very favourable results. Near the Rhine, a bed of 80ft. in thickness has been found at a depth of 420ft. below the surface, and another 50ft. thick not far off. The salt is hard, pure, and of excellent quality.

ON Saturday afternoon, a whale, measuring about 15ft. long, went ashore, alive, at Tynemouth, near the base of the Lighthouse Cliffs. Being observed dodging about the rocks, it was captured by some fishermen, and killed by a soldier sticking his bayonet through it.

The Great Metropolitan Choral Festival of 5,000 voices, to be held at the Royal Horticultural Gardens, under the direction of Mr. G. W. Martin, to-morrow (Saturday), will be the largest gathering of choristers ever brought together for an open air festival. The choir will consist of 3,000 first and second sopranos, 1,000 tenors, and 1,000 basses. The Viceroy of Egypt and several members of the Royal Family are expected to attend the festival.

A SEVERE trial of field implements has recently taken place at Wuren, in connection with the Mecklenburg Agricultural Society. After a series of experiments, lasting two days, our English implements fully sustained their reputation. The first prize bronze medal for wheel ploughs, the first prize silver medal for grubbers, and the first prize bronze medal for jointed harrows, were won by Messrs. Ransomes, Sims, and Head, of Ipswich.

THE number of visitors to the South Kensington Museum during the week ending June 26, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 13,008; Meyrick and other galleries, 2,993; on Wednesday, Thursday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 2,493; Meyrick and other galleries, 310; total, 18,804. Average of corresponding week in former years, 10,911. Total from opening of Museum, 8,553,830.

THE preliminary meeting of the ironmasters of South Staffordshire and East Worcestershire was held at the Exchange in Birmingham, on the 24th ult. A resolution was unanimously passed to adhere to the current scale of prices for all descriptions of manufactured iron the make of this district. At very few of the works are all the mills and forges in full operation, but the trade is unquestionably in a better state than it was three months ago. The quarterly meetings will commence at Wolverhampton on July 7.

WHILE the temperature has lately been almost that of winter, an excessive heat prevails in many parts of Europe. At Kiew, Russia, the thermometer has been as high as 110¾deg. Fah. The rye and wheat are already in ear, and will be ready for harvesting by the end of the month. A drought prevails in Hungary, and the Lake of Neusiedel is quite dry, and the bottom of its bed is covered with thick grass, on which the inhabitants are pasturing their flocks. The heat is so great that fears are entertained of some epidemic disease.

THE forthcoming meeting of the British Association at Exeter promises to be highly attractive to those connected with the mining interests. Advantage has been taken of the proximity of the place of meeting to the mining districts of the Western Counties for arranging a special exhibition of mining products in the Devon and Exeter Albert Memorial Museum. It has been decided that no charge shall be made for exhibition space, and Mr. W. S. M. D'Urban, the curator, has undertaken to furnish all necessary information to intending exhibitors.

THE Japanese dignitaries, says the Boston "Journal of Chemistry," who recently visited this country under the direction of Mr. Burlingame, were observed to use pocket paper instead of pocket handkerchiefs whenever they had occasion to remove perspiration from the forehead, or "blow the nose." The same piece is never used twice, but is thrown away after it is first taken in hand. We should suppose, in time of general catarrh, the whole empire of Japan would be covered with bits of paper blowing about. The paper is quite peculiar, being soft, thin, and very tough.

GENERAL MORIN, in giving an account at the Academie des Sciences of the successful application of his ventilating apparatus in a large weaving factory employing 400 workpeople, and in which were lighted 400 jets of gas, observed that its advantage might be judged of from the fact that during October, November, and December, 1867, when the ventilation was defective, only 15,000 kilogrammes of bread were consumed, while, during the same months of 1868, after it had been improved, 20,000 kilogrammes were required, being a gain of 25 per cent. for the health and vigour of the operatives.

A STATEMENT prepared in the Public Debt Office at Calcutta shows that in the last half of the year 1868 notes of the registered debt of India were presented for interest at the Treasuries of India as follows:—By Europeans, 25,77,74,500rs., and by natives, 11,74,23,300rs. The proportions are 69 per cent. held by Europeans, and 31 per cent. held by natives. These proportions may be assumed to obtain in regard to the whole 57,07,52,600rs., the amount of notes presented and not presented. The enfaced notes held in London, 15,75,19,400rs., are assumed to be held by Europeans.

THE annual Parliamentary return shows that in year 1868, 10,837,804 tons of coal, cinders, and culm, of the declared value of £5,352,525, were exported from the United Kingdom, an increase of 422,026 tons over 1867, but a decrease in declared value. Above 1,900,000 tons were exported to France. 10,575,275 tons were shipped coastways from port to port of the United Kingdom, a less quantity than in 1867 by 724,115 tons. 5,976,452 tons of coal were brought into the port of London in 1868, being 353,098 tons less than in 1867; 2,981,230 tons came coastwise, and 2,995,222 tons by inland navigation and by railway.

THE extension of time granted for the construction of the new dock, with the additional works authorized by the supplemental Hull Dock Act of 1866, expiring on the 28th ult., it was determined by the directors of the Hull Dock Company to virtually open the dock in compliance with the terms of the Act, although the public opening does not take place until the 22nd inst. Accordingly, the Goole steamer "Her Majesty" was placed in the large lock in readiness for the opening of the gates on the arrival of the chairman and directors. The vessel made the circuit of the dock, and returned into the lock pit, from whence, owing to the state of the tide, she was penned into the river Humber.

TOWARDS the close of last week some of the digging claims in the Sutherland goldfields turned out very well, and a few of the lucky diggers made from 10s. to 12s. a day for a few days. This raised the ebbing spirits of most of the men, and all hands are now working with a little more courage. Most of the old claims are running out, and a general desire is expressed that a new allotment of ground should be marked off. A few new hands are still arriving, and the number of licenses issued for the month now amounts to 170. One of the Inverness jewellers visited Kildonan last week, and purchased a considerable quantity of gold at £3 10s. an ounce.

IN carrying out one of the many improvements which the lord of the manor (Mr. Hugh Jones, Bryn Hall), has undertaken in the ancient town of Caerwys, Flintshire, the workmen engaged in pulling down some old masonry a few days ago found imbedded therein some antique and very interesting articles of china and other ware, which must have remained concealed for many generations. Caerwys was a town of great importance during the sovereignty of the native princes, and the present adjoining hall of Maesmynan stands on the site of the palace of that noble chieftain, Llywelyn ein Llyw Olaf, the last independent Prince of Wales. It is expected that curious relics belonging to that period will be discovered in the course of approaching excavations.

A CURIOUS discovery was made at Cracow the other day, during the renovation of the monument of King Casimir the Great, the last member of the Piast dynasty, known in Polish history as "the King of the Peasants and the Jews." One of the workmen having struck the pedestal with his hammer, in order to test its strength, several bricks fell out, leaving an opening through which the interior of the pedestal, which is hollow, was clearly visible. On enlarging the opening it was found that Casimir's coffin, which rested on four iron bars, had rotted away, and that the remains had fallen to the ground. On the skull was a crown of gilt copper, in the shape of a plain circlet surmounted by five lilies. Near this was a silver-gilt sceptre, and close to his feet a pair of large copper spurs. The body was covered with a shroud of thick silk, which is still in tolerably good condition.

RATHER a remarkable circumstance—as showing the strong desire in Turkey to possess railways—is the plan now formed to lay down a railway at the expense of the "vilayet," or Viceroyalty of Broussa. The "Engineer" states that the line is proposed to be between the port of Moudania, on the Sea of Marmora, and the large and busy city of Broussa. This would be executed by money contributions supplied by provincial and municipal taxes, but the earthworks by a contribution of labour, as a labour rate or prestation. The existing roads to Broussa from Ismid and Moudania have proved so useful, notwithstanding all their defects, and the imperfections of the labour rate system, that the inhabitants are encouraged to apply the latter on a larger scale. As a commutation in money is allowed for those who do not work, abuses arise in that department, but, nevertheless, a large fund accrues for construction. When completed, the line will pay well. It is likewise taken up by the Viceroyalty with the view to a possible extension to Konieh in the interior.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3740, 3749, 3762, 3784
BUILDINGS AND BUILDING MATERIALS—3746, 3763, 3772, 3777, 3785, 3788, 3796
CHEMISTRY AND PHOTOGRAPHY—3771, 3785
CULTIVATION OF THE SOIL, including agricultural implements and machines.—3735, 3736, 3755, 3770, 3789, 3790
ELECTRICAL APPARATUS—3780
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3742, 3756, 3758, 3765, 3787, 3794
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3753, 3774, 3775
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—3741, 3757, 3765, 3776, 3782, 3798
GENERAL MACHINERY—3732, 3743, 3779, 3781, 3792
LIGHTING, HEATING, AND VENTILATING—3737, 3750, 3771
METALS, including apparatus for their manufacture—3760, 3785
MISCELLANEOUS—3731, 3748, 3751, 3753, 3759, 3761, 3764, 3767, 3773, 3778, 3780, 3791, 3795, 3799
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3733, 3738, 3744, 3745, 3752, 3754, 3768, 3793, 3800
SHIPS AND BOATS, including their fittings—3747
STEAM ENGINES—3783
WARFARE—3734, 3769, 3797

3731 F. A. FARWIG, Selurst, and C. HAYNES, Bermondsey New-road. *Sheet metal casks.* Dated December 8, 1868.

The inventors make metal casks with four equal sides, the heads and bottoms having flanges, which heads and bottoms are placed in their positions inside the body of the casks, then dipped or soldered and riveted in the ordinary way. The body is made in four equal parts, bent at right angles and joined together with the usual lap-jointed double seams in centres. The top of the cask is made concave and convex, for the purpose of strengthening the top of the cask, and the concave forms an air chamber. The body and bottom are made with convex or hollow flutes, and when extra strength is required that is produced by soldering or fastening to the inside of the cask tinned wire or other metallic ribs.—Patent completed.

3732 J. FITTER, Birmingham. *Nuts.* Dated December 8, 1868.

This consists, first, in making the nuts or screw boxes of table expanders of a white metal or alloy, in place of the bars or gun metal ordinarily employed for that purpose. The nuts or screw boxes are made of this white metal or alloy by the process of casting. Second, in casting the nuts or screw boxes of table expanders on the screws of the table expanders by the use of metal moulds instead of casting the nuts or screw boxes in sand, as is usually practised.—Patent completed.

3733 O. REYNOLDS, Manchester. *Signalling.* Dated December 8, 1868.

This consists, principally, in attaching some suitable explosive material or compound to any convenient part or parts of the train, such explosive material or compound being so attached and connected with a trigger button, ring, or other suitable contrivance, that it may be exploded by any of the passengers or by the guard when necessary, and by its report convey the required signal to the guard or engine driver.—Patent abandoned.

3734 R. B. RODEN, Usk. *Firearms.* Dated December 8, 1868.

The ordinary lock which usually is placed upon the side of the stock, or in some instances in the centre of the stock, is by this invention entirely dispensed with, and the piston or striker by which the ignition of the cartridge is effected is operated or functioned by a lock in connection with, attached to, or formed partly in, the breech lock or closer, and in some instances moving with and on the same axis as the breech lock, and, if required, securing or locking the breech block firmly in position during the discharge of the cartridge. The breech block or closer and shoe or barrel, where no shoe is employed, together with the trigger arrangements and mode of latching down the breech block or the piston of the latching stud, and the manner of attaching the shoe or barrel to the stock, as also the form of the stock itself, may be varied and modified to suit the altered requirements.—Patent completed.

3735 T. SPEIR, Blackstone. *Cultivating land.* Dated December 8, 1868.

This consists in fixing one or more pairs of plough shares, mould boards, and bodies to brackets fitted on opposite sides of a shaft. This shaft is carried in a rectangular frame, and when the machinery or apparatus is in operation, the shaft lies in a diagonal direction. When the ploughing mechanism or apparatus has travelled across the field which is being ploughed or cultivated in one direction, the position of the diagonal shaft is reversed, and at the same time turned upon its axis so as to turn the plough bodies (which are fixed on the opposite side of the shaft and point in an opposite direction) into position to enable the apparatus to be employed in cultivating or ploughing the land in a reverse direction.—Patent completed.

3736 T. SPEIR, Blackstone. *Cultivating land.* Dated December 8, 1868.

This consists in placing one or more pairs of plough shares, mould boards, and bodies upon a series of transverse shafts carried upon an oblong frame. The plough shares, mould boards, and bodies are fixed on opposite sides of the shafts, an equal number being placed on each side so as to cut an equal number of furrows in advancing or returning across a field. On each of the transverse shafts a pitch or chain wheel is fitted, actuated by a pitch chain or an ordinary chain from the central transverse shaft, which may be fitted with a double pitch or chain wheel, so as to actuate the transverse shafts, which are situated on each side of it by separate chains, or an endless chain may be used for that purpose. By means of a hand wheel the shafts are turned on arriving at each side of the field being cultivated, so as to bring the proper set of ploughs into position, according to the direction in which the apparatus is to travel.—Patent completed.

3737 F. LANCASTER, Bootle. *Consumption of fuel.* Dated December 8, 1868.

This consists in placing or building within, and at a short distance from the back end of the furnace, a firebox or other fire grate. A metal plate, or a metal plate and firebrick, firetile, or fireclay combined, in some cases perforated with holes for the admission of air from the chamber formed by the space left between the plate or wall, or both of them, and the tube plate or back of the furnace. This chamber has an inlet for the admission of atmospheric air proportioned to the quantity of air, which in each particular case may require to be admitted. The inlet opens under the firegrate, and is furnished with a regulator in the form of a damper, door louvres, or other suitable mechanical arrangement, and is worked from the front of the furnace in any convenient manner inside the firebox, furnace, or other firegrate.—Patent completed.

3738 F. W. MOSS and G. MOSS, Leicester. *Railways.* Dated December 8, 1868.

In carrying out this invention, the inventors dispose between the rails of a line of railway, projections, in the shape of double inclined planes, placed at suitable distances apart. Each of these double inclined planes is made to slide transversely in a guide placed between the line of rails by means of a chain or wire attached to each side of the inclined planes. Each of these chains is connected to a bell crank placed at opposite sides of the line. One of these bell crank levers communicate by means of a chain or wire with a bent lever or other device pivoted at one side of the line, a short distance in advance of the inclined projection, in such manner that it will be on a level with or above the rail, near which it is placed, so as to be depressed by one of the wheels of the engine when passing.—Patent abandoned.

3740 C. P. COTTON and J. L. LYSTER, Dublin. *Kilns.* Dated December 8, 1868.

In a kiln constructed according to this invention, the upper part of the chamber of the kiln may be of any usual shape—elliptical, cylindrical, conical, or otherwise. At a certain point, say, about one-third the entire height of the kiln from the bottom, the chamber suddenly expands below this point, and from this expanded portion it becomes gradually narrower down to the draw hole or bars.—Patent abandoned.

3741 W. H. POTTLE, Gray's Inn-road. *Umbrellas, &c.* Dated December 8, 1868.

This relates to the runners of umbrellas, parasols, and sunshades, and arrangements in connection therewith. The improved runner is formed with a longitudinal slot or opening, and is fitted or provided with a ring or collar, which is capable of being rotated or turned on the runner wholly or partially, that is to say, to the required extent in both directions. Suitable stop arrangements are provided to hold the ring in the required position. A portion of this ring is raised or arched, so as to form a sort of bridge-piece. Two pins, studs, or stops are fixed in the stick, one at the upper and the other at the lower part thereof, in convenient positions for the operation of the runner.—Patent completed.

3742 J. KIRK and J. KIRK, Nottingham. *Weaving.* Dated December 8, 1868.

The inventors place between every carriage thread used (emanating, of course, from the bobbin encircled within the carriage) in that part of the fabric to be woven any given number of longitudinal warp threads, ranging in number according to the closeness of the weaving desired to be produced. The warp threads are caused to move in such manner that each bobbin thread produces a portion of the weaving. These warp threads are all weighted, so as to draw off any required quantity of the bobbin or wefting threads, according to the distance or number of longitudinal warp threads over which they should be drawn.—Patent completed.

3743 J. BALL, Nottingham. *Cutting threads.* Dated December 8, 1868.

There are two standards, one at each end of the machine. Each standard has three vertical arms; the standards are connected by tie bars near the lower part. The front vertical arms of the standards are also connected at their upper ends by a tie bar; the tops of the back arms are also connected by a tie bar. The upper ends of the central vertical arms are connected by a tie bar, which is formed with a knife edge on the top side and in front of the last-mentioned tie bar, but is placed somewhat lower in another bar, which has a rounded smooth edge on the top side. This bar is also secured to the front of the central vertical arms, and below the last-mentioned bar.—Patent abandoned.

3744 G. P. WHITE, Furnival's-inn. *Roadways, &c.* Dated December 8, 1868.

The inventor employs corrugated wrought iron or steel plates, riveted together to the required width, laid with the corrugations extending across the roadway or platform from side to side. The corrugated plates are curved or arched upwards to the contour of the roadway, which is laid directly upon them, and at either side of the roadway or platform their edges are supported by angle irons, which are tied together by the tie bars of T iron, or iron of other form, or transverse girders passing from one angle iron to the other underneath the corrugated arch. Longitudinal bearers or supports, which may advantageously be of timber, so as to avoid a too great rigidity, are introduced between the arched plates and the ties.—Patent completed.

3745 W. BAINES, Smethwick. *Signalling.* Dated December 8, 1868.

For signalling and working the switches, in order that it may be impossible to place the signals in a manner inconsistent with the position of the switches, and therefore dangerous, the inventor fixes to the lever of the trailing points a long socket or boss, on which the other levers of the switches and signals are mounted and turn. The socket or boss carries a bar running from end to end of

it. This bar, which acts as a stop, passes through slots in the signal levers, and also in the lever of the facing points, in order that the facing point lever may control the positions of the down signal levers. These are mounted on each side of it, and between them and the facing point lever there are mounted frames or plates, capable of sliding a short distance in guides in a direction at right angles to the plane in which the point lever moves. There are notches in the frames or plates, which fit projections on the levers, so as to hold the levers.—Patent completed.

3746 S. S. ANDERSON, Bishops Auckland. *Bricks, tiles, &c.* Dated December 9, 1868.

This consists, first, in the application of a steam cylinder for the purpose of imparting a reciprocating motion to the cutter frame of that class of brick and tile-making machines where the clay or other plastic substance is moved forward through a suitable die on to the cutter table by means of screw blades turning upon a central axis in a mixing chamber. The slide valve of this steam cylinder is worked by means of studs or a cam fixed upon the axis of the roller, which conveys the clay or other plastic substance from the die box on to the table upon which it is to be cut into bricks, tiles, or other similarly shaped articles. Second, in an improved die box with a chamber for containing the lubricating fluid, attached thereto and fitted with suitable plugs, taps, or valves for regulating the supply of lubricating material to the inner surface of the die.—Patent completed.

3747 J. T. PARLOUR, Brooklyn, New York. *Blocks.* Dated December 9, 1868.

This relates to keel and bilge blocks, which are more especially designed for supporting a ship or other vessel laid up in dock for repairs. These blocks are made in several parts or sections, and the invention consists chiefly in the peculiar construction and arrangement of the parts or sections, and in the novel means for adjusting and securing the same in any desired position under the vessel to adapt the blocks to vessels of various dimensions without removing the water from the dock.—Patent completed.

3748 F. MEADOWS, Red Lion-court. *Brass ruling.* Dated December 9, 1868.

In machines constructed according to this invention, the knife or cutter is fitted in a carrier, free to be moved up and down in vertical guides. A link, operated by a lever handle, bears upon an incline on the carrier. The carrier carries a platten or presser fitted in a vertical guide therein, and a strong spring on the carrier presses on the platten.—Patent completed.

3749 R. NEEDHAM, Dukinfield. *Fuel economizers.* Dated December 9, 1868.

This relates, first, to the means of driving the gearing which gives motion to the scrapers of fuel economizers, and consists in obtaining the necessary motion for this purpose from the force of the feed water as it is fed into the economizer. This may be accomplished in various ways; for instance, the water might be made to raise a clack valve, the motion of which is communicated to a ratchet wheel by means of a catch and lever and clack valve, which rises and falls as the feed water is forced through the pipe, and thus acts on the lever, which is connected by means of the connecting rod to the ratchet lever.—Patent completed.

3750 J. BOLTON, Bristol. *Charcoal.* Dated December 9, 1868.

The inventor makes the retorts conical, and mounts them with their axes horizontal. By this the charcoal is carried forward continuously by the simple revolution of the retort without internal mechanism. He also, in some cases, makes the retorts with corrugations lengthways, by which means a much larger amount of metallic heating surface is obtained, and the charcoal, which is itself a bad conductor of heat, is consequently more uniformly heated. In some cases, in order to increase the heating surface, he places inside an otherwise plain retort a number of ribs or shelves running lengthways of the retort and radiating from the centre; such ribs also give increased strength to the retort.—Patent abandoned.

3751 J. PARKINS, Brewer-street, Golden-square. *Embossing, &c.* Dated December 9, 1868.

The machine consists of an oblong metal frame fixed at one end to an ordinary stamping machine bevelled off on its inner edges so as to form V guides on which the die bed slides. This die bed consists of a steel or other metal block having a hole in it for the reception of the die. A small trough is attached to the inner side of the die bed, to catch the superfluous ink that will be caused to flow round and down the die by the sharp edge of the die coming in contact with the brush of the inking apparatus. Sliding on this oblong frame is another and smaller metal frame which receives a reciprocating or forward and backward motion from the die bed, which is actuated by means of cords acted upon by a treadle and weight, or by any other suitable mechanical arrangement. On the sides of this second frame are formed vertical wedge-shaped cams, which, as the frame and die bed are moved to the right, in order to bring the die under the inking brush, will support the cushion or impression frame out of the way so that the die may pass forward without touching it.—Patent completed.

3752 T. STURGEON, Manchester. *Signalling.* Dated December 9, 1868.

This consists in an improvement upon the ordinary vibrating electric bell. Besides making the usual connections between the belt and the battery, the inventor makes another connection by means of a wire passing through these points, from which it is desired to have a means of communication.—Patent abandoned.

3753 A. G. GOODES, Newgate-street. *Cigars.* Dated December 9, 1868.

The inventor employs the husk of the Indian corn or maize plant (Zea mays) to form the "bunch" wrapper instead of using either paper or tobacco for this purpose. The flavour of the cigar or cheroot will in this manner be greatly improved. The husk is applied in its natural sun-dried condition for wrapping round the "bunch," in the same way as when using tobacco leaf or paper for the purpose.—Patent completed.

3754 W. GRIFFITHS, Mount-street, Grosvenor-square. *Bits and bridles.* Dated December 10, 1868.

The inventor provides each end of the bit bar, in addition to the ordinary rings to which the reins are attached, with another smaller ring through which the safety reins are to be passed, the bit bar being made either in one piece or jointed in the centre.—Patent completed.

3755 J. NORMAN, Glasgow. *Grinding grain.* Dated December 10, 1868.

This comprises two serrated plates, between which the grain passes, whilst one plate has imparted to it, by means of a revolving crank or its equivalent, a short rapid reciprocating stroke, or both plates may be made to reciprocate in different directions.—Patent completed.

3756 W. H. PLATT, Ashton-under-Lyne. *Shuttles.* Dated December 20, 1868.

The object is to dispense with the square mortise hole which is usually made in the lower side of the shuttle. Instead of cutting the square mortise hole beneath the shuttle for the reception of the spring, the inventor only mortises away sufficient from the upper part of the shuttle to receive the square end of the shuttle peg, and from the base of this short mortise he bores out a hole in the direction of the shuttle point, and he inserts therein a straight or flat spring, slightly curved or bent at one end, supporting and holding the said spring by means of two pins or cotters driven in from the side of the shuttle.—Patent abandoned.

3757 W. G. MANWARING, Banbury. *Sewing machines.* Dated December 10, 1868.

This relates to lock-stitch sewing machines, wherein the needle is actuated from a rotary driving shaft or spindle carried in the fixed arm of the machine, and consists essentially in transmitting motion from the overhead shaft to an oscillating or vibrating shuttle carrier, by means of an eccentric crank pin, cam or other mechanical equivalent mounted on the driving shaft, and connected by a connecting rod and short lever arm with a rocking shaft situate below the cloth plate, which rocking shaft carries the vibrating shuttle drum.—Patent abandoned.

3758 A. MATTHIESEN, St. Bartholomew's Hospital. *Paper.* Dated December 10, 1868.

The inventor submits wood when in a state of division, such as shavings, sawdust, or disintegrated wood, to what is known as a retting process, that is to say, the wood in a state of division is steeped either in running or stagnant water, and is allowed to undergo a retting or fermenting process, by which process certain constituents of the wood will be decomposed and removed, and the subsequent treatment of the residual ligneous fibre for the production of pulp or paper will be thereby rendered more economical, and the process of boiling and bleaching be more easily effected.—Patent completed.

3759 H. A. BONNEVILLE, Paris. *Measuring.* (A communication). Dated December 10, 1868.

This consists in a graduated circle, giving, by means of a vernier, the ten seconds of horizontal angles. There is a glass moving in the plane perpendicular to the circle, and another glass fixed by a support in the vertical plane of the glass upon the circle. A powerful microscope is closely connected with the glass, and there is a very sensitive level resting on a ruler of a determinate length. A scale is fixed vertically at the extremity of the ruler, in the plane of the optic axis of the microscope, and divided into half millimetres (the millimetres are alone marked with a figure comprised between 1 and 100). A micrometrical screw is joined to the lower part of the scale, giving the 2-10,000th of a millimetre of the scale read on the graduated circle of the screw. Another very sensitive level may be applied on the glass, and serves to determine its horizontal position.—Patent completed.

3760 W. GRAY and T. BIGGIN, Sheffield. *Spanners and wrenches.* Dated December 10, 1868.

This consists, first, in the placing of the cavity in the moulds to receive the steel in a fluid state in a slanting direction, so that the stream of molten steel, when poured into the moulds, falls straight to the bottom of the mould, as shown, so as to keep clear, and not come into contact with the movable or fast steel pegs or cores, which would be liable to be damaged by the molten steel falling upon them, and also prove injurious to the articles produced. The moulds are proposed to be made in parts or portions, to open with or without a hinge at the bottom, as may be found most convenient.—Patent completed.

3761 W. S. JACKSON, Carter-street, Walworth. *Decomposing bones.* Dated December 10, 1868.

This consists, first, in a more effective and economical method of applying solutions of hydrochloric acid and similar known solvents to bones, for the purpose of dissolving the earthy matter, and separating it from the animal matter thereof, by arranging the bones in suitable vessels, as described herein, and then subjecting them to the solvent action of the solutions, these solutions being applied to the bones under an increased pressure or at the ordinary atmospheric pressure only as required, until they are saturated, or nearly so, with the earthy matter of the bones. Second, in the decomposition of the phosphates of calcium, obtained by the action of solutions of hydrochloric acid or bones, by means of silicic acid, for the economical extraction of their phosphoric acid and phosphorus. Third, in submitting the animal matter obtained by the action of solutions of hydrochloric acid or bones to the direct action of high pressure steam for the productions of gelatin and glue.—Patent completed.

3762 J. SMITH, Kingsland, and J. F. N. B. SIMONS, Great St. Helens. *Steam boilers.* Dated December 10, 1868.

The boiler is completely encased in brickwork or setting, with the exception of the top of the steam dome and the manhole cover. This brickwork or setting is not in contact with the boiler, but an air space an inch or so wide is left. This space is in communication with the flues, so that the air in the space becomes heated, and there is no outlet from the casing, so that the draught is prevented passing through it; otherwise, the boiler would become unduly heated over the water line.—Patent abandoned.

3763 C. E. BROOMAN, Fleet-street. *Roofing.* (A communication). Dated December 10, 1868.

This consists in roofing or covering houses or other buildings with oblique slates or tiles secured by bent metallic wires or fastenings and staples or eyes on wooden or metallic lathwork. To carry out this mode of roofing, square slates or tiles are employed without a shoulder, and with a notch at the base to receive the metallic wires or fastenings fixed to oblique lathwork. The wires or fastenings are preferably of zinc or of galvanized iron. The bottom or lower part of each engages into the notch of a slate or tile, whereby a strong roof or covering is obtained.—Patent completed.

3764 J. F. BENTLEY, Peterborough. *Wells.* Dated December 10, 1868.

This relates primarily to sinking or forming wells by the employment of cylinders with conical ends which are caused to enter into finely divided silica or other kinds of earthy matter commonly called "silt," "quick silt, &c."—Patent completed.

3765 W. DAWES and E. A. RAMSDEN, Leeds. *Harmoniums, &c.* Dated December 10, 1868.

Upon or in connection with the pallets or valves of the "Bourbon" or other bass notes of the instrument, or in some cases upon additional reeds for this purpose, the inventors use reverse-action levers or other suitable or convenient mechanical movement or attachment, so constructed that the pressing down of any key within the range or limits of the attachment shall silence or prevent the speaking of all the notes above itself in the stop or stops thus fitted, and shall restore or allow the speaking of any note above itself when it is lifted or ceases to be the sub-bass note required, so that when in action the stop or stops to which this automatous movemen its applied can only speak or sound "one note at a time," and that the lowest note that is pressed down or used by the player upon the keys instead of the highest or upper note.—Patent completed.

3766 J. PICKLES, E. RAMSBOTTOM, S. HAGGAS, S. FOULDS, J. SHACKLETON, all of Bingley, York, and W. BERRY Bradford *Spinning frames.* Dated December 11, 1868.

Upon a small portion of the spindle top the inventors form a double threaded (or it may be a treble or quadruple threaded) screw, with a plain part above and below it. The flyer has a corresponding female screw tapped into the upper part of the head or boss thereof, the lower part being plain to correspond with the plain part below the screw on the spindle top before mentioned. This screw, which is made left handed, as usual for the spindles of spinning frames, and right handed for twisting frames, greatly accelerates the disconnection of the flyer from the spindle. They make the pitch of the screw from ¼in. to ½in., and so that by giving a slight touch to the shoulder of the flyer in the direction the spindle runs, it will release itself from the spindle in one turn of the screw, or thereabouts.—Patent completed.

3767 R. WAYGOOD, Newington. *Ventilation of mines.* Dated December 11, 1868.

This consists in fitting or constructing self-acting valves in the ventilating shaft, and in the approaches from the workings thereto. These valves open to allow of the ordinary upward current, but immediately close against any tendency to a return current. The valves may consist of strong sashes divided into squares, each of which is provided with a hinged balanced flap opening outwards only.—Patent abandoned.

3768 T. HOLDER, Westbourne-road, and G. DOVER, Holloway. *Horse shoes.* Dated December 11, 1868.

This consists in adapting a clip-shaped piece of metal or appliance to the front part of a horse shoe when fixed to a horse's foot by nails in the usual way; also in placing roughing pieces or points of steel loosely in such said clip piece, so that they can only be removed or withdrawn when the clip is taken off or removed from the shoe when the roughing points are worn down or otherwise rendered useless.—Patent completed.

3769 H. CARTER and G. H. EDWARDS, Bow. *Firearms.* Dated December 11, 1868.

The breechblock or plug is arranged to open and close by a vertical motion by means of a hinge or joint in connection with the barrel, the plug fitting the space cut away in a converted gun, or falling into the space formed in a gun manufactured in the first instance for a breech-loader. The under surface of the plug is flat at the sides to fit the upper surfaces of the sides of the open breech, and is provided at each end with a slotted guide, the guide nearest the barrel serving to contain the striking pin, the stop of the same, and a tube to which it is connected, the other guide containing the sliding locking catch, whereby the plug is shut down and secured in the body of the gun. This locking catch protrudes or extends beyond the closing end of the plug, and retreats when in the act of closing, by reason of the angular or curvilinear face against the surface of the rear of the body. It is also in line with a stem which enters the tube on which the stop of the striking pin is fixed, and a spring being inserted within the tube it follows that the action of the closing catch and tube, stop, and striker, will always be antagonistic, the spring tending to drive the respective parts from each other.—Patent abandoned.

3770 P. KOTZO, Pesth, Hungary. *Reaping.* Dated December 11, 1868.

The object is to ensure the efficient working of the rakes and gathering arms of reaping machines by the use of a simple construction of driving gear. This the inventor proposes to obtain by the employment of an inclined rake shaft, which when rotated will give the desired rising and falling movements to the rakes and gathering arms, and cause the latter to come into contact with the corn and gather it up to the knives, and when the corn is cut enable the rakes to sweep the corn off the platform on to the ground.—Patent completed.

3771 W. H. BAILEY, Salford. *Regulating heat.* Dated December 11, 1868.

In pyrometers where the indication of the temperature depends upon the expansion of rods or tubes of different substances it is sometimes necessary to adjust the indicating apparatus so as to compensate for the permanent expansion which may have taken place in either of the substances used. This invention consists, in the first place, in arranging pyrometers so that this adjustment may be made without taking any part to pieces. This is accomplished as follows:—The indications are made in the usual way by means of a hand or pointer working over a graduated dial, but instead of attaching the case which carries the dial permanently in one fixed position upon the tube or rod, it is screwed on up to the proper position, and secured by means of a small stud which passes through a slot and holds it just sufficiently tight to prevent it being moved by accident. This slot is long enough to allow of the dial being screwed up after the substance has been permanently expanded sufficiently far to maintain the relative lengths of the bars and compensate for the permanent expansion.—Patent completed.

3772 F. WALTON, Staines. *Building.* Dated December 11, 1868.

The inventor constructs a light building requiring only comparatively unskilled labour in its erection and but little foundation, and which is very dry and warm, in the following manner:—He takes a number of narrow planks and places them horizontally one over the other, separating them one from the other by placing at intervals blocks or short uprights between them. These blocks may be of

wood or a moulded brick or drainpipe. In this way, a frame of the desired dimensions is produced, the blocks being arranged in vertical lines, and the frame being firmly bound together by long bolts passing from top to bottom of it. Each bolt is passed close alongside of, or it may be through, a vertical line of blocks. The frame may be lathed and plastered on both sides, or wicker-work hurdles may be fixed upon it to receive the plaster, or it may be planked or otherwise closed. In place of wood planks and blocks, other materials may, in some localities, be advantageously substituted; thus, for the planks, sheet iron bent to a trough-like form or otherwise may be used, and for the blocks lengths of iron tube may be substituted. The inventor takes a number of iron bars or sheets, about ½in. to ¼in. thick, the edges of which are turned up by a pair of rollers, and the patentee places them horizontally one over the other, separating them from each other by placing short cast-iron pipes or tubes between. The pipes are arranged vertically one over the other, and either through or alongside of each vertical line of tubes a long bolt is passed through all the sheets of iron, and screwed up tight. A rib or bar of wood is then bolted on to the flanged edge of the iron sheets, and then the frame so constructed can be lathed and plastered, or it can be covered with iron, wood, or felt. When plaster is used, wickerwork hurdles or wire gauze may be used instead of laths to receive the plaster. Blocks of concrete, with holes through them, or earthenware tiles or blocks of wood may be substituted for the cast-iron tubes aforementioned.—Patent completed.

3773 E. H. BAYLEY, Newington-causeway. *Filters.* Dated December 12, 1868.

Instead of one sediment well, three wells of a cylindrical form are placed transversely across the bottom of the tank. The water in the tank flows first into the central well, to the bottom of which the sediment falls through a trap, and is drawn off by a cock. The water thus partially purified then flows through two separate pipes into the lower part of the two outer wells.—Patent completed.

3774 B. HUNT, Searle-street. *Cooking.* (A communication). Dated December 12, 1868.

The apparatus in question is composed principally of five tubular boilers, constructed as to their details in accordance with the French patent of Mr. Cail, dated May 23, 1860 (No. 45,242). Besides the five boilers, it is provided above and below with an injection or a surface condenser, or with condensers of another kind.—Patent completed.

3775 J. MILLWARD, Birmingham. *Preserving meat.* (A communication). Dated December 12, 1868.

This consists in subjecting the meat or animal matter to be preserved to the following process or method of treatment:—The meat, either in whole carcases or in parts, is suspended within a vat or receiver, from which the air is then exhausted as completely as practicable by an air pump or other means. The vat is then rapidly filled with gaseous bisulphide of carbon, protosulphide of carbon, carbonylic sulphide, or some equivalent gas, either alone or with phenic acid, methyl, or other product of the destructive distillation of wood or coal. The sulphides of carbon may be produced by any of the well-known methods. When such phenic acid or methyl is used, it is employed in the proportion of about one ounce thereof to every 100 cubic feet of sulphide of carbon gas, but the inventor does not limit himself to these proportions, and the phenic acid or methyl may be dispensed with entirely. —Patent completed.

3776 A. WOODS, Holloway. *Spring mattresses.* Dated December 12, 1868.

The inventor takes, by preference, three frames, and places one above the other. The top and bottom frames are made of the same size, and are adapted to the shape and size of the bedstead to which they are to be applied. The third frame, and which is placed between the top and bottom frame, is somewhat smaller than the others, and the patentee makes the frames of wood, and, by preference, of spruce, deal, or pine, for the sake of lightness. —Patent completed.

3777 H. LAW, Essex-street, Strand. *Waterclosets.* Dated December 12, 1868.

The inventor connects the service pipe, by means of which water is to be supplied to the closet, whether from a main under pressure or from an elevated cistern, with a valve cock so constructed that upon raising the piston of the same, communication is opened between the service pipe, and a vessel of vulcanized india-rubber or other suitable elastic material, capable of expanding under pressure and of contracting upon the removal of the same, and he encloses this vessel with a mould of the size and form which it is desired that the vessel should assume when filled with water under pressure, and of sufficient strength to resist the greatest pressure to which the vessel can be exposed.—Patent abandoned.

3778 C. ELLISON and E. PARKINSON, Crosshills. *Measuring.* Dated December 12, 1868.

This consists of a stand in form of a cross, the stem or upright being in two or more parts, so as to be adjustable in the height of the crosspiece to the armpit or under the arm of the person to be measured, the bottom of the stand resting on the ground or floor. The crosspiece is flexible, and with a strap having eyelet holes attached to one and with a stud or pin in the other, so that it may be bent around and secured to the body. An upright piece is attached to the cross so as to be adjustable to the centre of the back, and also to the height of the back of the neck or collar. On this upright are two other parts at right angles thereto, one capable of being set to the back of the shoulder and the other to the waist of the person being measured. On the other arm of the crosspiece is an upright, capable of being set or adjusted thereon, and to the front of the neck of the person, and also on the said cross are two adjustable bosses or collars, to which are attached tape measures, to measure the shoulder and waist. On the lower part of the stem is also an adjustable crosspiece to lay across the thighs, on which is a boss carrying a plummet line and an upright piece to adjust to the front centre of the body on which is a crosspiece to adjust the fork or between the thighs of the person.—Patent completed.

3779 T. SMITH, Birmingham. *Bellows.* Dated December 12, 1868.

This consists in securing a pair of guide rods in a horizontal position in the body of the bellows from front to back, the forward ends of which are attached to an annular collar forming part of the body. The other ends of the guide rods are secured to the bottom of the bellows. The larger end of the pipe is formed with a suitable flange or collar, and slides upon the pair of guide rods through the annular collar into the body of the bellows. When the pipe is required to be fixed in position, it is drawn out upon the guide rods, and secured by screws or bolts passing through the annular collar and the flange or collar of the pipe.—Patent abandoned.

3780 Z. POIRIER, Lambeth. *Stoppers.* Dated December 12, 1868.

This safety stopper is composed of a short vulcanized india-rubber or cork tube, in the upper part of which is inserted a metallic ring, on which this tube is kept fast by any suitable means, either by binding, spurs, expansion, &c. A screw-tapped peg with a conical head is inserted upwards in the india-rubber tube, through which it runs, and is provided with a round screw nut at its upper part. This tube so fitted is inserted in the neck of the bottle to be stopped, and the screw nut being turned to the right with the fingers causes the screw-tapped peg to move upwards; the conical head of the latter entering gradually in the india-rubber tube presses it against the internal side of the neck at the very place where this neck is conical, and the bottle is hermetically closed, because the conical head of the peg presses the india-rubber or cork tube in its whole periphery against the conical neck of the bottle. To open the bottle, the screw nut must be turned to the left; then, by pushing down the peg, its conical head comes out of the rubber tube, and the stopper is easily removed.—Patent completed.

3781 S. COPPERTHWAITE, Chapel Allerton, York. *Turning.* Dated December 12, 1868.

This consists of apparatus to be applied to an ordinary lathe, in which apparatus a series of cutters is so arranged in a drum that, as it revolves, each cutter is successively caused to act on the material or blank to be turned, so that the shape of the said blank is perfected during one revolution of the drum.—Patent abandoned.

3782 C. E. BROOMAN, Fleet-street. *Indicators.* (A communication). Dated December 12, 1868.

The apparatus, when applied to letter boxes, comprises two turning prisms, one of which, for carrying the figures to show the hours or times of collection, has a vertical axis, and the other, for showing the days of the week, has a horizontal axis.—Patent completed.

3783 G. PRESTON and J. PRESTIGE, Deptford. *Lubricators.* Dated December 12, 1868.

This relates to lubricators for the use of tallow and other hard fatty substances. The process of lubrication with the lubricators is continuous, and by means of an internal spiral tube or worm becomes operative immediately the steam is admitted to the engines.—Patent completed.

3784 J. ERSKINE, Manchester. *Economising fuel.* Dated December 12, 1868.

This consists in forming the fire-bridge on a beam or otherwise, to commence about on a level with the fire-bars, and ascend to within a few inches of the under side of the boiler or top of the flue or furnace.—Patent abandoned.

3785 J. HAMILTON and J. B. CRAWFORD, Glasgow. *Cutting stone, &c.* Dated December 12, 1868.

This consists in using a thin blade of steel which is held in a suitable tool holder, attached to or forming part of a planing or slotting machine slide rest or revolving disc. The thin blade of steel is placed in a groove or recess made to receive it in the front part of the holder, and at the lower or cutting end it is supported by a piece of metal projecting downwards from the holder, so that as the cutting action is going on, the projection affords a rigid bearing to the tool. The tool holder is provided with a screw rack and pinion rollers, or other means for lowering the tool as its lower end wears away, or it may be lowered by the attendant workman.—Patent abandoned.

3786 A. PRINCE, Trafalgar-square. *Reducing ores.* (A communication). Dated December 12, 1868.

The ore of gold or silver is to be powdered and mixed with a proportionate quantity of fluoride of calcium, natural or such as is artificially prepared, or of any other fluorine salt or acid, and the mixture is to be exposed to the combined action of steam and carbonic acid. A decomposition of the mineral results, and a milky solution is obtained, from which the mechanically suspended gold is abstracted, by passing the liquid through a bath of mercury or other suitable menstrum. The refuse of the mineral solution is used as a cementing liquid or base for paint.—Patent abandoned.

3787 G. A. C. BREMME, Liverpool, *Flax.* Dated December 12, 1868.

This relates to new and improved apparatus for causing the continuous rotary movement in one direction of a shaft or prime mover to communicate to other parts of the mechanism a reciprocating rotary movement greater in the one direction than in the other, and such improved apparatus is especially applicable to the machinery referred to above. The construction which is adopted for this purpose is the following:—A toothed wheel is fixed on the reciprocating shaft of the roller, and a pinion is held in gear with this wheel, by means of radii or arms, connecting the axis of the wheel with the axis of the pinion, allowing both to rotate freely, but keeping their axes always at the proper distance for gearing. The axis of the pinion or any convenient point of the arms or rocking frame is connected by a connecting rod to a crank or eccentric, fixed on a continuously rotating shaft or prime mover, so that as this prime mover rotates, the pinion is caused to vibrate in an arc described from the centre of the reciprocating shaft. On the reciprocating shaft he mounts loosely a pulley or wheel which is driven with continuous rotary motion by a band, strap or by suitable gearing from any convenient prime mover. This pulley or wheel has affixed to it a toothed wheel or pinion, which gears into the vibrating pinion or into a wheel affixed to it.—Patent completed.

3788 H. L. D. MARSDEN, Louth. *Framings and joints.* Dated December 12, 1868.

The transverse section of the parts to be jointed together may be either three or four sides, or polygonal or circular, but the inventor prefers the square form. The construction of the joint or a portion of the frame is as follows:—Taking timbers of square transverse section as an example, namely, two pieces are placed across each other and in contact, and are then bolted, screwed, pinned, nailed, or otherwise rigidly fastened together; a third piece is then placed in one of the angles formed by the intersection of the first two pieces, having parts of two of its sides in close contact with a portion of a side of each of the two first pieces. The direction of the length of the third piece must be inclined to the direction of the length of each of the other two, and not be parallel with it. Parts of the other forms are united in a similar manner.—Patent abandoned.

3789 J. HINE, Cockermouth. *Millstones.* Dated December 12, 1868.

The apparatus consists of a rectangular frame having a longitudinal opening or slot, in which works the block containing the diamond or other cutter. This frame is firmly attached, by means of a nut working in a slot at one end of the frame, to a radial arm pivoted at the centre of the millstones, so as to turn freely, the pivot being fixed to an adjustable plate fitting in the eye of the stone. The attachment between the arm and frame is adjusted by means of the nut and slot, so that lines may be cut tangentially to any circle described from the centre of the stone. When a line has been cut by traversing the cutting tool or block by hand from one end to the other of the opening in the frame, the frame is advanced a suitable distance for making a second cut by turning a thumb screw connected to and placed in the rear and near the outer end of the frame. The thumb screw works in a screw socket pivoted to a bed plate, resting on the stone on which the operator sits. In this manner, by turning the thumb screw each time the cutting block traverses the frame, a number of similar and successive cuts will be produced, extending from the circumference of the stone tangentially to any circle described from the centre of the stone, according to the angle at which the radial arm is fixed to the frame. When the thumb screw has reached the end of its course, the motion is reversed, and the bed plate advanced, to proceed as before, until the cutting or dressing of the stone is completed.—Patent completed.

3790 R. NORFOLK, Beverley. *Reaping.* Dated December 14, 1868.

This consists in performing these operations by self-acting machinery, actuated from the driving wheel or other convenient part of the machine, whereby not only is the labour reduced, but the work is performed with more regularity than heretofore. A convenient mode of carrying out this invention is as follows:—To the driving wheel or its axle is fixed a toothed wheel gearing into another wheel, to which is attached a cam which acts on a lever projecting from the platform. The cam is made with a long dwell to hold the platform up, while the corn is accumulating upon it, and with a recess to allow the platform to drop suddenly when a sufficient quantity of corn for making a sheaf has been cut. The toothed wheels above referred to can be changed, so as to vary the rotary speed of the cam, according to the state of the crop or to the size of the sheaf.—Patent completed.

3791 W. MEAKIN, Great Woodstock-street. *Lock spindles.* Dated December 14, 1868.

One handle or knob of china or other material is firmly secured to one end of a square spindle, in any customary manner, with the ordinary attachment revolving in a rose plate firmly secured to the door. The other handle or knob (of china or such like material) has a metal bush or ferrule affixed to it, in the centre of which is a hole accurately tapped to suit a screw thread cut on the angles of the spindle; this metal bush or ferrule has a projecting collar, forming a circular recess to receive a disc of brass, iron, or other material.—Patent completed.

3792 H. E. NEWTON, Chancery-lane. *Producing power and motion.* (A communication). Dated December 14, 1868.

Motion is imparted by a pendulum to a shaft by gear wheels. The cogs of these wheels engage with each other and give the shaft a rocking motion. A working beam is keyed on this shaft, by which motion is conveyed to a crank by a connecting rod. This crank imparts a rotary motion to a fly wheel, the shaft of which is provided with another crank to convey the power and motion to a duplicate arrangement of parts, by a connecting rod attached to another pendulum by an adjustable connection. This pendulum is keyed on to a shaft, and as it oscillates, it imparts motion to a similar arrangement of parts to that just described. Speed wheels, which may be varied in size and multiplied in number, are employed to obtain any required speed for driving machinery.—Patent abandoned.

3793 J. J. STEVENS, Southwark. *Railway switches.* Dated December 14, 1868.

This relates, first, to a reversible switch lever, and consists in the mode of fixing to the lever the weight which holds the switches in their places.—Patent abandoned.

3794 S. W. SMITH, Leeds. *Spinning.* Dated December 14, 1868.

The object is to dispense with the "mule" in spinning, twisting, or doubling, and to operate directly and continuously, by means of a spinning frame, and this is accomplished by the use of a pair of hollowed rollers constructed as afterwards described.—Patent abandoned.

3795 J. ALLMARK, Oldham, and W. BLAKEY, Liverpool. *Tobacco.* Dated December 14, 1868.

This consists in enabling the operator to cut various lengths or thicknesses of tobacco at will, to accomplish which, there is attached to a false bottom, a half nut, working on a sceaw, such half nut being acted upon by a spring or other flexible material to keep the same in gear while working; by compressing the spring or other flexible material, the half nut is thrown out of gear from the screw. The false bottom can then be moved to any part of the box, for the purpose of cutting off any length or thickness of tobacco, or instantly removed to the true bottom of the box to receive a fresh supply.—Patent abandoned.

3796 C. E. BROOMAN, Fleet-street. *Locks.* (A communication). Dated December 14, 1868.

This consists in constructing locks or fastenings with a flush or non-projecting catch bolt, the object being to avoid the inconveniences of a catch bolt with an inclined plane, and which always springs out of its hole when the door is open.—Patent abandoned.

3797 W. J. MURPHY, Cork. *Ordnance.* Dated December 14, 1868.

This relates to improvements in the details of an invention for which letters patent were granted to the same invention dated December 11, 1865, No. 3127.—Patent completed.

3798 J. THOMAS, Gilbert-road. *Tea kettles.* Dated December 14, 1868.

This consists, chiefly, in providing a tea kettle with a

tube or tubes, or with one or more tubes and cups, so formed and arranged as to serve as passages for the heat and draught, so that the heating surface is greatly increased and rendered more effective while the fire is kept bright under the kettle by the free passages of air through the tube or tubes.—Patent completed.

3799 HON. LORD J. HAY, Piccadilly. *Engine counters.* Dated December 14, 1868.

The inventor proposes to employ a peculiar combination of levers in connection with a ratchet wheel or wheels. This combination consists of two groups or series of any number of levers, links, and pawls, the one group or series acting so as to rotate the ratchet wheel or wheels, whilst the other is making the back or return stroke, and *vice versa*, whereby a nearly continuous rotatory motion in the ratchet wheel is obtained. This motion is produced, moreover, at only one half the speed of the ratchet wheel, which is requisite with the ordinary intermittent ratchet motion, as the wheel, in such case, remains at rest during the back stroke, and, consequently, a loss of time is incurred, which has to be compensated for by extra speed in the wheel when in actual motion.—Patent completed.

3800 T. LYNCH, Enishowen. *Railways.* Dated December 14, 1868.

This consists, first, of friction strap lever brakes applied to the locomotive engine and carriages through the medium of drum wheels keyed to the driving and running axles of the engine and carriages respectively, by the arrangement of which the friction straps are caused to impinge tightly upon the peripheries of the drums by weighted levers acting in connection with the traction chains direct from the engine propelling the carriages, thereby supplying the requisite brake power to the train by the slacking of the speed of the engine aforesaid. And, second, in constructing locomotive engines for the above purpose with a firebox and smoke flue at each end, provided with ash pans, with or without regulators for admitting air to the furnaces or fireboxes, in which case the front firebox is used in connection with the after flues, and thus obviate the necessity in each instance of the engine requiring to be turned, and at the same time facilitate the entrance of the draught direct to the fire in the front firebox of the engine.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated June 22, 1869.

1902 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in apparatus or machinery for opening and closing gates, doors, or barriers, and for actuating semaphore signals by means of electricity.

1903 J. Martin, Chapletown-road, Leeds. An improved process for rendering cloth and other fabrics and materials repellent of water, and in the apparatus connected therewith.

1904 G. Musgrove, Pelton Colliery, near Chester-le-street, Durham. A new or improved apparatus for indicating signals in mines or shafts, or in other places.

1905 W. Clark, Gateshead-on-Tyne, Durham, and E. Walker, London-street, City. Improvements in the construction of windlasses.

1906 T. and R. Nuttall, Walmsley, near Bury, Lancashire. Certain improvements in weaving counterpanes, quilts, and other similar fabrics.

1907 J. C. Norman, Great College-street, Camden Town, Middlesex. An improved plough for ploughing land.

1908 G. M. Harris, Quay-street, Iron Works, Gloucester. An improved vice specially adapted for holding pieces of metal intended to be planed on planing machines.

1909 J. L Evans, Merthyr Tydvil, Glamorganshire. Improvements in the construction of apparatus for cold rolling iron for tin plates.

1910 R. R. Kelly, Manchester. Improvements in supplying furnaces with coal and other fuel, and in machinery or apparatus connected therewith.

1911 W. R. Lake, Southampton-buildings, Chancery-lane. An improved combustible compound.

1912 M. Henry, Fleet-street, City. Improvements in the mode of, and apparatus for, typographical composing and printing.

1913 H. T. Munns, Birmingham. Improvements in portable sketching camera obscuras.

Dated June 23, 1869.

1914 R. Moreland, jun., and D. Thomson, Old-street, St. Luke's, Middlesex. Improvements in steam rollers, also partly applicable to traction engines.

1915 W. Spence, Quality-court, Chancery-lane. Improvements in the manufacture of sugar and alcohol, and in apparatus for the purpose.

1916 J. H. Johnson, Lincoln's Inn-fields. Improvements in injectors for feeding steam generators.

1917 D. B. Park, Gracechurch-street, City. Improved means and apparatus for removing animal and vegetable deposits from the bottoms of vessels.

1918 A. J. Deblon, Fives-les-Lille, Department of Le Nord, France. Improvements in machines for calendering stuffs.

1919 O. Zabel, Quedlinbourg, Prussia. A grease box for all sorts of pistons, slides, &c.

1920 A. M. Clark, Chancery-lane. Improvements in electric telegraph apparatus.

1921 A. M. Clark, Chancery-lane. An improved anti-explosive or safety lamp applicable for mining and general purposes.

1922 H. A. F. Duckham, Camden Town, Middlesex. Improvements in gas regulators.

Dated June 24, 1869.

1923 R. Caunce, Mansfield, Nottinghamshire, and M. G. and B. Bradley, Nottingham. Improvements in machinery or apparatus for twisting yarns and other threads of cotton, wool, silk, or other fibrous substances.

1924 W. W. Neame, Birchington, Kent. Improvements in fencing, and in tools or apparatus for the manufacture thereof.

1925 R. N. Williams, Hackney-road, Middlesex. Improvements in the manufacture of reflectors for artificial light.

1926 S. Joy, Manchester. Improvements in apparatus for removing the dust from rag machines and other machines of a similar description.

1927 J. Macintosh, North Bank, Regent's Park. Improvements in waterproof varnishes and paints.

1928 J. Brooke and J. Hirst, Huddersfield. Improvements in certain fabrics technically known as paddings.

1929 J. Taylor, R. and J. Ingham, and J. Charples, Cranshaw Booth, Lancashire. Improvements in carding engines, by which the doffer is divided into spaces, such that the slivers are at will made of the same weight, and their width adjusted to produce rovings or slubbings, suitable for spinning cotton waste and similar substances.

1930 R. Olpherts, Ardee House, Ardee, Louthshire, Ireland. Improvements in shears and knives for reaping and pruning.

1931 A. H. Still and D. Lane, Cork. Improvements in the manufacture of gas.

1932 W. Bracelin, Robert-street, King's-road, Chelsea, Middlesex. Improvements in velocipedes.

Dated June 25, 1869.

1933 W. Palliser, Army and Navy Club, Pall Mall. Improvements in key fastenings for railway chairs.

1934 W. F. Williams, Broad-street, Golden-square, Middlesex. Improvements in boxes for holding jewellery and for other similar purposes.

1935 J. Heys, J. Duckworth, and G. Barnes, Haslingden, Lancashire. Certain improvements applicable to carding engines.

1936 H. Caro, Mannheim, Grand Duchy of Baden, C. Graebe, and C. Liebermann, Berlin, Prussia. Improvements in preparing colouring matters.

1937 J. Lamb, Kidderminster. Improvements in bobbin frames for carpet looms.

1938 A. B. Childs, Mark-lane, City. Improvements in catamenial sacks or uterine supports.

1939 C. Cochrane, Ellowes, Upper Gornall, Staffordshire. Improvements in the preparation of iron ores for smelting.

Dated June 26, 1869.

1940 W. Madders, Manchester. Improvements in, or applicable to, embroidering machines.

1941 F. C. Lecoultre, Geneva, Switzerland. An improved method of changing the barrels of musical boxes.

1942 J. Donald, Johnstone, Renfrewshire. Improvements in apparatus for finishing woven fabrics.

1943 J. Lomax, Hulme, Lancashire. An improved means or apparatus for arresting and depositing the stive or flour contained in the air discharged from millstones during the process of grinding.

1944 J. Lomax, Hulme, Lancashire. Improvements in apparatus for preventing the deleterious effects of back lash in driving millstones.

1945 F. Wohlgemuth, New York, U.S.A. Changing a breech-loading shot gun into a breech-loading rifle.

1946 A. Clark, Chancery-lane. Improvements applicable to the permanent way and rolling stock of railways.

1947 T. Gray, Union-road, New Wandsworth, Surrey. Improvements in the manufacture of varnishes.

1948 W. H. Perkin, Sudbury, Middlesex. Improvements in the manufacture of colouring matter suitable for dyeing and printing.

1949 G. Fielding, Leeds-road, Huddersfield. An improved smoke burner to be adapted to the flues of steam boilers.

1950 A. Bewring, Old Bond-street, Middlesex. Improvements in the manufacture of shirt collars.

Dated June 28, 1869.

1951 W. P. Wilding, Preston, Lancashire. An improvement in the construction of self-acting mules employed for spinning cotton.

1952 C. D. Abel, Southampton-buildings, Chancery-lane. An improved ventilating hat or covering for the head.

1953 M. Kennedy, New York, U.SA. Improvements in short levers weighing scales.

1954 J. W. Burton, Leeds, and R. W. Morrell, Bradford, Yorkshire. Improvements in the manufacture of combined woven and felted fabrics.

1955 G. T. Smith, Ordsall House, East Retford, Nottinghamshire, and C. Challenger, Retford, Nottinghamshire. A new or improved material or composition applicable to the manufacture of floor cloths, tarpaulins, railway sheets, and other waterproof fabrics.

1956 J. Howard, Bedford. Improvements in horse rakes.

1957 W. R. Lake, Southampton-buildings, Chancery-lane. An improved method of, and apparatus for, rendering and refining lard, tallow, and other fatty and oleaginous matters.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, JULY 9, 1869.

THE NITRO-GLYCERINE EXPLOSION.

WHEN our brief remarks upon the nitro-glycerine catastrophe at Cwm-y-glo were penned last week, no detail particulars had come to hand. Since that time, however, the facts have been fully made known by the daily press, so that it is only necessary here to refer to them very briefly before commenting upon the sad affair. It appears that about four tons of nitro-glycerine formed part of a cargo from Messrs. Nobel and Co., of Hamburg, to Carnarvon, consigned to their agents in Carnarvonshire. The ship was moored in the river Menai, and a portion of the explosive oil having been placed in the Llanddwyn magazine, the rest was brought in lighters and placed on the quay in Carnarvon. After waiting for some hours without the carts which were to have carried the nitro-glycerine to the mines having arrived, other men—who are stated to have been used to removing the material—with two carts, were engaged. These left about 4 p.m., on the Wednesday, with a portion of the nitro-glycerine, for Glyn-rhonwy quarry, in the vale of Llanberis. The two carts appear to have been of the most ordinary kind, and without springs, or any other means of absorbing the sharp jolts a rough road would inevitably cause. The carters proceeded through the village of Cwm-y-glo, where they had stopped to refresh themselves, and while still within sight of the loungers, the terrific explosion took place, which scattered death and destruction around. The details of scattered atoms of flesh, and fragments of the carts, are sickening, and may well be passed by; but to show the violence of the shock, we may mention that two holes of over 7ft. in diameter and depth, and about a horse's length apart, clearly indicated the fatal spot. The catastrophe occurred exactly where the diversion of a new road lately made by the Llanberis and Carnarvon Railway joins the old road, about 400 yards beyond the centre of Cwm-y-glo village, five miles and a-half from Carnarvon, and 300 yards from Pont Rhyddallt, the bridge that spans the narrow water uniting the upper and lower lakes of Llanberis.

Such, in brief, are the particulars of the explosion; the results were death to nearly a dozen persons, and serious injury to a great number more, besides a large destruction of property. A coroner's inquest was of course held, and a verdict of "accidental death" was returned. From this verdict we entirely dissent, as it is clear that the explosion was the result of sheer carelessness. The tins of nitro-glycerine were packed with straw in wooden cases, and placed for transport, over a rough mountain road, in a common tumbril. Thus, no precautions whatever were taken by the carriers to counteract the concussive effects of jolting upon this dangerous material. If no decent carts were to be had, or if there was no such thing as sand at hand wherein to bed the cases, they ought never to have been allowed to leave the quay. There is another and well known alternative with which, we should think, those in charge of the deadly material ought to be familiar, and that is to mix the nitro-glycerine with methylated spirit, which renders it perfectly harmless. Some one or other of these preventive measures certainly ought to have been taken. As, however, we cannot find that any precautions whatever were adopted, we attribute the explosion not to "accident," but to gross and culpable negligence.

But we go still farther, and say that an explosion—even an accidental one—of nitro-glycerine, ought never to occur at all, for the simple reason that it ought never to be used. We know its value to our miners, and should therefore hesitate to cry it down utterly, did we not also know that there is an equally efficient, but infinitely safer, material which ought to supersede it. We allude to dynamite, which is simply nitro-glycerine incorporated with sand, and by this means rendered harmless under every condition except that of being fired with a percussion fuze. Ordinary fire simply burns it quietly up, concussion will not affect it at all; but ignite it with a percussion fuze, and all its resistless energy is instantly developed. We speak from experience in this matter, having been present at a series of crucial experiments which took place about a year since, and which were fully reported by us at the time.* This substance is also the invention of Mr. Nobel, and we wonder that he can sell an ounce of nitro-glycerine, when a practically safe substance, giving equal effect, is to be had. But a few shillings a ton in favour of the dangerous commodity may be at the bottom of the matter, and this often makes all the difference in the world with some people, who are willing to accept any risk provided they can pocket a few pence by it. But unless some stir is now made to remedy the present hazardous condition of matters, the subject will most likely drop, and we shall not hear of it again until another, and perhaps far worse, explosion occurs. We are aware that there are rules and regulations with respect to the storage and transport of nitro-glycerine. All we can say is, that if they were observed on the present occasion, they are wretchedly inadequate for the purpose, and should be revised at once. If they were not carried out—and we cannot believe they were—then there must be a culpable party still in the background who ought to have seen to the enforcement of regulations affecting such important results. If—and there is still another hypothesis upon which the explosion may be explainable—if there was no one whose duty it was to see to the enforcement of these rules in a place where was a depôt of this deadly substance, then the sooner such a farce is ended by the appointment of a proper officer the better for public security. But we hope to see the matter well looked into, and nitro-glycerine superseded by the safe and valuable blasting agent—dynamite.

* See MECHANICS' MAGAZINE for July 17, 1868, p. 41.

STREET CLEANSING.

SO long as a drain or sewer is constructed of the proper dimensions, has a sufficient amount of fall bestowed upon it, and is kept well supplied with water, it will generally flush itself, or, in other words, be self-cleansing. The cause of sewers becoming choked up and stagnant, and, as a consequence, sources of infectious contamination, can in nearly every instance be traced to the violation of certain conditions, the fulfilment of which, every sanitary engineer is well aware, is indispensable to the efficient discharge of their contents. It will be acknowledged that a sewer performs its duty with the maximum effect when it conveys away from the neighbourhood of human beings and human dwellings, with the greatest possible rapidity, the excreta and refuse committed to its channel. This desirable result is, therefore, dependent upon the velocity imparted to the particles carried along in the current, which is, in its turn, dependent upon two conditions, namely, the fall, and the head of water, or other fluid conveyed away by its means. To a certain extent, these two requirements for effecting a rapid discharge of the contents are interconvertible, so that if it is impossible to employ one of them to the degree that would be considered advisable, the other may be availed of to a greater extent as a compensation. It is a mistake, however, to suppose that any amount of flushing will compensate for the defects inherent in a badly constructed and unscientifically designed sewer. Where the drainage of a town is dependent upon the action of sewers which have little or no fall, and are, besides, of a form and size which render them unfit for their work, there is no other remedy but to do away with them altogether, and establish the future drainage and sewerage of the place upon a better basis. In addition to the adoption of the best form of sewer, the most suitable and economical gradient and other particulars of a constructive nature, there is one precaution, the non-insurance of which will render that, of all others we have mentioned, completely abortive. This precaution consists in the adoption of means calculated to prevent "foreign substances" passing into the drains and sewers. Many persons indulge in the serious error that anything and everything that is in the nature of refuse may be discharged into the sewers; that, in fact, unless they carry away everything that is not wanted elsewhere, they are not fulfiling the purpose for which they were intended. Those who hold these opinions make no distinction between a sewer and a dustbin, and probably consider the latter a superfluous arrangement where the former exists.

The object of street cleansing is to prevent improper substances from passing into sewers, and thereby forming deposits and accumulations which the most powerful flushing would fail to dislodge. To effect this object, all street gulleys should, in the first place, be solidly and properly constructed, and well trapped. It is too much the practice for local boards, and other corporate authorities, to pay but little regard to this important desideratum. With a misplaced and false economy, they refuse to pay a price for gulleys, and what may be appropriately termed "sewer fittings," which would ensure their being of a good quality and proper construction, and prefer purchasing low-priced inferior articles, which are perpetually getting out of order, and ultimately becoming perfectly useless. Under these circumstances, it is no wonder that the *detritus* from the roads and streets finds a ready means of access to the sewers, and that the latter are frequently condemned for not adequately conveying away contents which should never have been permitted to enter them. The removal of all animal and vegetable refuse from the surface of the streets and roads of a town should be accomplished by scavenging and not by draining into the sewers. In the majority of our towns, this is effected with more or less completeness, according to the vigilance of the authorities, and the supervision they exercise over the more unscrupulous portion of the community. As a rule, there is a great deal more scavenging of the streets to be done than what is at all necessary. If a large number of the inhabitants of London were to make their ashpits and dustbins the receptacles of their domestic refuse instead of the streets, the cost of our metropolitan scavenging would be very much reduced. The scavenging of streets, in the simplest sense, signifies merely the removal of all surface refuse which is not of a nature suitable for being carried off by the sewers. In its extended sense, it may be taken to mean not only the removal but the ultimate sifting or sorting of its various components. Town refuse is of considerable value as a manure, but, unfortunately, the means for transporting it to the land are generally so very inadequate for the purpose that it is scarcely possible to dispose of it at a price that will at all pay for its collection. Any small profit that might be made out of it is altogether absorbed in the large outlay required for cartage or other mode of transport.

It is a subject for candid discussion, upon what principle the scavenging of towns should be conducted. Should it be carried

out by the local authorities themselves? or should it be placed in the hands of a contractor? In considering this point, there are two chief conditions to be borne in mind. The one is that of cost, and the other that of efficiency. So far as the former is concerned, the balance will undoubtedly lie upon the side of the contractor. A contractor who has abundance of plant and material at his command will be unquestionably able to undertake the scavenging of a town at a cheaper rate than the authorities could hope to execute it. This rule applies pretty generally to every description of work, although now and then notable exceptions arise. For instance, a very large amount of railway work has been done in India by the companies themselves, and, it is alleged, at a less cost than a contractor would have undertaken it for. At first sight, it appears as if a railway company could always do work cheaper than a contractor, but in making this comparison it is frequently forgotten that it requires a large outlay for plant and materials before the company is equally well fitted to undertake the work as the contractor. Passing from the question of the cost of cleansing streets to that of accomplishing it in the most efficient manner, the balance in this case is on the side of the local authorities. On the one hand, we have the interest of the individual, and, on the other, that of the community at large. However faithfully a contractor may adhere to his engagement, yet still he has to make his profit out of the job, and, in one sense, cares nothing about the sanitary welfare or health of the public. If the local authorities or their officers are lax in enforcing the conditions of the contract, it is not to be expected that the contractor would be the man to remind them of their duty. Moreover, in the event of any dispute or disagreement between them and him, the convenience of the public might be seriously interfered with pending the necessary arbitration and arrangements. Again, the local authorities have individually or collectively no interest in the execution of the work beyond a desire to perform it economically and in the manner that may be most conducive to the public welfare, and the conditions prescribed by all sanitary regulations. There are many large towns where the system of cleansing and scavenging the streets by contract has been tried and found wanting, and ultimately abandoned. Leeds, Manchester, Birmingham, and other towns, are examples in question. The item of watering must not be omitted in estimating the probable cost of maintaining the surface of streets and roads in proper order, and a liberal allowance must be made, as a long drought will cause a most material increase in the expenditure for this purpose. Hand labour is probably the best where the work to be done is on a comparatively small scale. Where, however, the town is sufficiently large, and the traffic sufficiently important and heavy, a great saving will be effected by the employment of sweeping machines and horse scrapers.

THE SOCIETY OF ENGINEERS AT CHATHAM.

JUST twelve months ago, we recorded the visit of the Society of Engineers to the Chatham Dockyard Extension Works, which are being built upon a large tract of marshy ground, formerly known as St. Mary's Island. Since that time, considerable progress has been made, and the works are now at a stage full of interest to engineers. Accordingly, last Friday, the members and associates of the Society made their second excursion of the present season, when they visited the works, by permission of the Lords Commissioners of the Admiralty. The "Oread" steamer was chartered for the occasion, in which the members and their friends, to the number of about one hundred, made a pleasant run down the Thames and up the Medway, luncheon being served on board on the way down. The band of the Grenadier Guards was on board, and added to the pleasure of the day by performing an excellent selection of music. Amongst the members present were Messrs. F. W. Bryant (president of the Society), W. Adams (vice-president), Baldwin Latham, W. H. Le Feuvre (past-presidents), G. J. Leonard, Robert Harris, George Waller (members of council), Alfred Williams (honorary secretary), Perry F. Nursey (auditor), G. W. Harris (secretary), A. E. Stephenson, W. Hendry, J. Westwood, R. Baillie, A. E. Walton, A. Latham, F. E. Houghton, J. Methven, E. Matheson, H. W. Hunt, G. W. Usill, &c., &c. Among the visitors were Messrs. J. Blackstone, W. F. Martin, A. Browning, E. Lane, W. Shephard, W. Le Senadey, J. Pullan, O. Byrne, J. Carey, E. Spon, F. N. Spon, J. Redl, L. Hislop, &c., &c.

On their arrival upon the works, the visitors were received by Mr. A. Gabrielli, the contractor, and Mr. Sidney Merton, his confidential agent, by whom, and Mr. Golla, Mr. Gabrielli's engineer, they were conducted over the docks. Although we described these works upon the occasion of the previous visit of the Society, it will be as well again to refer to them, as they are of considerable magnitude and importance. The extension docks cover an area of about 320 acres, and lie to the north-east of the present yard. The works, when completed, will consist of four graving docks, each of which will be 510ft. long, 80ft. wide at the coping, and 41ft. 6in. from floor to coping level. They will have 28ft. 6in. depth of water at the highest level of the neap tides. There are also three large basins, the combined area of which will be 74 acres, and the depth of water in each 30ft. at high-water neap tides. The first of this series of basins—the one nearest the town of Chatham—will be a repairing basin. The second, which is situated in the centre of the reclaimed marsh, will be occupied by ships having their engines fitted, and is called the factory basin. Alongside of this basin the factory will be built. In the third basin, vessels will be fitted out before proceeding down the river.

Many difficulties were encountered in the earlier stages of the work from water, &c., but these have been successfully overcome. The works are progressing very satisfactorily, and Mr. Gabrielli expects to complete them by Christmas, 1870, the time stipulated in the contract. In the first dock, the granite flooring is laid, and the sides are built up to the broad altar, or about half their intended height. The main culvert, with its branches and cesspits, in connection with a pumping engine, by which the docks will be emptied when the tide does not serve, is finished. In the second dock, the floor has been laid, and the entrance commenced; the third and fourth docks have not yet been commenced. In the first basin, which is called the repairing basin, the walls are in an advanced state, and the river entrance is being made. The entrance from this basin to the second, or factory basin, is also being made, and the walls of the latter basin are being built. The excavation of this basin will be effected by convict labour at the instance of the Government, Mr. Gabrielli having built a great part of the wall and prepared the trenches for completing the remainder. The works of the third or fitting-out basin have not yet been commenced. Not only is the progress of the work satisfactory, but also the character of the same, the construction being highly creditable to the contractor. The best materials are used, and the work is carried out in a thoroughly substantial manner. There is no doubt these docks, when completed, will compare well, in a constructive point of view, with any modern works of the kind. Mr Gabrielli is no new hand at this special branch of engineering construction, he having carried out the harbour extension at Malta, moles and breakwaters at Palermo, Naples, and Ancona. Before leaving the works, the visitors partook of refreshment which had been provided by Mr. Gabrielli, and which were especially welcome after a two hours' hot and dusty inspection.

While at Chatham, the visitors were conducted by Mr. Bernays, the clerk of the works in the dockyard, over the "Cerberus," double-turret ship, now lying at Chatham, and which is being fitted up for service in Australia. They also went through the shops in the dockyard, and inspected the "Sultan," 5,226 5-94ths tons, which is now in course of construction. The chief object of interest in the yard was the plate-bending furnace, which is heated by liquid fuel on the Dorsett principle. A generator, in which creosote is distilled, is placed near the furnace, and the gaseous product is conveyed by pipes to the furnace, where it is burned in jets. The advantages are, that the plates are heated in about a quarter the time required in a coal furnace, little or no scale is produced, and it is more economical than the ordinary process. This furnace and its performances will be found fully described in our issue for May 14 last. The armour plates for the "Sultan" are being heated for bending in this furnace, whilst a second and smaller furnace is used for heating thinner plates. The party re-embarked about half-past five o'clock, dining on board their vessel on the way up, reaching town about ten o'clock, after what will no doubt prove to be the most successful trip of the season.

MODERN PRACTICE OF THE ELECTRIC TELEGRAPH.*

AS telegraphy progressed in the Old World, so books and technical productions made their frequent appearance, and an English telegraph engineer's library now shows an extensive collection of both theoretical and practical works—the latter, we are glad to observe, being largely on the increase. In the New World, however, although telegraphy has increased with gigantic strides, the increase in telegraphic literature has been small and unimportant; and it is, therefore, with satisfaction that we notice the advent of a practical telegraph work. The author is Mr. Frank Pope, a gentleman of considerable experience in the American telegraph world, and the following extract from his preface will bear out the foregoing remarks:—"The works heretofore accessible to the American telegraphist have been of a popular rather than a scientific character, or else of so elementary a nature as to be of little service except to the most inexperienced student." To remedy this defect, the author has prepared this interesting work for the practical electrician and operator, supplying a want long felt, and more especially with reference to the American system of working, where details and other points differ materially from the different systems treated in "foreign works, the difficulty and expense of obtaining which has prevented their general circulation among the class for whom this treatise is more especially designed."

To ourselves, the most interesting portion of this work will be the descriptions of the different apparatus used for signalling in America, and the various methods of insulation adopted; but to those for whom the work is written, the most valuable part is undoubtedly the descriptions relating to the use of batteries, Ohm's laws, and "testing telegraph lines." The author remarks on this latter point, "the apparatus and methods

* "Modern Practice of the Electric Telegraph; a Handbook for Electricians and Operators." By FRANK L. POPE. New York: RUSSELL BROTHERS, 28, 30, 32, Centre-street. 1869.

now in general use in this country are of a somewhat primitive nature, but the improved modes of testing which have long been employed in Europe are gradually becoming appreciated here, and as these are based on sound scientific principles, it is to be hoped that they will soon supersede the imperfect ones heretofore employed." A long chapter is given to this subject, and the method of calculating the distance of various faults by resistance measurements is given. A description is given in the appendix of Thomson's reflecting galvanometer, and a number of well-known useful formulæ are given. The technical phraseology frequently differs somewhat from ours: "ground" for earth, "cross" for contact, "to ground a wire" for to put to earth. The following description of our ordinary "weather contact" will show the peculiarity :—"Weather cross.—The escape of the current from one wire to another upon the same poles, owing to defective insulation, is sometimes wrongly called 'induction' in 'sympathetic currents.'" Weather cross is a much more appropriate term. Our climate being moist, we are, consequently, liable to this sort of fault, and to obviate it have for years used an earth wire from the arms or supports down the pole to the earth. Any escape or leakage that may take place, due to the weather lowering the insulation, will then go to earth instead of from wire to wire. "This practice," the author thinks, "might be adopted in America with great advantage to the working of the lines."

A chapter containing "notes on telegraphic construction" is very useful, and contains much valuable advice. Amongst the notes is given the plan adopted by the Bishop Gutta-Percha Company for making joints in gutta-percha covered wires. One special instruction in italics we cannot help noticing, "Use no spirit lamp, nor anything with a flame." The gutta-percha is heated by being placed near a hot iron. It is strange that with us no joint whatever is made without the assistance of a spirit lamp, and that frequently applied; and yet of the countless joints annually made in this country, how rare it is to hear of an experienced jointer making otherwise than a good joint.

From a careful perusal of the present work we are assured that it supplies a long-felt want, and it is more than probable that it will tend much to improve the knowledge of electricity and practical telegraphy amongst the operators, enabling them to obtain some technical knowledge of the apparatus they are constantly using. But we cannot dismiss the work without noticing the wholesale manner in which extracts have been taken from some of our English works. We allude more especially to the works by Mr. Culley on "Practical Telegraphy," and Mr. Clark's "Electrical Measurement." The author seems to imagine that his slight acknowledgment of obligations for the excellent works are amply sufficient.

THE FRENCH ATLANTIC CABLE.

VARIOUS conjectures were made as to the causes that compelled Sir S. Canning to cut and buoy the cable. But few imagined that at this period of the year a violent gale should have brought about that result. The gale must have been severe, for the "Chiltern" lost her lifeboat. At the time the gale came on, a sudden fault made its appearance. This was known at Brest; but it is satisfactory to find that on the weather sufficiently moderating to allow the resumption of work, the cable was picked up, the fault removed, and paying out proceeded with as if nothing had happened. However much we may regret the appearance of these faults, and the sudden advent of a gale of wind, yet it will be found that the occasion is one that brings with it the knowledge how operations in water two miles deep can with such facility be carried on. A fault arises, the vessel is stopped, the cable picked up until the faulty part comes within reach, when, after its removal, paying out goes on again. A gale of wind suddenly arises, the cable is safely buoyed, and the paying-out ship lays to within sight of the buoy, and resumes operations when the weather has sufficiently improved. One of the greatest risks in paying out a long submarine cable has been generally considered to be the uncertainty of the weather; but the present successful operations would seem to have reduced that risk so much as to eliminate it altogether.

The statement showing the progress of the work we continue from our last week's number :—

From the preceding table it will be seen that the progress of paying out is satisfactory, and that by the decrease in the slack the depth of water has decreased. The electrical condition is reported perfect. The "William Cory" has laid the shore end and intermediate portion off St. Pierre, and the end is buoyed ready for the arrival of the "Great Eastern." If all goes well, and the same satisfactory progress continues, we shall shortly be able to announce the successful submersion of this the largest and most important section of this great enterprise.

THE METEOROLOGICAL SOCIETY.

THE annual meeting of the Meteorological Society was held on June 16, at the Institute of Civil Engineers. The chair was taken by the president, J. Glaisher, F.R.S., and among the fellows present were Drs. Tripe and Mann, Messrs. Silver, Symons, Eaton, Dines, Perigal, &c. Seven gentlemen were elected fellows. The first paper read was upon snowfall in Canada, descriptive of its average amount, seasonal variations, and the nature of the snow drifts of the country. Being mainly statistical, it afforded little matter for discussion, but it was remarked by the president and Mr. Doggett that when the fall of snow was excessive in Canada the weather was warm here, and this seems an inference worthy of investigating. The next paper was a sequel to two previous communications, by Mr. C. Meldrum, on the relative position and direction of air currents in the South Indian Ocean. These papers confirm, for the southern hemisphere, the law of wind in relation to atmospheric pressure, already abundantly proved for the northern hemisphere. The author contends that cyclones originate between the north-westerly or tropical current and the south-easterly or polar wind of the southern ocean, only when the former is situated on the northern edge of the latter. When these conditions are reversed, calms or moderate winds alone ensue. This is exactly what was to have been inferred by analogy from what has long been well known for the northern hemisphere. The author asserts that this knowledge affords a basis for weather forecasts, as did Admiral Fitzroy, of whom he is evidently a very able disciple. He should, however, have taken less credit to himself, and given more to others whose labours have cleared the jungle and made the path so easy for him.

Mr. J. Martin described a self-registering aneroid manufactured by the Stereoscopic Company, which was exhibited and attracted a great deal of attention. It was certainly an excellent piece of work, though of its scientific accuracy of course we cannot speak.

Mr. Doggett read a paper on the signs of weather afforded by average temperature and monthly rainfall. Compensation is the law of nature, and indefinite cold or heat, rain or drought, can no more be expected at any place, than darkness without the due proportion of light. But the laws of this compensation as regards meteorological periods have yet to be determined, and such researches as Mr. Doggett's will render important service in opening up this much neglected branch of the science. A short portion was read of a paper on the height of the barometer in relation to the direction and force of wind, by Mr. R. Strachan. As the proceedings had not yet occupied an hour, and the paper was a short one, its curtailment by the president seemed very uncourteous, more especially as he immediately allowed Mr. Casella to describe a form of Sixe's thermometer which he has effected for deep-sea soundings, which can be made to resist a hydraulic pressure of about 3 tons on the square inch without error of indication. We do not ourselves know of an investigation, taking account of the force of wind as well as its direction in connection with the height of the barometer, although such investigations are calculated to throw considerable light on the value of the barometer as an indicator of weather to an isolated observer.

The report for the past year was next brought forward. Strange to say, it seemed concerned less about the business and progress of the society than about extraneous affairs, and appeared to be excessively voluminous, for only scraps here and there were read. It announced that the fellows numbered about 320, that the society has above £1,000 invested in the funds, and that hopes are entertained by the council of receiving recognition and aid from the Government in the shape of apartments for offices and meetings. The society has rendered much valuable service to the public, while its utility is capable of great extension; therefore, the boon sought is one well deserved and likely to be of public advantage. The members of the society are at present ridiculously few considering the vast interest taken in meteorology by the public generally. With fitting accommodation and, especially ready access to its library, which is now quite inaccessible, the society ought to expand greatly both in numbers and importance. The usual votes of thanks were given to the officers, and a very pleasing part of the proceedings was the warm and laudatory terms in which the meeting recognized and recorded a vote of thanks for the generosity of the Institute of Engineers, in gratuitously accommodating the society with a meeting room, as it has done for many years.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

THE DENSITY OF HYDROGENIUM—THE EFFECTS OF CORALLINE—THE OXYHYDROGEN LIGHT SCHEME—PEROXIDE OF HYDROGEN IN THE AIR.

MR. GRAHAM, whose demonstration of the metallic nature of hydrogen we noticed some time ago, has corrected, with the candour that characterizes the true philosopher, an error into which he fell in determining the density of solid hydrogen, or hydrogenium as he calls it. In making this determination, he at first proceeded on the assumption that the density of the palladium, with which the hydrogenium was associated, remained constant. This, however, he has found is not correct. He has satisfied himself that there is

a change in the molecular condition of the palladium. Taking this into consideration, he finds that his former estimate of the density of hydrogenium was much too high, and now gives us the figures 0·73 as the true density.

We mentioned some time ago the irritation of the skin produced by red socks and stockings, and said that the effects had been traced to a dye known as coralline, and prepared from carbolic acid. There are very wonderful stories told of the effects of this dye, both in this country and in France, but it seems that they must be received with some doubt. M. Landrin states that he has made numerous experiments with the substance on animals and on himself, applying it externally and internally, and has found it to produce no effects whatever. M. Chevreul also told of a dyer who dyed his arm with coralline, and suffered no unpleasant consequences from it. It is very difficult to arrive at the truth in matters of this kind. The skins of different people differ greatly in sensibility, and what produces no effect on one person will excite the greatest irritation in another.

The oxyhydrogen light scheme has now taken a definite shape in Paris. A company has been formed, the capital necessary has been raised, and application has been made for permission to lay down pipes to carry oxygen and hydrogen over about a fourth of the city. It is not very likely that the permission will be granted, and the promoters will have to confine themselves to supplying individuals with compressed gases, as was originally proposed. We have published the patented processes by which M. Tessié du Motay obtains the oxygen and hydrogen which he proposes to distribute over Paris, at a cost so low that the oxyhydrogen light is promised much cheaper than common gaslight; but ingenious and relatively cheap as they undoubtedly are, it is impossible to believe that the service can be made so inexpensive as to supersede coal gas. The prospectus of the company enlarges upon the cheapness and purity of the light, the complete combustion, and the absence of all deleterious matters in the products of the combustion; but is quite silent as to the danger of introducing into a house two gases not possessing any smell, and which, consequently, may escape without observation, and the mixture of which forms an explosive compound of far greater power than any mixture of coal gas and air. To any danger of this kind, continental engineers appear to shut their eyes. We saw, a short time ago, a patent taken out in Belgium for making a mixture of coal gas and air, storing it in gasholders, and distributing it over the city of Brussels for heating purposes. The engineering details given showed a complete knowledge of the subject of the manufacture and distribution of gas, but there seemed to be no recognition of the risk, imminent enough, of blowing up the whole concern. A consideration of this kind, some years ago, stood in the way of a scheme of the kind projected for Birmingham, and will, no doubt, now prevent the Oxyhydrogen Light Company from getting permission to lay down their pipes over Paris.

The information comes all the way from Tiflis, in Persia, that peroxide of hydrogen has been discovered in the air. Schönbein, who had no doubt of its existence in the atmosphere, never succeeded in demonstrating its presence. This success, however, is claimed by M. Struve. Along with the peroxide of hydrogen, the discoverer always finds ozone and nitrite of ammonia. These were also found in hail and in sea water. In these days, when the origin of nitrates of water is so warmly debated in connection with the question of the possible previous sewage contamination of water, we are fortunately reminded by M. Deville of the fact that he collected snow on the Andes, at the height of about 14,000ft., which yielded a large amount of nitric acid, doubtless derived from nitrite of ammonia, which Struve has now discovered in the air.

PARLIAMENTARY NOTES.

In the House of Commons, on the evening of yesterday week, Mr. Knight asked the Secretary of State for War, whether reports had been received from the military authorities of the Presidencies of Bombay and Madras highly commendatory of Major M'Gwire's camping system with field hammocks as calculated to add greatly to the health and efficiency of troops in the field and on the line of march; and, if so, whether it was the intention of the Government to extend the full benefits of such system to British soldiers in India and the colonies.

Mr. Cardwell said that the reports from Madras and Bombay were favourable to the system, but they were not approved of by the Commander-in-Chief in India, and their adoption was not recommended by the Government of India. Until they were approved of in India, it was not probable they would be generally adopted.

Mr. Hoskyns asked the Secretary of State for War when it was the intention of the Ordnance officers to proceed with the cadastral survey of the midland and southern counties of England on the same (6-inch) scale already adopted in Ireland and in some of the northern counties; and whether it was in contemplation to enlarge the scale to 25in.—*i.e.*, about a square inch to the acre.

Mr. Cardwell replied that the midland survey had not been proceeded with, but the survey of the southern counties was in progress, and he believed that the whole would be completed in about fifteen years.

At the same sitting, Mr. Charley asked the Secretary of State for the Home Department, whether the Government intended to take any steps this session to carry out the recommendation of the report recently presented to Parliament, on the Print Works Act and Bleaching and Dyeing Works Act; and that print works and also bleaching and dyeing works should, subject to modifications, be placed under the general provisions of the Factory Act.

Mr. Bruce said that a bill was in preparation, but he did not think it possible that it could be passed this year.

Mr. Peek asked the Postmaster-General whether the proposed monopoly of telegraphic messages would in any way interfere with wires already in operation, or which in the future might be desired, between the offices and works of manufacturing and other firms, which were frequently separated by a considerable distance.

The Marquis of Hartington replied that it was not intended in any way to interfere with telegraphic communications used in private business.

On Monday evening, the question of a Parliamentary grant for the Faraday memorial was opened by Dr. L. Playfair, who asked the Chancellor of the Exchequer whether the following extract of a letter, purporting to be written by him, dated May 5, 1869, and read at a public meeting on June 21, was correctly reported:—"I do not in the least doubt the signal merits of Faraday, and I hope that a monument may be erected worthy of so great a man; but I cannot consent to appropriate public money towards the monument of a private citizen, however illustrious. I do not make this rule: I find it." And, if it was a correct extract, whether he would state to the House the exact terms of the rule to which he referred, and the date at which it was made.

The Chancellor of the Exchequer said that the extract was perfectly correct, but he was sorry to say that he was unable to state the exact terms of the rule, which was derived from practice. He had a list of the statues in London, putting aside kings; they were fifteen in number. Of these, one, the statue of Nelson, was erected partly by Parliamentary grant and partly by public subscription. The statue of Richard Cœur de Lion was erected by Parliamentary grant, aided by private subscription. The statue of Sir John Franklin was erected entirely by Parliamentary grant. All the other statues in London had been erected by private subscription. From that practice he deduced the rule that it was not the practice to appropriate public money towards the monument of a private citizen, however illustrious. The history of England also showed that the practice on this point had always been uniform. Such illustrious men as Shakespeare, Milton, Locke, and Newton, were without statues erected at the public expense, and therefore Faraday must feel content to be passed over in such company. The incentive to action had been regard for duty more than a love of glory. And certainly the nation which was prodigal of public monuments was not in the ascendant scale.

At the same sitting, Lord G. Hamilton asked the Secretary of State for the Home Department if it was the intention of the Government to adopt the suggestion contained in the verdict of the jury at the recent inquest at Hounslow, viz., that the Government should appoint permanent inspectors to carry out more strictly the purposes of the Gunpowder Act.

Mr. Secretary Bruce replied that the subject was under consideration. The accident could not be traced to any fault on the part of the Government, for a very short time before the occurrence the establishment was carefully examined by Colonel Younghusband and Captain Smith, who reported that everything was as it ought to be.

THE PAYING AND NON-PAYING WEIGHTS PULLED BY THE LOCOMOTIVE ENGINE IN 1867.*

By Mr. B. Haughton, C.E.

The railway statistics published by the Board of Trade annually, as far as they go, are of vast importance in determining the quantity and cost of the useful work done by the locomotive. In a country such as the United Kingdom, possessing 14,247 miles of railway (or 22,091 miles of single line), which has been made at a cost of £502,263,000, equal to £35,253 per mile (or £22,736 per mile of single line). In which the receipts from railway traffic are £39,480,000 per annum, or £119,636 per day (in all such calculations I assume that the year contains 330 working days). In which 287,688,000 railway trips (not including those of season ticket holders) are made in the year, equal to 871,781 trips each day, each trip 12¾ miles in length. In which 148,253,800 tons of goods, minerals, &c., are carried per annum, equal to 449,250 tons each day, each ton pulled over say 25 miles. In which 6,328,490 trains are started per annum, equal to 19,177 trains each day. In which the locomotive travels 148,542,827 miles per annum, or 450,129 miles each day. Which has been the cradle of the railway, and in which it and its complement, the locomotive, were first invented, constructed, and brought into operation. In such a country the question of the administration and conduct of the railways must be a paramount one; and we cannot as its people be said to have done justice to this magnificent piece of mechanism until we shall have so investigated its economy, and the science of its action and effort, as to place beyond dispute the laws of its existence.

It is particularly desirable that such should be studied at the present day; there is just now a lull in the railway atmosphere; railway construction, incessant for the last forty years, has at length ceased; the engineer is idle, the capitalist without whose co-operation he dare not lift his hand, stands aloof; the public look on and suffer from the estrangement, and their occupation in this department of their manifold labours being gone (for the construction of 552 miles of single line per annum since 1827, with its attendant expenditure of £12,500,000 yearly, must have been to them a source of much and very profitable business); they began during their enforced leisure to examine and criticize the natural history of the giant that they have created, with the view to bending him to a more tractable and economic servitude; and in truth most wildly and inconsiderately have they approached the investigation. We cannot altogether blame them for having placed themselves so far under the guidance of *doctrinaires*. He who, by virtue of his office, ought to have been their guide in their attempt to solve the various questions at issue has not come forward to assist them with his counsel, and out of his practical and special knowledge of the situation. The engineer which an immense material development in the current century has produced, has been so entirely absorbed in and devoted to the physical side of the railway question, that he really has not had time to consider its moral aspect. As soon as he shall have done so, and explained the condition of affairs, we may reasonably expect that the aforesaid public will become contented with "things as they are," as the intelligent British public always is, when light is given to it, and when it is made aware by the logic of facts that "things cannot be otherwise."

I hardly ever remember to have seen the truth so persistently distorted as of late by certain pamphleteers, magazine writers, and ambulatory orators, in regard to this question. In one case, a most elaborate literary picture has been drawn in an article styled "The Great Railway Monopoly," the object of which appears to be to induce the Government to undertake the management of the

* Read before the Civil and Mechanical Engineers' Society.

railways of the United Kingdom; to confer upon the travelling public the benefit of low fares; and to prove indirectly the total incapacity of those who have the control and direction of the railway *menage* of the country. The article is remarkable for the display of much research, and in short conveys the idea that it comes from the hand of an accomplished and fluent compiler. It, however, reminds the engineer of a grand and boldly designed arch of masonry under construction; it is perfect as to the material selected, its foundations are on a rock, its abutments, its counterforts, and haunches are undeniable, but it fails to support itself on the withdrawal of the centreing, because of the omission of one simple though indispensable feature—the key—which in the case of this slap-dash article must be supplied by the engineer, and the absence of which stamps the writer as being a literary conjuror rather than a practical man. With such instructors as these alluded to, and the magicians of the Belgian State lines, it is not to be wondered that the English public are disturbed as to the condition of their railways. It is not surprising that, at the first blush, they should believe themselves to be the victims of a selfish association of monopolists, and that this immense property is tended and controlled by an executive of quacks, who are guided by the leading idea that high fares alone will generate income; never was a more unfounded belief fostered.

The railways of the United Kingdom at the present day are conducted by an accomplished, scientific, and highly skilled body of experts, who know their business, do it, and don't talk about it, and who, moreover, take out of the locomotive all they can, and present it freely and exuberantly to those whom it is their interest, as well as their pleasure to accommodate—the travelling community; as shall presently be shown, this is, as the "Times" has lately stated, "the best served travelling community in the world," though I cannot endorse the final phrase in the sentence, that it is "the most ungrateful," because ingratitude is a vice of the weak and the unintelligent, and I cannot admit that my countrymen belong either to the one or the other class, but the rather that, having been made aware of the actual condition of affairs, they will accept it as being, on the whole, the best possible, considering all the circumstances of the case, and will unite with those who are only too well pleased to be assisted by them in concerting means for the elimination of such minor defects of the railway system as exist, and which are only those that belong to every human institution, but which, nevertheless, we must combat unceasingly, so as to attain as much perfection as our knowledge of the sciences involved will admit.

To begin, accordingly, the work done by the locomotive in 1867, the last year for which the Board of Trade Returns have been published, was, viz:—

3,924,624 passenger trains pulled 19·08 miles each.

	Tons.	Per cent.
Paying weight . . .	27,472,368 ...	4·89
Non-paying weight .	533,748,864 ...	95·11
	561,221,232	100·00

2,403,866 goods trains pulled 30·64 miles each.

	Tons.	Per cent.
Paying weight . . .	146,635,826 ...	30·34
Non-paying weight .	336,541,240 ...	69·66
	483,177,066	100·00

6,328,490 total number of trains pulled 23·47 miles each.

	Tons.	Per cent.
Paying weight . . .	174,108,194 ...	16·67
Non-paying weight .	870,290,104 ...	83·33
	1,044,398,298	100·00

Horizontal mile tons.

Passenger trains	10,708,101,106
Goods trains	14,804,545,302
	25,512,646,408

This work was done by 8,619 locomotives, showing work done by each, per annum, 2,960,047 horizontal mile tons; work done by each per day, 8,969 horizontal mile tons, equivalent to 382 tons pulled 23·47 miles per day, and further 17,234 miles run by each engine per annum.

Taking the 23·47 miles, the actual average distance run by each train per day, as consisting of an ascending gradient of 1 in 300 for half the distance or 11·735 miles, and a descending gradient for the remaining half; and assuming 26 miles per hour to be the average speed of each train, equivalent to an exercise of horse power as under:—

Train Mileage of Board of Trade Returns.

$$\frac{148{,}542{,}827}{3{,}924{,}624+2{,}403{,}866} = 23{\cdot}47 \text{ miles run by each train per day.}$$

Total Train Tons.

$$\frac{1{,}044{,}398{,}298}{3{,}924{,}624+2{,}403{,}866} = 165{\cdot}03 \text{ tons' weight of each train.}$$

Average inclination, 1 in 300 up for 11·735 miles; and 1 in 300 down from the same distance.

Average speed, 26 miles per hour.

From these data are obtained the results:—

$$\frac{26 \times 5280}{60} = 2288 \text{ feet run by train in 1 minute.}$$

$$\frac{2288}{300} = 7{\cdot}626 \text{ feet lift of train in 1 minute.}$$

$$\frac{165 \times 2240 \times 7{\cdot}626}{33{,}000} = 85{\cdot}41 \text{ horse power due to lifting the trains.}$$

$$\frac{165 \times 9 \times 2288}{33{,}000} = 102{\cdot}96 \text{ horse power due to friction, \&c., at 9lb. per ton.}$$

$$+85{\cdot}41+102{\cdot}96 = +188{\cdot}37 \text{ horse power required in ascending the incline.}$$

$$-85{\cdot}41+102{\cdot}96 = +17{\cdot}55 \text{ horse power required in descending the incline.}$$

$$+188{\cdot}37+17{\cdot}55 = 205{\cdot}92 \text{ horse power exercised throughout the average run of 23·47 miles.}$$

Trains. Trains per Day.

$$\frac{6{\cdot}328{\cdot}490}{330} = \frac{19{\cdot}177}{8619{\cdot}} = 2{\cdot}22 \text{ trains pulled per day by each engine.}$$

Each train pulled 23·47 miles, at 26 miles per hour, gives 54·16 minutes occupied in the average journey.

$$\frac{54{\cdot}16 \times 2{\cdot}22 = 120 \text{ minutes.}}{60} = 2 \text{ hours.}$$

205·92-horse power × 8619 engines = 1,774,824 total horse power exercised for 2 hours each day of 339 days per annum, in behalf of the travelling public.

Considering that these engines may be held on the average to be capable of exercising 400-horse power each without forcing; the 206-horse power actually made available will perhaps be considered too small a per centage to take out of each engine, but it will be understood that it is not possible to render useful the maximum power of the total number of engines in the country, for these reasons; that a certain portion must be held in reserve in case of ordinary accident to running engines; that another portion will be engaged as bank engines, and in shunting trains about the stations; that a large proportion of the whole will stand in the sheds for cleaning, and in the shops to undergo the repairs due to the daily wear and tear of an exceedingly complicated and perishable machine; and that over and above all these requirements an ultimate reserve will be necessary in order to make sure that a provision shall exist against all eventualities, and that in no possible case shall the company fail to perform their duties to the public punctually as advertised in the time bills. These results cannot be taken as illustrating the work to be gotten from individual engines, but only as being useful in comparing the total work of one year with that of another in the same country; in comparing the work done in one country with that done in another; and above all and eminently, in showing a people how much they take from their machinery in gross, with the object of exhibiting the weaknesses of the system, so as to effect such reforms as shall lead to improvements in organisation and administration thereafter.

In reviewing the foregoing figures, I shall ask your attention to two salient matters therein exhibited, the first of which is that I have reduced the work done to horizontal mile tons, and that I believe this to be the only true mode by which a railway company can accurately test the nature of its operations; and, secondly, to the extraordinary preponderance of the figures indicating the non-paying weight pulled as compared with the paying weight, viz.:—Firstly, the usual mode of estimating the work done, as practised by boards of directors, is that by train mileage. The train mileage of one half-year exceeds that of the corresponding half in the previous year, and this is hailed as a matter of congratulation from the chairman to his proprietors; or the increased income per train mile of the half-year has exceeded that of the corresponding six months of the former year by a certain per centage, which is equally a cause of satisfaction to his audience; whereas it is quite within the range of possibility, and has no doubt happened before now, that each of these apparently pleasing results of the half-year's work has been nothing less than a captivating illusion; for, in the first case given, that of an increase of train mileage, the latter may have increased without bringing an increase of revenue, and may have brought with it a positive loss; and, in the second case, that of an increased income per train mile, the same may have arisen in consequence of a reduction of mileage, and may have existed coincident with a falling off of revenue. The train mile is not a measure of the useful work done, because the weight of the train is not told; given the weight of the train, however, subdivided into its paying and non-paying weights, and a basis of calculation is afforded which places the work done beyond cavil.

In order to attain this object, it will be necessary that the paying and non-paying weights of each train started shall be registered, as well as the distance travelled by each vehicle. This, though causing some extra office work, will amply pay for itself in the long run. I have endeavoured to reduce the work done, as given in the Board of Trade statistical tables to the horizontal mile ton by rating the weights of the average trains of the year as follows. It will be observed that some of the items in the tables are assumed. I have determined their value as best I could from the most reliable sources I have been able to consult; the remaining items are taken from the Board of Trade returns, viz.:—

Weight of the average passenger train in 1867—

Non-paying load.		
Engine and tender . .	50 tons.	
7 carriages	56 „	
2 breaks	10 „	
		116 tons.
Empty carriages, &c., to be pulled back, say, $\frac{1}{6}$th of above . .		20 „
Paying load.		
73 passengers, with luggage, &c., at 2 cwt. each . . .		7 „
Total		143 tons.

I have chosen 7 as a fair average figure for the carriages to each train. This number of composite carriages should contain, if full, 196 persons, narrow gauge; and in corroboration of this rating, I may quote Mr. Robert Stephenson, who in his address to the Institute of Civil Engineers in 1856, rated the then trains as capable of holding on the average 200, while not actually carrying over 100 passengers. It appears from the Board of Trade returns that the number of passengers has decreased since then, doubtless owing to competition, and the wish to render travelling more attractive by the running of an increased number of trains, since only 73¼ passengers were carried per train in 1867; or it may have been more directly due to the practice of sending through carriages to all the principal stations with the more important trains, thus saving their occupants the necessity of changing from one carriage to another *en route*. The empty carriages to be pulled back with their attendant portion of the weight of the engine, consequent on the irregularity of flow of the streams of traffic in opposite directions, is a fact that cannot be evaded, I have rated it at one-sixth the non-paying weight.

(To be continued).

A NEW REFRIGERATOR.

A VERY useful application of scientific principles, and one which will be appreciated during the present hot weather, has been made by Messrs. Wright and Co., of Broad-street, Birmingham. This consists of a portable refrigerator, in which water is used instead of ice. It consists of a close-topped metal cover, surrounded by a rim containing water, and covered with a porous textile fabric. By capillary attraction, the water rises over the whole surface, evaporation immediately ensues, and a cooling effect is produced. A great advantage this invention possesses over all others is, that the warmth of the atmosphere is the means of producing the cooling effect, so that, while in very hot weather the difference between the inside of the refrigerator and the external air is very great, in cold weather, when not wanted, there is no perceptible difference. It will be seen that this refrigerator cannot fail to keep provisions cool during the hottest weather, as the principles by which the effect is produced are the operation of natural laws.

THE Russian Government has issued a ukase for a universal exhibition, to be held at St. Petersburg next year, to open on May 15.

SELF RECORDING ANEMOMETER.

BY MR. BECKLEY.

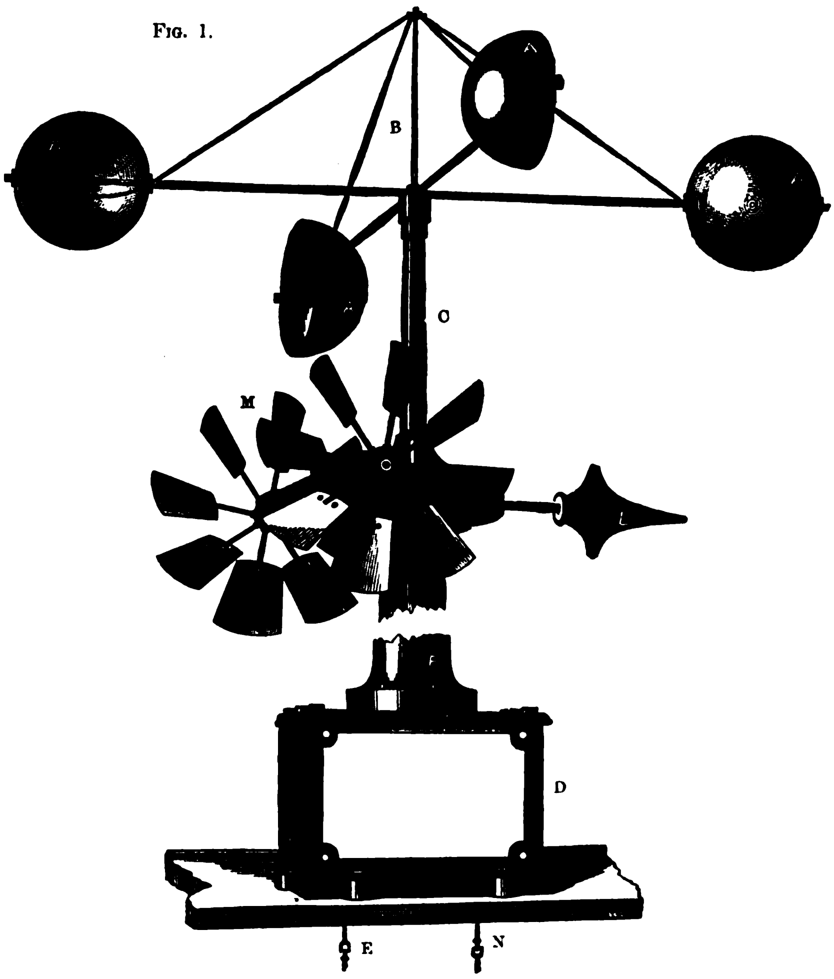

Fig. 2.

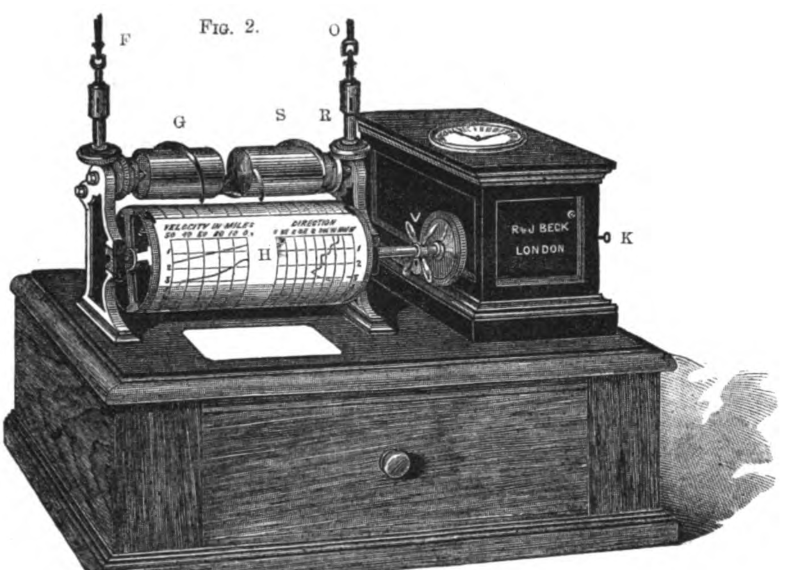

SELF-RECORDING ANEMOMETER.

THE annexed engraving represents the self-recording anemometer used by the Board of Trade, and which is the invention of Mr. Beckley. The apparatus was designed to register the velocity and direction of the atmospheric currents from day to day. It consists essentially of two parts; the first—which is shown in fig. 1 drawn to a scale of 1-12th—is fixed in an exposed position on a roof, or elsewhere, and the other (fig. 2), drawn to a scale of 1-6th, may be placed wherever desired, and is connected by light brass tubes to the first portion. Upon the wind moving the hemispherical cups A A, the motion is communicated to the steel shaft B, which passes inside the shaft C, and is fitted at the lower end with an endless screw that works into a series of wheels in the iron box D. The velocity is here reduced, after which it passes out at the point E, and at the required distance is connected with the rod F, where, by means of bevel wheels, it communicates the motion to the spiral brass registering pencil G, which is arranged so that each revolution records 50 miles of velocity upon the prepared paper H, placed on the drum, which is revolved once in 24 hours by the clock K.

The direction of the wind is indicated by the arrow L, which is kept in position by the fans M. These are attached to a spindle with an endless screw attached to the shaft C, and working into a worm-wheel screwed into the column P. This spindle passes into the iron box D, where it works into a tooth-wheel, and emerges at the point N, passes down side by side with the velocity-rod till it reaches the point O, where it is attached to a pair of bevel wheels at R, and communicates the movement to the pencil S, which, in one revolution, records the variations through the cardinal points of the compass on the same paper as that on which the velocity is given. The paper is held on the drum by two small clips, and may be easily changed by unclamping the cross V, without removing the drum or in any way disturbing the instrument.

As the self-recording anemometer is a differential instrument, it will be well for those who desire to have one, to select the same pattern as that established by the Board of Trade as a standard (for the sake of comparison with others). The main features and advantages of this form are:—The convenience of recording both direction and velocity on the same sheet of paper; the advantage of the employment of spiral pencils recording on De la Rue's metallic paper, and which, being made of brass, never require renewal, and register with certainty, however often the wind may shift or however great its velocity; the reduction of the speed of the velocity-shaft before communicating the motion to the long rods, thus avoiding much friction; and, finally, the ease whereby, owing to peculiarity of construction, every working part can be hung and balanced so as to reduce the friction to a minimum. We are indebted for our particulors to Messrs. Beck, of 01, Cornhill, who are the monufacturers of the apparatus.

THE KING'S LYNN DOCK.

FOR many years past the necessity of having a dock at Lynn has been felt, and the question has several times been discussed, without any practical result. When the Ouse had been diverted from its old bed to the famous Eau-brink cut, the Great Eastern Railway Company projected a dock in the old channel. The project, however, was neglected until the Midland Company, by its new line from Peterborough, established a rivalry with the Great Eastern. Then there was a fight for the honour of constructing the dock, in which the Lynn and Sutton Company won the day. In August, 1866, Mr. Abernethy, C.E., reported in favour of the scheme; in June, 1865, the Act was obtained; and in 1868 the Board of Trade advanced £22,000 on debentures, payable in seventeen years, the town of Lynn contributing £20,000. In October, 1867, the first work was begun, and in the December of that year the formation of the dock was actually commenced. The excavation was commenced in November last, and last Wednesday the Prince and Princess of Wales declared the dock open. The area of the dock at the water level, which is 26ft. from the bed, is about 6¾ acres, the length being on the northern side 590ft., and on the southern 780ft., and the width averaging 440ft. The sides of the dock are sloping, and are faced with blocks of artificial stone, made on the spot. There are seven jetties for the use of large vessels, and these jetties are connected by tramways with the railway lines that run round the dock. The capacity of the dock is put down at 50,000 tons of shipping, and vessels of 1,200 tons to 1,500 tons can obtain access at any high tide. During the excavation, which went through alluvial deposit to the Kimmeridge clay, an immense quantity of animal remains was found, among the sculls being those of the wild boar, the wolf, the tiger, the elk, and the beaver. Several specimens of Roman and Saxon pottery were discovered in the same drift, far below which are sunk the foundations of the lock, which is 30ft. deep, 200ft. long, and 50ft. wide, the walls being at the bottom as much as 12½ft. in thickness, and the end walls fully 16ft. The walls are of brick, faced with Bramley Fall millstone gritstone, which is protected by timber fenders; and the lock-gates, made on the spot, are framed in oak, and covered with Dantzic fir. Each leaf measures 29ft. in width by 31ft. in height, and is 2ft. 9in. in thickness. Mr. J. Leslie, C.E., has been the superintending engineer, Mr. W. F. Lawrence the contractor. No work of the kind could have been better done; the whole cost being about £80,000.

A GERMAN chemist, M. Kuhr, proposes a new method for marking linen. It is first saturated with a solution of 1 part of hypophosphite of soda and 2 parts of gum in 16 parts of distilled water. The linen is then ironed, and, when dry, you write upon it with a quill pen charged with a solution of 1 part of nitrate of silver and 6 parts of gum in 6 parts of distilled water.

ON THE MOULDING OF TOOTHED WHEELS.*

By MR. GEORGE L. SCOTT.

THE apparatus for moulding toothed wheels to be described in the present paper has been designed by the writer to supply the means of obtaining strictly accurate castings by machine moulding, with a portable and self-contained machine of small cost, capable of being readily and quickly applied at any part of a foundry. The accuracy and perfection of the teeth of wheels are of great practical importance in all cases of gearing, and especially where large amounts of power are transmitted by them; and it requisite that the transmission of power should be uniform and continuous through the teeth of the wheels, corresponding to the continued frictional contact of two circles rolling upon each other. To maintain this uniform and continuous action in toothed wheels, all the teeth throughout the circumference of the wheel are required to be precise duplicates of one another in form, size, and spacing; and all to be placed in a perfect circle round the centre of the wheel. Should these conditions be imperfectly carried out, the essential continuous contact will be destroyed, and a serious intermittent knocking between the teeth will be caused, leading to the fracture of the wheel, and risking a stoppage of the machinery. Any defective fitting of toothed wheels also involves a waste of driving power from the irregular shocks in transmitting the power; and as a consequence the wheel will not last so long in such a case, owing to the friction causing extra wear of the teeth.

In the earliest method of making toothed wheels, the teeth were chipped out by hand from the solid edge of the wheel, upon which they were set out and shaped to template. Subsequently, the teeth were formed on a wood model of the wheel, and moulded from this model according to the plan in general use, involving the necessity of having a separate expensive pattern for each wheel that differs in form and pitch of teeth as well as in diameter. The result has been a vast collection of toothed wheel patterns to meet the requirements of ordinary trade demands; and this stock has become so costly in the expense of construction and of the storage space occupied, that it has led to an objectionable limitation in the range of pitch of wheels, in order to reduce the extent of the stock of patterns. The use of wood patterns for entire wheels involves further the practical objection of liability to distortion, both in the general contour of the wheel and in each tooth, owing to the irregular effects of expansion and contraction in the component parts of the pattern; as well as the unavoidable risk of variation in the forms and dimensions of the several teeth, in consequence of the different finish that each receives. The uncertainty, too, attending the drawing of an unwieldy pattern from its mould, and the distortion of the pattern that occurs from its lying in damp sand for a considerable time, are additional obstacles to the manufacture of a toothed wheel from the ordinary wood models with the correctness that is desirable.

The only method of overcoming these difficulties is by employing only a small segment as the pattern, and moulding the entire toothed circumference by repetition of this small portion; employing mechanical means for lowering and raising it, and for spacing out the teeth round the circumference of the wheel so as to obtain the same certainty of accuracy throughout, as is shown by a wheel divided and cut in a machine. This process was introduced by Mr. P. R. Jackson, and carried out with the greatest accuracy; and, until the advent of his most valuable machine, it may be said that no really correct toothed wheels were cast.

The object of the wheel moulding machine forming the subject of the present paper is to extend the application of this process by the use of a portable machine, of small size and cost, that can be easily applied for moulding a toothed wheel in any part of a foundry. Having moulded one wheel, the machine can be fixed at another place for use, or be put away until required again, in the meantime leaving the foundry floor clear and in the usual condition for ordinary work. It will enable any foundry to supply with rapidity and economy of manufacture wheels possessing the absolute accuracy which results from the use of a machine.

The machine is made of two sizes, one for moulding wheels from 12in. to 5ft. diameter, and a larger size for wheels from 20in. to 12ft. diameter. The smaller machine is shown in the annexed engraving. Fig. 1 shows an end elevation of the machine, fig. 4 a side elevation, and fig. 5 a plan. A pedestal A, shown separately in fig. 2, supports a centre pin B, which has a collar to bear upon the pedestal, and is provided with a projection that fits into a recess in the top of pedestal, whereby it is prevented from turning in its socket. The spindle C is bored to fit on the centre pin B, and is turned to pass up through the rest of the apparatus, which it supports, as shown in section in fig. 6. Set screws placed in the spindle C are used to fix it firmly on the centre pin B, and this being secured in the pedestal a continuous vertical centre spindle is thus obtained. Loose collars provided with set screws and bored to fit the centre pin B are used for the purpose of elevating the apparatus above the pedestal A, in order the more readily to adapt it for moulding different breadths of wheels. One of these collars is shown at V in fig. 11, and they are of 1in., 2in., and 3in. in thickness respectively.

On the spindle C is carried the head D, shown in section in figs. 6 and 7, and in this head slide the radial arms E E, connected together at their front ends by the transverse piece F, which forms the bed for the vertical sliding ram G. The arms E E are secured to the head D in any required position by four square-headed bolts passing through slots in the arms and through ears cast on the head; these bolts, being screwed up, bind the arms and head firmly together. The spindle C, being firmly secured in the pedestal, forms a stationary centre pillar for the machine, on which the head D is free to turn; and, on the top of the spindle, is keyed the wormwheel H, from which a connection is made to the arms E by the dividing apparatus shown in figs. 1, 4, and 5. This consists of a worm I gearing into the wheel H, and the change wheels J J J, the uppermost wheel being on the worm shaft, and the lowest one keyed on the shaft K, which is carried by brackets on the arm E, and is provided with a loose collar acting as a bearing, so that the shaft may be withdrawn for altering the change wheels when required. The swing frame L carrying the change wheels is sufficient for two intermediate change wheels if required. On the shaft K is fastened a spring handle M, which fits a slot in a disc that is divided to guide the workman in the number of turns to be given to the shaft. The traversing screw O is carried by brackets on the arm E, and passes through the nut N bolted to the head D, so that, by turning the screw O by the handwheel at the end, the arms are moved in or out, to suit the varying diameters of wheels to be moulded.

On the slide bed F fits the vertical sliding ram G, which is held in by the cover R shown in section in fig. 8; and a hand screw S retains the ram in any required position. The bottom of the ram is bored to receive the angle bracket T, which is secured in it by steady pins; and to this is attached the segment pattern U of the wheel teeth to be moulded. The ram is moved up or down by a handwheel Y, having a worm gearing into a wormwheel, on the shaft of which is a pulley Z; from this pulley, two chains pass in opposite directions, the one being secured to the bottom of the ram, and the other to the top, and kept always tight by means of two lock nuts. An adjustable brass collar W is fitted on the ram for indicating to the moulder when the ram is sufficiently lowered. An eyebolt is fixed on the top of the centre pillar C of the machine, for attaching the foundry crane in order to remove the machine.

The process of moulding a wheel with this machine is as follows:—A core box for the arms of the wheel is first prepared, and also two radial boards for strickling the form of the top and bottom of the wheel in the sand, which are shaped to the profiles of the face and back of the wheel. The top board P, shown in fig. 11, has on its lower edge the profile of the back of the wheel; and the bottom board Q has also, on its upper edge, the counterpart profile of the back of the wheel, and, on its lower edge, the profile of the face. A pattern is also made of a segment of the toothed rim of the wheel, consisting of two teeth only, which permits of moulding one space at a time.

A secure and steady foundation for the moulding machine is obtained by sinking in the sand of the foundry floor in the desired situation the pedestal of the machine, which is bolted to a cast-iron base plate, about 4ft. square; sand is then rammed solidly upon it, and the pedestal levelled so as to be truly vertical. Another form of pedestal is shown in fig. 3, which is used for fixing in the sand without a baseplate. The top of the pedestal is placed about 15in. below the floor level, this distance determining the greatest breadth of wheel that can be moulded. The centre pin B of the machine is then placed in the socket of the pedestal for the purpose of forming the mould for the bed of the wheel, and also to mould the top box or other arrangement used to cover the mould for casting; the rest of the machine being laid aside for the present.

In fig. 11 is shown the loose collar V which is placed upon the centre pin B, of such thickness that its upper face is the same depth below the floor level as the breadth of the rim of the wheel to be moulded; so that the back of the wheel is level with the floor for convenience of fitting the top box on. This lower collar V is fixed by a set screw, and an upper loose collar X is also fitted on the centre pin V by a set screw, with its upper face at the same height above the collar V as the breadth of the rim of the wheel; the lower collar thus exactly indicates the level of the bed and face of the wheel, and the upper collar that of the back of the wheel. The hole is then filled up with sand to the level of the upper collar; and the iron trammel carrying the top board P is placed upon the spindle B, and worked round upon the collar X, forming a mould of the back of the wheel, which is then sprinkled with parting sand to form the parting for the top box. An ordinary top box or other sufficient covering is then placed on, and rammed up with sand; and the box is then staked in the ordinary manner, for the purpose of marking its correct position, relatively to the bottom part of the wheel, by stakes driven into the sand, and fitting by the side of corresponding ears upon the top box. The top box is then lifted off, carrying with it the impression of the back of the wheel; which impression is finished by turning the box over, and strickling it again with the second trammel that carries the bottom board Q. A centre is provided in the top box for this trammel by means of a loose collar, in which are two bolts that pass through the top box and are fastened across the bars of the box. This loose collar fits the spindle B, and is drawn from it with the top box, thus fixing a strictly accurate centre. By this arrangement, the centering collar can be readily fixed upon any ordinary top box, giving strict accuracy in the moulding, without requiring any special boxes for the purpose.

For forming the bed of the mould, the top collar X is then removed, and the mould being dug out to the level of the bottom collar V, the sand is strickled with the bottom radial board Q, worked round upon the bottom collar V. This forms the mould for the lower and outer faces of the teeth, and finishes the mould ready to receive the teeth and the cores for the arms; and, as both the back and the face of the wheel have been struck from the same trammel and the same centre, perfect accuracy is ensured in the wheel.

The segmental pattern of the teeth U, figs. 9 and 10, is then fitted truly square and central, and secured by screws upon the angle bracket T of the vertical sliding ram G, fig. 4. The upper portion of the machine is then placed upon the spindle B, the trammel having been removed; and the fixing screws in the spindle are screwed up to maintain the central axis continuous through the machine. The segmental pattern U is adjusted by the traversing screw O, fig. 5, to the correct radius of the wheel, measuring from the top of the tooth to the centre of the machine. The ram G is then lowered to the level of the bed of the wheel, and secured at that point by the locking screw S; and the brass collar W is adjusted on the ram and fixed by a set screw, to ensure the ram always stopping at the same level when lowered for moulding each successive tooth. The locking screw S prevents the ram rising from the pressure of ramming the sand. One space of the wheel teeth is then moulded by ramming sand in the space left between the pattern and the edge of the mould previously formed by the strickle board. The locking screw S being then released, the ram carrying the pattern is raised clear of the mould, and is then traversed round through the exact distance of the pitch of the wheel, by means of the dividing handle and the change wheels previously arranged for the required pitch. The segmental pattern is then again lowered, and a second space moulded as before.

When all the teeth have been moulded, the fixing screws of the central spindle are released, and the whole machine is then lifted away by the foundry crane laying hold of the eye-bolt on the top of the spindle, leaving the mould entirely clear to receive the cores for the arms and boss. The hole in the top of the pedestal is fitted with a cover to keep out the sand, and is then covered over with sand, which protects the pedestal against the action of

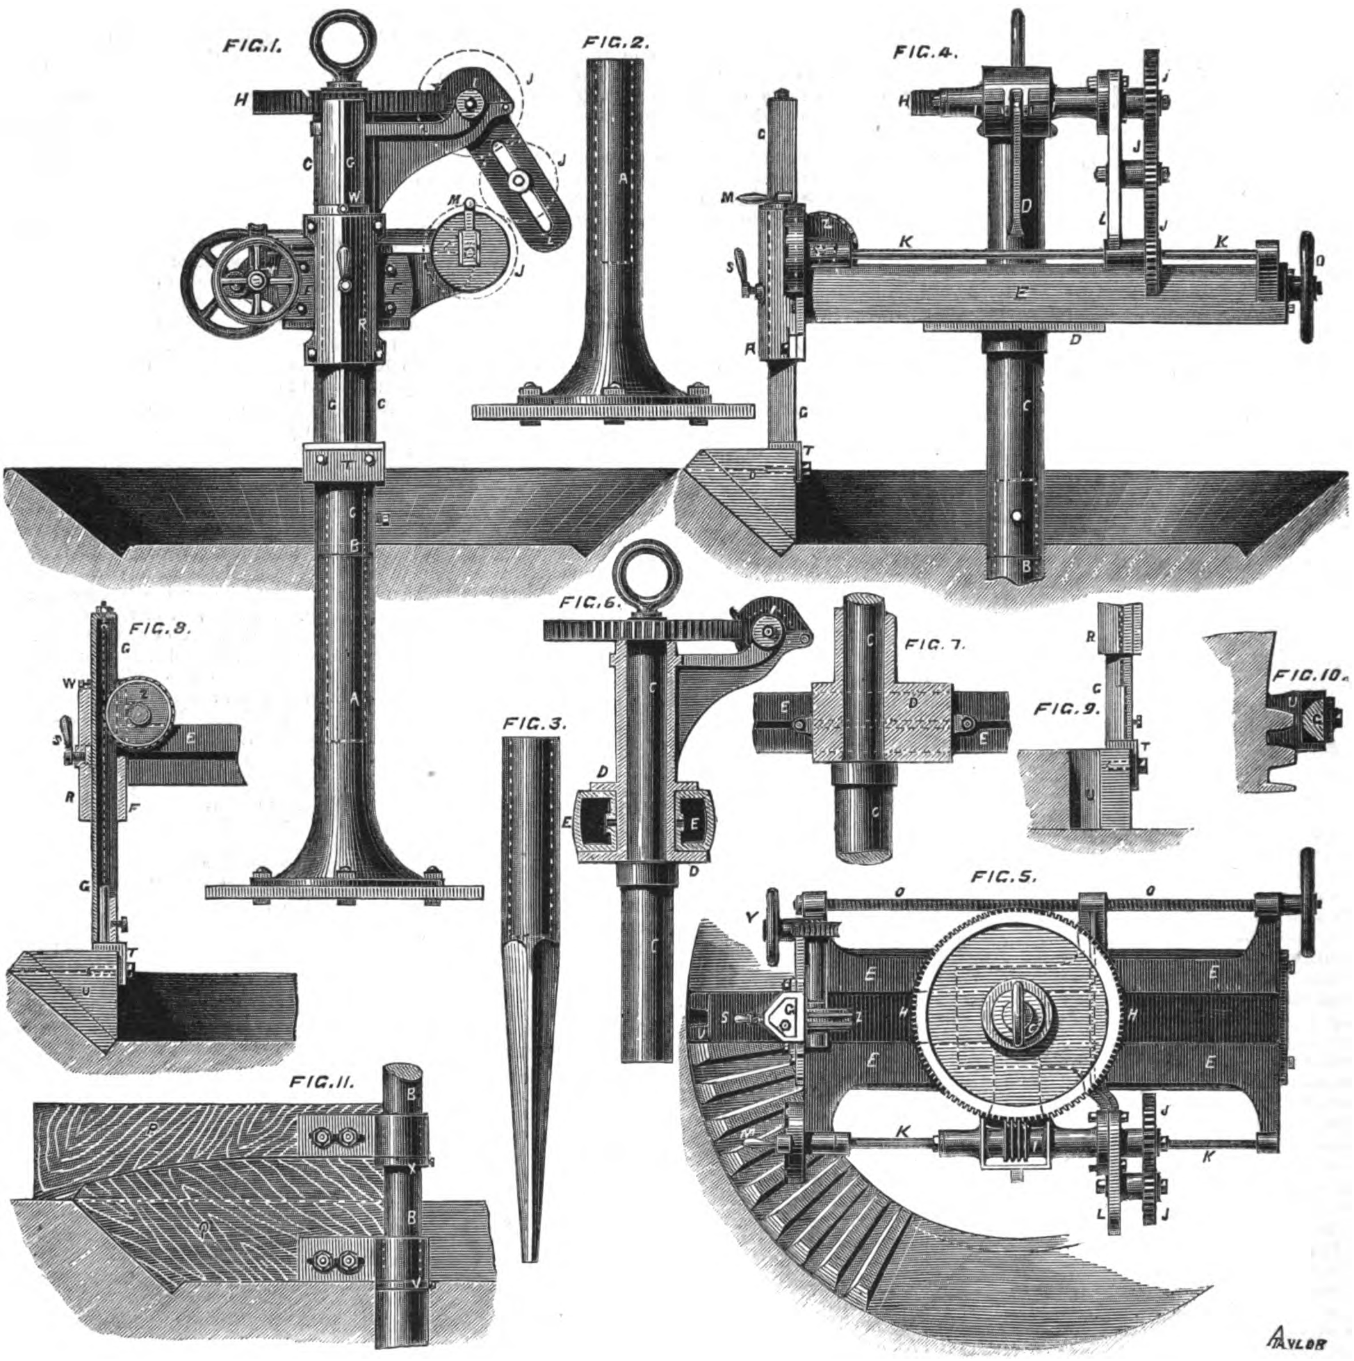
MACHINE FOR MOULDING TOOTHED WHEELS.

BY MR. G. L. SCOTT.



the hot metal. The centre core for the wheel is adjusted as usual from the circumference, and the cores for the arms are set to their places by means of wood gauges showing the thickness of the arms and rim. The top box is then put on to cover the mould, being placed in its correct position by the stakes previously mentioned; the runner is then formed, the box duly weighted, and the whole is ready for casting.

This mode of moulding wheels gives the certainty of strict accuracy and excellent finish throughout. The trammel revolving on a secure centre ensures a true circle in the circumference of the teeth; the dividing arrangement ensures the correct relative position of all the teeth; the mode of raising the tooth pattern ensures a gradual steady withdrawal from the sand, whereby the mould is left perfectly finished; the tooth pattern, having but one space from which the whole number of teeth are moulded in succession, produces each tooth an exact duplicate of all the others; and the arrangement for forming the mould and the top box from the same centre produces so good a joint, that the occurrence of any fin on the edge of the teeth is prevented. This great superiority in the finish of the wheels moulded by the machine, as compared with hand-moulding from wheel patterns, is accompanied by a very important economy, saving the heavy outlay required for a large stock of costly wheel patterns; thus, in the case of a wheel of 6ft. diameter and 12in. breadth, instead of a complete wheel pattern costing about £10, the whole expense required with the machine for the tooth segment, core box, and strickling boards, will be only about 15s.

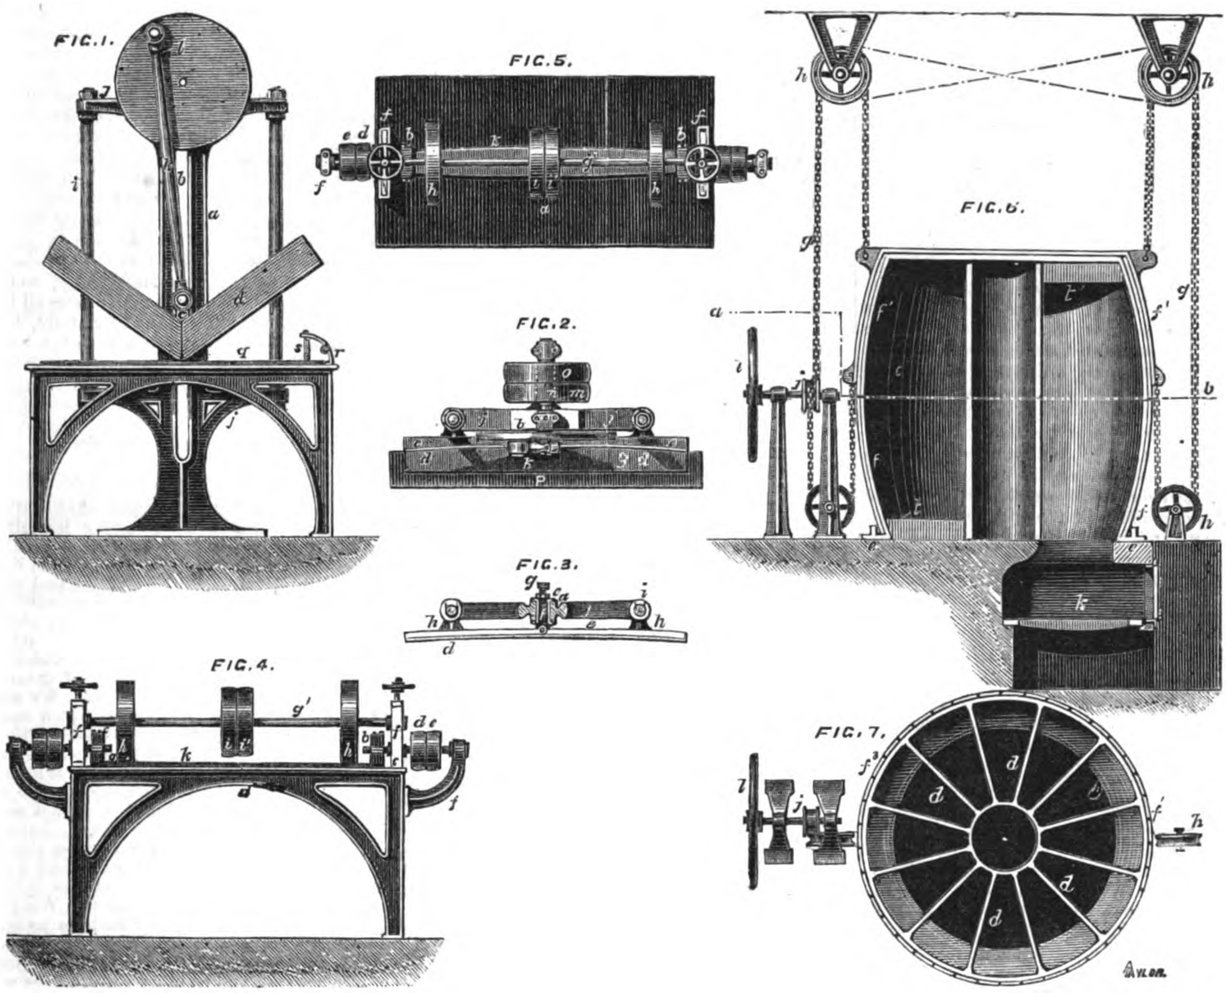
The moulding machine now described has the advantages of great compactness and convenience for use, as it occupies but little room; and being used in the foundry floor, it effects a great saving in the expensive item of boxes. A special feature of advantage is the portability of the machine, which is a point of great importance; and, as a consequence, one machine is made to do the work of several, by simply fixing two, three, or more pedestals in different parts of the foundry floor, upon any one of which the machine can be quickly and readily placed for moulding a wheel; whilst those pedestals that are not required at the time are simply covered with sand, leaving the floor in its usual state, clear for other work. By this means, the moulding of more than one wheel may be in progress at the same time, with the cost of only one machine in the foundry.

An important practical advantage obtained by machine moulding is the power of manufacturing wheels with an unlimited variety of dimensions, pitch, and forms of teeth, so as to meet exactly the requirements of any case that may occur; thereby avoiding the serious obstacles so frequently experienced of having to modify the intended wheel, in order to suit some existing range of patterns and obviate the serious cost and the delay attending the preparation of a new complete pattern.

As an example of the rapidity of moulding large wheels by means of this machine, it may be mentioned that a bevel wheel of 9ft. diameter and 12in. breadth, weighing 3 tons, was moulded and cast within four days from the time of the order being given at the North Moor Foundry, Oldham; and, in another case, at Messrs. Buckley and Taylor's, Oldham, a shrouded bevel wheel of 6ft. diameter and 11in. breadth was moulded in twenty-four hours by two men; and a spur wheel of 9ft. diameter and 8in. breadth, weighing 2 tons, was also moulded in twenty-four hours by two men.

CASK-MAKING MACHINERY.

BY MR. JOHN REID.



REID'S CASK-MAKING MACHINERY.

Mr. JOHN REID, of Glasgow, has recently patented some machinery for cask-making, which forms the subject of the accompanying illustration, for which, with the following description, we are indebted to the "Brewers' Journal." The invention includes improvements in machinery for cutting staves, for bending and heating them, and for "croessing" and dressing their ends. It also embodies an improved method of forming the ends of barrels and also of trussing them. In our engraving, fig. 1 is a front elevation of a guillotine cutting machine, for shaping the staves of casks. Fig. 2 is a plan, and fig. 3 a horizontal section of the same machine, the latter view showing the reciprocating frame and guides. The machine consists of a standard *a*, having a vertical opening *b* formed in it, in which the guide block *c* slides. The cutting or shaping knives *d* are fastened to a curved frame *e*, formed in two parts and hinged at the centre to a block *f*, which slides horizontally in the guide block *c*. The object here is to allow of the adjustment of the cutting knives *d* to any required curve by means of the set screw *g*. Guide brackets *h h* are cast on or attached to the curved frame *e*, and slide upon the rods *i i*, which are fitted to the bracket *j*, cast on the main standard *a*. The knives *d* are actuated by a connecting rod *k*, which is attached at one end of a disc *l*, and at the other end to the guide block *c*. The disc *l* is keyed on to the shaft *m* and rotated by means of a belt actuating the fast pulley *n*; *o* is a loose pulley for throwing the machine out of action.

In cutting the staves, they are placed upon the table *p*, as shown at *q*, figs. 1 and 2; and when one edge has been cut by the descent of the guillotine knife *d*, the stave *q* is turned, and the other edge is cut by the next descent of the knife. To facilitate the production of staves, two of these machines may be used, placed one at the end of the other, and with their front sides turned in opposite directions. In operating with this arrangement, a doubled-armed lever or "kicker" *r*, fig. 1, is used to push the stave from one machine to the other. The "kicker" is so placed that, as the guillotine descends, and while cutting one edge of the stave, the upper arm of the "kicker" is depressed by the curved frame, and compresses the spiral spring *s*, which is instantly relieved when the stave is cut. This causes the "kicker" to rotate and push the stave on to the table of the next machine, where the second edge is cut without the stave being turned. The cutting table *p* is adjusted by means of set screws, so that the edges of the staves may be cut to suit the diameter of the cask which they are to form.

Fig. 4 is a front elevation, and fig. 5 a plan of a "croessing" and dressing machine upon Mr. Reid's plan. The staves are placed upon the table *a*; *b* are the discs in which the cutters *c* are fitted; *d* and *e* are fast and loose pulleys by which the discs *b* are operated; *f f* are brackets fixed to the table *a*, in which the cutter spindles *g* and the feed roller shaft g^1 are carried; *h h* are the feed rollers which are operated by the fast and loose pulleys $i\ i^1$. The staves are placed on the table *a*, as shown at *k*, and are drawn through the machine by the feed rollers *h h*. As the distance between the table *a* and the cutters *c* is preserved uniform for all the staves which are to be used in one description of cask, the grooves in the staves into which the ends will fit are cut more or less deep according to the thickness of the staves. The thickness between the bottom of the groove and the outside of the stave will, however, be the same in all the staves. The inequalities in the thickness of the staves of undressed barrels will thus appear in its interior instead of its exterior, which will have a more finished appearance. The ends of the staves are dressed at the same time that the "croessing" operation is performed. This operation is effected by placing a circular saw on each of the cutter spindles *g*, or on spindles carried under the tables, so as to cut the staves to a uniform length as they pass through the machine.

Mr. Reid's apparatus for heating and bending the staves is shown at figs. 6 and 7, the latter being a sectional view on the line *a b*. This apparatus consists of a chamber *c*, which is constructed in the form of a barrel, and divided radially into vertical passages by the partitions *d*. A T-flange runs round the bottom end of the chamber *c*, and forms a groove *e*, in which the ends of the staves *f* are placed. A cover f^1 is raised or lowered by the chains *g* passing over the pulleys *h*, and actuated by the hand wheel *i* and chain *j*. The chamber is heated to the required temperature by hot air supplied from the furnace *k*, the vertical passages communicating alternately at top and bottom by the openings *l*, fig. 6 forming a flue through which the heated air and products of combustion pass on their way to the chimney. In using this apparatus, the cover f^1 is raised by means of the hand wheel *i*, sufficiently high to allow of one end of the staves being inserted in the annular space between the cover and the chamber *c* and the bottom end into the groove *e*. The cover is then lowered, and the staves *f* are pressed close to the sides of the heated chamber. When the staves are sufficiently heated and bent, they are removed, and the apparatus again filled with staves. We reserve our description of Mr. Reid's machinery for forming the ends of barrels, and of his trussing machine, until our next number.

QUALITY OF THE CITY GAS.

Dr. LETHEBY, the chief gas examiner to the Board of Trade, has reported on the quality of the gas supplied to the City during the months of April, May, and June; and it was found that, when tested in accordance with the provisions of the statute, the maximum, minimum, and average illuminating power in standard sperm candles of the gas of the three City companies had been respectively as follows:—The City of London Gaslight Company, 15·73, 14·10, and 14·87; the Chartered Company, 15·90, 14·10, and 14·98; and the Great Central Company, 15·62, 14·06, and 14·72. With respect to the purity of the gas, the examiner reported that ammonia had been constantly present in the Chartered and Great Central supply, but that the gas of all the companies had been quite free from sulphuretted hydrogen. The following were the maximum, minimum, and average proportions of grains of sulphur in 100 cubic feet of gas:—City of London Company, 23·40, 7·02, and 17; Chartered Company, 21·45, 10·75, and 16·86; and Great Central Company, 26·72, 4·16, and 11·58. Those results indicated a remarkable range in the proportions of sulphur, the minimum proportions being altogether unusual.

GOLD CURRENCY.

THE Master of the Mint and the late master of the Calcutta Mint have reported to the Chancellor of the Exchequer upon the question of the mintage necessary to cover the expenses of establishing and maintaining the gold currency. The gold coinage in circulation in the United Kingdom is generally estimated at about 80 millions sterling, 68-80ths being sovereigns and 12-80ths half-sovereigns. An estimated annual coinage of about 10 millions would be made up of 4 millions of first coinage and 6 millions of renewal. The cost at which a sovereign or half-sovereign is produced may be safely taken at about a halfpenny. By wear, sovereigns fall below the legal weight after a circulation of eighteen years, and half-sovereigns in ten years. Mr. Jevons calculates the annual loss by wear on 100 sovereigns at 8·371d.; on our present mixed circulation of sovereigns and half-sovereigns the annual loss is calculated at £35,000. Some coins drop out of circulation annually by shipwrecks, fires, melting, losses, &c., and, on the other hand, it is estimated that there are about 30 million sovereigns in circulation in foreign countries, part of which may be returned to the United Kingdom for renewal when they become light. The result of the whole calculation is that for our circulation of 68 million sovereigns and 12 million half-sovereigns, an endowment of £1 13s. 6d. for every £100 would suffice for the permanent maintenance of the coin, the first construction, and all future restoration. These results are based upon the mere bullion by itself, and are quite independent of all other considerations.

DYEING AND PRINTING.

AT the present time, sumach is much used in dyeing and printing, in order to cause other dyes to take better on the fabrics or fibres of materials to be dyed or printed. According to an invention lately patented by Mr. J. L. Norton, of Bell Sauvage-yard, Ludgate-hill (whose name is well known in connection with the Abyssinian tube well), an extract of the bark of the hemlock tree is substituted for the sumach, the desired result being thus more effectually and economically attained. The following are the details of the methods by which Mr. Norton operates in order to obtain a number of different colours:—

To dye 20lb. weight of cotton a magenta colour, take 3lb. of Miller's extract of hemlock bark as imported from Canada, and boil it with 20 gallons of water, and then lay the cotton in the liquid for a night. In the morning, add 3 pints of red cotton spirits diluted with 20 gallons of warm water, and work afterwards the cotton in this for 50 minutes. Then bring it out and wash twice with cold water, and afterwards with warm water. Then take 20 gallons of fresh water heated to 160deg., and put 2 pints roseine solution into it, and work the cotton in this liquor till the colour is full enough. Wash the cotton and dry it.

To dye a primula colour, proceed as before, only using a solution of Hoffman's violet instead of roseine, and work at the same temperature (160deg.). A bluer tint may be obtained by increasing the heat, or a redder by lessening it.

To dye a lavender colour, take of extract of hemlock bark 1½lb. to 20lb. of cotton, and work the cotton in the extract diluted with 20 gallons of water for half-an-hour. Rinse and wash in cold water, and then in warm. Take of red cotton spirits 1 pint diluted with 20 gallons of warm water, and work the cotton in it for 15 minutes, then wash in two warm waters. Afterwards work the material in a bath consisting of 1 pint of Nicholson's No. 2 blue solution, with one gill of nitric acid at about 100deg. Wash the cotton and dry it.

To dye a green colour, prepare with 4lb. of extract of hemlock bark mixed with 20 gallons of water. Lay the cotton in this for 1½ hour at a boiling heat; then prepare a bath with 20 gallons of cold water and 2¼ pints of double muriate of tin, and work in this half-an-hour. Wring the cotton out and wash off well to kill the strong acid. Afterwards take 20 gallons of water at a temperature of 170deg. or 180deg., and put into it 1 pint or nearly so of iodine green paste diluted with 1 gill of methylated spirits; if a yellow shade is required add a little picric acid. Work the material in this for about 20 minutes, then wash and dry it.

To dye a gold colour, prepare with ½lb. of extract and 1lb. turmeric dissolved in 2 gallons of water. Work at a heat of about 90deg., then cool down and add ½ gill nitric acid. If the colour is not red enough, add a little annatto; if not deep enough, repeat until the shade required is obtained. To dye black, take 4½lb. of extract of hemlock bark and boil it with 20 gallons of water, and then lay the cotton in this liquid for a night. In the morning take it out and put it into a cold lime water bath of 4deg., and work in this for 10 minutes. Wring out and sodden with 15 gallons of old sumach liquor, 1½lb. of copperas, and 2 gallons of urine. Work it in this for 15 minutes, wring out, and again put it into the lime liquor and work in it for 10 minutes, and then wring out. Afterwards scald 6lb. of chipped logwood with 15 gallons of boiling water, and work in this for 20 minutes, and then give the cotton 3 turns in 15 gallons of cold water, in which 1lb. of copperas has been dissolved. Soap it with 1lb. of soap in 20 gallons of warm water, and wash off in cold water, and dry.

To dye brown, proceed as above, only with 4lb. of the extract, and in the morning take the cotton out and work it for 30 minutes in 20 gallons of cold water, to which add 2¼ pints of red cotton spirits. Then wash off in two cold and one warm waters. Then scald 7lb. of chipped logwood with 15 gallons of boiling water, and let it cool a little, and then work the cotton in it for 30 minutes. Take the cotton out and add 1lb. of alum to the bath, and work the cotton again for the shade required. Wash off in cold water, and dry.

By red cotton spirits is meant a compound of about 2 parts of aquafortis to 1 pint spirit of salts, to which block tin is added for the purpose of killing it before using. The quantities directed to be used of the several aniline dyes are applicable to the usual commercial strengths.

TELEGRAPHY IN THE RIVER PLATE.

THE first public telegraph which has been constructed by the Government of Buenos Ayres was opened on May 4. Cards were issued jointly by the President of the Argentine Republic, Don Domingo F. Sarmiento, and the Governor of Buenos Ayres, Don Emilio Castro. Many of the principal native and foreign residents availed themselves of the invitations. Two Morse instruments (by Siemens Brothers), placed in the drawing-room, worked direct with the main line, and from 2 p.m. to 4 p.m. about 100 congratulatory despatches were transmitted. The President made a speech, in which he said, "The time may not be far distant when the telegraph will unite South America to Europe." The telegraph passes westerly from Buenos Ayres for 100 kilometres, on the Government railway, then northerly for 300 kilometres, crossing several large rivers to San Nicolas de los Arroyos and Rosario de Sante Fé, two ports on the Parana, to which the Liverpool line of steamers can pass. The total length of the line is 405 kilometres of double conductors, being the greatest distance made in South America by one administration. The President has recently contracted for the construction of 800 miles of telegraph, commencing at Rosario, to proceed northward. The tariff of the Government telegraph is, for a simple message transmitted under 100 miles, 1s. 8d.; from 100 to 200 miles, 3s. 4d.; and above 200 miles, 5s. The Congress of the nation was opened on May 5, and, by the President's desire, his speech, consisting of 5,020 words in Spanish, was telegraphed to Rosario, and published there the same afternoon.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

THE thirty-fourth half-yearly meeting of members of the above Society was held at the City Terminus Hotel, on the 3rd inst. It was fairly but not fully attended, and Mr. Joseph Newton, president, occupied the chair. Mr. Welsh (of Messrs. Ravenhill and Salkeld's), and Mr. Hughes (of Messrs. Burton and Waller's), were elected as ordinary associates, and three new committeemen —Messrs. Bullough, Sherburn, and Ferguson— were appointed. Afterwards, the auditors—Mr. Edmonds and Mr. Bullough—submitted their report and balance sheet of the last half-year. From these official statements it appears that the numerical and financial condition of the Institution is rapidly improving. No less than twenty-five new members have been enrolled since the January meeting, whilst the special and working funds have grown considerably in the same period. The Association now numbers 210 members of both classes, honorary and ordinary, its general fund amounts to £481 15s. 11d.; the superannuation fund equals £1,014 17s. 4d.; and the widows and orphan's assistance fund is £15 4s. The grand total of moneys invested or in hand for all purposes is, therefore, £1,511 17s. 2d. After some slight discussion, the report and balance sheet were unanimously accepted, and the auditors received the usual vote of thanks. Subsequently, Mr. Walker, secretary, put forward a proposition for the establishment of a monthly publication, in connection with the Institution, and to be designated the "Journal of the Association of Foremen Engineers." This, it was suggested, should resemble the "Journal of the Society of Arts," and contain reports, either in full or in part, of the proceedings of each association of the kind indicated by its title in the United Kingdom. The Chairman warmly advocated the scheme, and entered into a lengthened explanation of his own views and anticipations in regard to it. Practically and statistically he demonstrated that such a publication must be successful and of great use to the associa-of London, Leeds, and Manchester, and so, no doubt, it would, if his calculations are all based on sound data. The members generally, however, appeared to be less sanguine than the chairman, and Mr. Walker's proposition, after gaining faint support from them, was adjourned for further consideration on a future day.

ON THE STEAM PIPES OF LOCOMOTIVES.

IN a recent impression, we published a letter from a correspondent, who, signing himself "Student," wrote modestly, as a student should. He stated that the locomotives on a certain line were fitted with steam pipes of 2·3in. internal diameter, and very plainly hinting that he considered these pipes too small, he asked our readers whether he was right or wrong in his conclusion. He has received two replies to the same effect, which will be found in another place, and one of these at least deserves some notice at our hands. We allude to the letter written by Mr. Poole, which contains a very grave attack on the professional abilities of the gentleman who designed the engines in question. We happen to know something of these locomotives and of their performances, although we are not acquainted, and for the present do not care to be acquainted with the designer's name. But even did we know nothing more of the engines than "Student" has told us, we should still know enough to satisfy us that Mr. Poole's accusations of incompetency are not justified by the facts. Whether Mr. Poole is or is not an engineer we have no means of knowing, but we do know, from his own letter, that he has had, no practical experience in the designing of locomotives; and no other acquaintance with the fact that the proper area of steam pipes has been decided long since by experiments than the information derived from Professor Rankine's work, which he quotes. As the questions raised possess some interest, and have a rather close connection with the flow of elastic fluids through orifices—a matter treated of in our last impression—we purpose here to say a few words which may tend to enlighten Mr. Poole, and possibly remove the impression which his words might otherwise convey.

Lest we should be mistaken in any way, we shall begin by stating that the steam pipes in question are unquestionably too small; but paradoxical as it may appear, we argue from this fact that the gentleman who designed them knew rather too much than too little about locomotive engines. If Mr. Poole had only known half as much, he would, we fancy, have eliminated certain very uncivil sentences from his letter. As we have before stated, we know nothing of the designer of the engines under consideration; but certain broad facts stand out prominently in "Student's" letter, and one or two of these are so suggestive that our correspondents might well have stopped to ask their meaning before going on to criticize in a very hasty and uncourteous spirit. One of the first points which will strike the thoughtful reader of the entire correspondence is the singular and abnormal diameter of the pipes criticized. Why should a pipe, the diameter of which cannot be stated without the use of a decimal, be used by a man who, according to Mr. Poole, works only by "rule of thumb?" Why not use a 2¼in. or a 2½in. pipe instead of a pipe 2·3in. in diameter, corresponding pretty accurately to a sectional area of 4in.? Obviously, there should be some reason for this. If it be madness, there is at least method in it; and at the risk of astonishing Mr. Poole, we may say that there are very excellent reasons for adopting this dimension of 2·3in. What these reasons are we shall now proceed to show.

The foundation of all knowledge is experience, and experience is especially valuable in dealing with the locomotive. It is very well to lay down certain premises, and, arguing from them, insist that certain dimensions must be right and certain others must be wrong; but it is obvious that if the premises are false the remaining links of the logical chain must be untrue also. Theoretically, a steam pipe 2·3in. diameter is too small, but in practice it

IMPROVED PLOUGH.

BY MR. A. GUTHRIE.

FIG. 1.

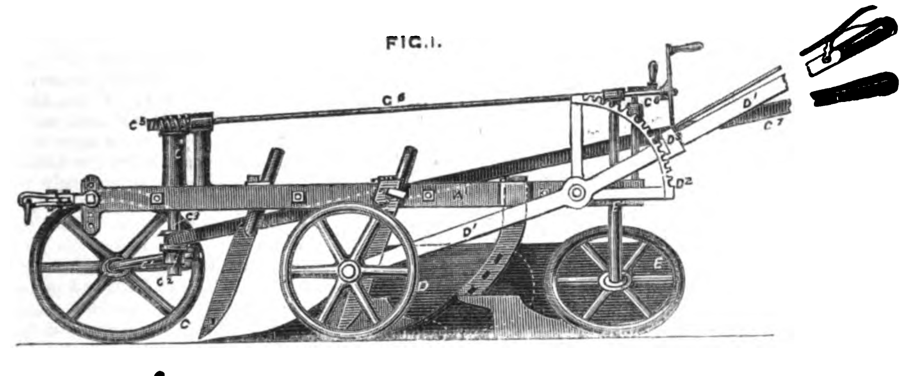


FIG. 2.

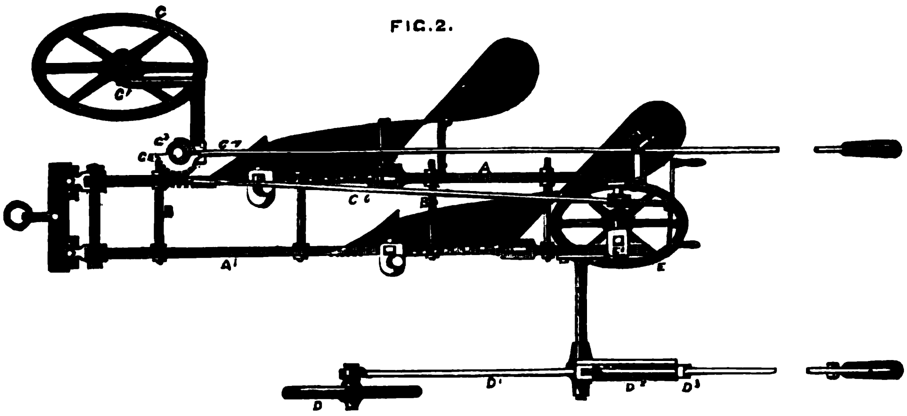

has been found that no advantage whatever follows on adopting a larger opening of regulator than one which will give an area of four square inches for a pair of 15in. cylinders, or 1-88th of the aggregate area of the two pistons. The only comprehensive and able paper on the subject with which we are acquainted is to be found in Mr. D. K. Clark's "Railway Machinery," and particulars are there given of numerous experiments carried out on the Caledonian Railway, which conclusively prove that no benefit is derived from increasing the area of regulator opening beyond four square inches. It is naturally to be concluded that as the quantity of steam passed by a pipe is measured by its smallest part, no advantage will be derived from making the steam pipe larger than the regulator. It is evident that the designer of the engines alluded to by "Student" took the results of Mr. Clark's experiments as conclusive, and adopted the 4in. of area stated by Mr. Clark to be as good as any other. We think that Mr. Poole will now begin to see that he has been just a little too hasty in charging a gentleman of whom he knows nothing with gross incompetence. Far from manifesting ignorance on the part of the designer, the engines in question prove that their designer had mastered the results of experiment, and had acted in tolerably close accordance with the rules laid down by one of the best authorities on the subject of locomotive construction.

Having said so much in favour of the engines in question, it is now time to justify the statement contained in a preceding paragraph. We think that 4in. of area is too little for a steam pipe intended to supply a pair of 16½in. cylinders, because it approaches the minimum dimension too closely. It, in a word, runs things too fine. A powerful shunting engine was at one time, and may be still, worked on the Great Northern Railway with a steam pipe only 1in. in diameter. The engine performed satisfactorily; but we do not, therefore, recommend all locomotive engineers to use 1in. steam pipes. The adoption of a 2·3in. steam pipe is the result of a too rigid interpretation of the results of Mr. Clark's experiments; but it is not, as Mr. Poole would have us believe, any evidence of gross incapacity on the part of the adopter.

When our correspondent speaks of "increased coal bills," we begin to doubt the soundness of his own attainments more than ever. The only effect which can follow on the use of too small a steam pipe, is that the pressure in the valve chest will be less than that in the boiler; but it does not ensue as a consequence that the consumption of coal per mile will be materially augmented. The result may, indeed, be the very reverse. Many drivers know by experience that their engines do better, and burn less coal, when they run with the regulator partially closed, than when it is kept full open. Theoretically, this ought not to be the case. The regulator should be full open at all times when the engine is running, the speed being regulated by the position of the links; but, in practice, many engines at all times, and all engines, when working with dirty water, prime continuously, to a greater or less extent, if the regulator is kept full open. When the steam is throttled it finds its way dry and "lively" to the cylinders; when it is wet it moves sluggishly. If the steam is dry, the difference in pressure between the cylinder and boiler may, at thirty miles an hour or so, amount to 16 per cent.; of which loss not more than one-fourth is due to the resistance of the steam pipe and regulator, the remainder being wasted in the ports. If the steam is wet, the loss may rise to as much as 40 per cent. From this it is easy to see that a large regulator opening and a big steam pipe, by inducing priming even in a very moderate degree, may actually entail a loss of pressure which would not be experienced if smaller pipes were used. We need scarcely add that the evil effects of the use of damp steam would not end with a diminished valve-chest pressure; we should have in addition a cool cylinder, a sluggish exhaust, an augmented back pressure, and a heavy consumption of fuel, which means a heavy fire and an increased tendency to priming.

As a general rule, the diameter of a steam pipe cannot be too great, and the area of the regulator should not be less than ten square inches for a pair of 16½in. cylinders. But to this rule there are numerous exceptions. The adoption, for instance, of a 10in. regulator and a 16in. pipe, that is to say, 4½in. diameter, can only be justifiable when the engine has ample steam room, and is worked with clean water. If the engine is a heavy primer, either because the water is dirty, or the design of the boiler bad, then large steam pipes and regulators will do more harm than good, unless they are managed by men who never open the latter fully.—" The Engineer."

APPROPRIATION OF TAXES.

WE last week extracted a few figures from a paper by Mr. Stokes, which showed the war expenditure of various nations and states. We now append, from the same source, a statement showing how the taxes are appropriated in several countries. The revenue of Great Britain is the largest in the known world, yet, with all our wealth, a smaller proportion of it is spent upon the Government itself than in other European States, as the following comparison shows :—

	Per cent.		Per cent.		Per cent.	
In Prussia, they spend	26	on war forces,	17	on debt,	57	on the State.
" Russia "	34	"	12	"	54	"
" Spain "	25	"	18	"	57	"
" Portugal "	26	"	23	"	51	"
" Austria "	29	"	27	"	44	"
" France "	26	"	31	"	43	"
" Great Britain "	43	"	42	"	15	"

From this statement, Mr. Stokes deduces that while those six states spend a large proportion of their national income upon the Government, we spend 85 per cent. of ours on debt and war. There is truly no similar extravagance in the known world. Even China, though but imperfectly civilized, manages the government of 660 millions of mankind with about sixty millions of revenue—that is, about 3s. 4d. per head per annum—but we, with our superior enlightenment, contrive to extract from the pockets of the people no less a sum than £2 5s. per head, for precisely the same work.

GUTHRIE'S IMPROVED PLOUGH.

THE invention illustrated in the annexed engraving relates to improvements in that class of ploughs in which two or more furrows are turned simultaneously, and the whole weight of the implement is supported upon wheels. The improvements have been patented by Mr. Alexander Guthrie, of Craigs, Forfar. The body of the plough consists of a rectangular frame, to which the coulters and mouldboards are fastened in such a manner that they can be readily shifted in position to form any required breadth of furrow. The guiding and landside wheels are attached to this frame by means of adjustable levers, which will admit of the coulters and mouldboards being raised or lowered and guided so as to form two or more furrows simultaneously of uniform breadth and depth. These levers are under the control of the attendant, and can be instantly shifted to suit the varying nature of the soil without the necessity of stopping the horses. The axle of the hind or trailing wheel is attached by a movable bracket to the frame. This bracket is so formed that the trailing wheel can readily be shifted to a greater or less angle, so as to have more power over the mouldboards.

In our engraving, we have shown these improvements as applied to a two-furrow plough, fig. 1 being a side elevation, and fig. 2 a plan of the same. The rectangular frame forming the body of the plough is composed of two beams A A^1 of malleable iron, connected together by transverse screw bolts B B. This frame is carried by three round-rimmed wheels C, D and E. The leading or guiding wheel C has for its axle the extremity of a cranked arm C^1, which is attached to a sliding boss or clutch C^2. This clutch slides upon an upright spindle C^3, which is carried by the fixed bracket C^4 on the beam A. Keyed to the top of this spindle C^3 is a toothed sector C^5, which is actuated by a worm on the shaft C^6. Fitted to the rear end of this shaft, which extends beyond the back of the frame, is a crank or hand wheel which is used for the purpose of guiding or turning the plough and altering or straightening the furrow without stopping the plough. The width of the furrow is regulated by turning the nuts on the transverse screw bolts B B, which connect the two sides of the frame, and thus contracting or increasing the space between the sides. The cranked arm C^1 can also be shifted outwards or inwards, to or from the frame, to suit various widths of furrow.

The guiding or leading wheel C is raised or lowered by means of a forked hand lever C^7, which is adjusted and held securely in its place by a vertical screw C^8 attached by a swivel joint, and turning in a tapped bracket bearing projecting from the frame. By turning this screw C^8 by means of a winch handle keyed thereto, the depth of the off-side furrow will be regulated. The land-side wheel D is carried by a hand lever D^1 pivoted to a projection on the beam A^1, to which projection is also affixed a notched quadrant D^2. This wheel D, when lowered or raised, regulates the depth of the land-side furrow. The lever D^1 is adjusted and held in position by means of a sliding spring catch D^3 which it carries, engaging with the notched quadrant D^2. The hind or trailing wheel E is carried by an inclined spindle attached to the movable bracket E^1. This spindle is acted on by a half-round bead or strip attached to the frame, and forming a fulcrum for the bracket to rock upon. By screwing up either of the clamping bolts of the bracket, the wheel is made to take less or more of an angle to the vertical, so as to give power to the mouldboards to press up the furrow.

The mode of working the plough is as follows: —In cutting the first set of furrows, the leading wheel C will be raised to the same level as the land wheel D, viz., the depth of the furrow above the "sock." The width of the furrows being determined, the coulters and mouldboards are set to correspond thereto by means of the nuts on the transverse screw bolts B. The first set of furrows are now cut, at the end of which the leading wheel C and land wheel D are depressed by means of their respective hand levers, so as to raise the mould-

boards out of the ground. On returning to cut a second set, as the leading wheel will now run in the furrow nearest to those about to be cut, it is lowered to the same level as the trailing wheel, which is the depth of the furrow, the land wheel D being, of course, kept up on the unploughed land to regulate this depth. The advantages of this plough are the simplicity of the several parts, and the diminution of friction in its action, thus allowing, except on very heavy or stony land, of the cutting of the two furrows being done with as much ease as with the ordinary plough making only one furrow. It requires very little attention on the part of the ploughman when once adjusted, the levers only requiring to be raised or depressed a little to suit any inequalities in the land, or when turning at the ends into a new set of furrows.

THE UNITED STATES' SIGNAL SERVICE.

DURING the late war two novel attempts were made to procure and convey military information in the field. One was the enterprise of a shrewd Yankee aeronaut, who undertook to spy out the secrets of the hostile camps along the Chickahominy by soaring over their heads and looking down upon them from the secure elevation of a balloon, which was attached to a cord and reeled in and out at pleasure. The idea secured for its author the rank and pay of a Colonel, but its results were not otherwise particularly brilliant. We "U. S. Army and Navy Journal" do not remember that anything of value was obtained of the enemy; while, on at least one occasion, they were near possessing themselves of the army balloon and an unlucky general officer, whose aerial steed had run away with him, and was in danger of carrying him, either into the enemy's camp, or on an involuntary trip to the mountains of the moon. Another novelty in these days was the Signal Corps, whose flags were seen flying from the tree tops, from the roofs of the buildings used as head-quarters, and from the summits of lofty towers which were extemporized in the woods along the picket lines of the army. Unlike the balloon enterprise, this signal service has stood the test of time, and, after rendering most important service during the war, has secured for itself a place in the permanent organizations of the army and navy. For the establishment of this corps we are indebted to the present Chief Signal Officer of the army, Brevet Brigadier-General A. J. Myer. General Myer is a gentleman of fortune and leisure, who, previous to the breaking out of the war, had devoted himself for years to perfecting a system of signalling. This system he early brought to the attention of the War Department. It was subjected to a thorough trial, which resulted in a favourable report; the system was eventually adopted, its author appointed Signal Officer of the Army of the United States, with the rank of major, and, in 1863, the Signal Corps was organized by an Act of Congress, and Major Myer appointed its chief, with the rank of colonel.

In spite of strong official opposition, Colonel Myer succeeded in maintaining his position and in establishing the Signal Corps on a firm foundation. He has also devoted much of his attention to perfecting his system of signalling. The result of his labours in this direction are before us in a manual of signals for the use of signal officers in the field and for military and naval students, military schools, &c., which has just made its appearance in a new and complete edition. This manual shows the perfection to which the business of transmitting intelligence by signals has finally been brought. Instead of a single code, we have here examples of ten different codes, all capable of easy application, and forming together a complete sign language sufficient for all possible needs of an army. Though a simple apparatus is employed, none is absolutely essential except such as can be readily extemporized. For official messages, a cipher is employed, and a cipher disc is furnished which is mechanical in its action and admits of innumerable changes, each made in a few seconds, and each forming a complete cipher. At the close of the rebellion, the chief signal officer at Richmond admitted that his best men had not been able to detect our cipher, while our officers claimed that they had seen no cipher which they could not read. As the movements of an army extend over sections of country where the usual signals cannot be used, or are not sufficiently rapid, a field telegraph train was organized early in the war, as an essential part of the Signal Corps' equipment. In addition to the instruments, the field trains carried, in ambulances or light waggons, rolls of insulated wire and light lance-poles on which the wire was elevated. This wire was wound on reels containing one or more miles, and could be run out rapidly by hand when the formation of the ground or other circumstances rendered the use of the waggon difficult or impossible. At Fredericksburg it is claimed that the field telegraph was first brought into operation on the field of actual battle, and worked under fire by the Signal Corps with gratifying success.

The flying telegraph was repeatedly and very extensively used on the marches and in the campaigns of the various armies of the United States, each army being furnished with one or more trains. Telegraphic lines were often erected by the corps with a rapidity which was remarkable. Though not nearly complete, and worked with many difficulties, these trains achieved a fair success, and were the models on which have been formed the flying telegraph trains now prepared for the army, and the use of which is taught at the Military Academy. Our signal officers also rendered important service to the navy during the war, and the formal thanks of the navy department were won at Fort Fisher. The plans of signalling are now taught to the midshipmen at Annapolis, and are given in the naval signal books for use throughout the service. In the signal manual, ingenious and simple modes of communicating between vessels, or between the shore and vessels, are given, in which lanterns, bells, rockets, guns, or flags are used. A special code, ingeniously arranged, for application to the message codes now in use, is also given, and the system of chronosemic signals, originated in the navy, fully explained.

A late regulation of the army provides for the issue of signal equipments and glasses to every military post in the United States, and a system of instruction to embrace the whole army, in the manner prescribed in the manual, is contemplated. This includes the application of the principles of signalling to the electric telegraph. The "General Service Code," given for the army and navy, can be used over the electric wires nearly as rapidly as the Morse system, and can be learned in a few days. Two foreign nations, Sweden and Denmark, have sent their representatives here, by permission of our Government, and made themselves acquainted with the practical workings of this signal system, for the purpose of adopting it in their several armies. France has adopted a field telegraph system, and teaches it at the camp of Chalons, and the time is not far distant when every military nation will avail itself of both semic and electric telegraphy.

PREPARING FIBRE FROM BAMBOO OR CANE.

AN improved method of preparing fibre from bamboo or cane for the manufacture of textile fabrics has been patented in England by M. Sautter, of 50, Rue de la Chaussée d'Antin, Paris. M. Sautter first removes the knots or joints and then splits the bamboo longitudinally into strips by means of sharp-edged instruments arranged for the purpose. After this, the lower and tougher portions of the bamboo are separated from the remainder, since the hard and tenacious fibre that grows nearer the ground requires a treatment which for the present purpose would be injurious to the upper and more tender parts. The bamboo is then boiled in caustic alkali of about 60deg. Beaumé, in an open boiler, until the siliceous and gummy matter is softened. This operation requires from six to ten hours, according to the age and quality of the bamboo. In this part of the process the time occupied will depend upon the character of the lignin, the tougher and more tenacious portions requiring the more vigorous treatment. The next stage in the process is to press the bamboo while hot, for the purpose of expelling the water, and so much of the siliceous and resinous matter as may be held in solution or combined with the bamboo; also to prepare it for the subsequent boiling and cleansing process.

The bamboo is then again boiled in a weak solution of caustic soda for about three hours, and afterwards for about two hours in soap and water, which cleanses and softens the fibre without reducing it to a pulpy condition or impairing its strength, which would be the result if longer boiled in caustic alkali. The bamboo is then washed in hot water until all the foreign substances are removed from the fibre, when it is prepared for carding by passing it through a machine hackle. It is next subjected to strong cards which reduce the fibre to a proper condition for spinning. It is necessary that the fibre be in a moist state during the operation of carding, but if water is employed for that purpose, the fibre is weakened and will be destroyed while passing through the cards; the fibre is, therefore, saturated with oleaginous vapours, which renders it pliable and lubricates it without impairing its strength. It can then be carded with facility, and a length of fibre retained of sufficient length and strength to be applicable to and valuable for textile manufactures and purposes.

It is well known that large quantities of what is commonly known as flock is used in the manufacture of woollen goods, and that the article is obtained from the cropping or shearing of cloth or woollen rags, which are first ground and reduced by a suitable machine to a short fibre. Now, it has been ascertained by repeated experiments that flock of superior quality can be prepared from the fibre of cane or bamboo, and at a trifling cost as compared with that produced from any previously known article. The cane or bamboo undergoes the same process as that above described in reference to the preparation of fibre for textile fabrics, and this additional application offers this advantage, that such part of the fibre obtained that does not answer fully the purpose for producing a good yarn may serve for the preparation of flock. In this case, such part of the fibres that has been put aside for making flock, or the whole of the fibres produced if flock only is to be prepared, is placed, after the boiling in caustic alkali has been completed, and, when ready for washing, into a rag engine provided with revolving knives, and so arranged that, while the cleansing process is being performed, the fibre is gradually brought into a suitable condition for the purpose specified. It is next dried and passed through a machine provided with pickers, which open and separate the fibre and prepare it for the principal operation of flocking.

ON THE USE OF SALT APPLIED TO AGRICULTURE.

AS the all-absorbing preoccupation of agriculturists is the discovery of manure, trade and industry have sought in every direction whence they could be obtained. It has been ascertained that the sea, which is known to contain so much wealth in its basin, is also an immense receptacle of manure. Sea wrack and other weeds are extensively employed in the agricultural improvements of many parts of the coasts of Brittany, Normandy, Provence, &c. Sea water has also been used for manure. The use of salt for agricultural purposes has especially attracted the attention of agriculturists, and, in consequence, of governments. The Paris papers, and notably the "Univers," have informed us ("Le Credit International") that the Financial Committee of the Council of State heard a few days ago the report of their chairman, M. de Laveney, on the abolition of the tax on salt used in food for cattle, and in the improvement of land. The Minister of Finance has earnestly accelerated the labours of the commission to which three years ago he entrusted the care of finding out the means of sophisticating in an effective manner the salt applied to agricultural purposes. This was the only objection of M. Magne to the amendments relating to the abolition or reduction of the salt tax. The essential point was to find the means of concilia ting the great interests of agriculture with those of the Treasury, to whom this tax yields an average annual income of from £750,000 to £875,000. Delegates from this commission have been sent to Germany, Russia, and other parts of Europe to study the application of salt to agricultural purposes. The problem appears to be nearest to its solution in Russia. The practical observations of agriculturists in Russia and in several farming districts of Prussia have served the commission of the Ministry of Finance as rules to help them in their experiments. They have obtained—not, however, without laborious study, and after a series of unceasing efforts—a result which will allow the realization of the innovation sought for simultaneously by farmers, by graziers, and by saline districts. The process of sophistication does not deprive salt of its tonic and vivifying properties, and fraud becomes therefore very difficult, if not impossible. It would entail so much trouble, so much expense, that none would venture to run the risk of prosecution for so small a profit. The inquiry of the Council of State will only have reference to the economical and administrative statutes. The enactment intended to remove the present *statu quo* will be the object of a special decree.

ARCHITECTURAL ENGINEERING.

THE following article upon the above subject, which we find in the "Scientific American," contains a fund of common sense well worth pondering upon. Our able contemporary observes that the sister arts of engineering and architecture are commonly considered as being distinct, and in one sense they are distinct; but there is a class of building which, while it gives scope to all skill in design which the finished architect possesses, also involves considerable knowledge of civil and mechanical engineering. We allude to the designing of buildings and works for manufacturing purposes. In many kinds of manufacturing, long established and systematized, there exists a regular method of building so far as interior arrangement is concerned, never modified except in unimportant details. The exteriors of such buildings vary greatly in the degree of beauty and appropriateness of their designs; but a large number are totally destitute of either, being simply stiff and ungraceful masses of masonry, which if not without form, are certainly destitute of comeliness. Others would be good designs were it not for their inappropriateness.

But it is not of exterior designs that we are about to speak. There is a field in which the highest success can only be reached by uniting the special requisites of skill in mechanical and civil engineering with the skill of the architect. In many industrial establishments strict adherence to one type of building is neither requisite or desirable. Circumstances connected with the location, the materials available for the erection of buildings, the character of the site, and other particulars not necessary to be enumerated, must, in some cases, and may, in any case, render more or less change necessary. As an illustration of this fact, we have in mind a case where a large industrial building, requiring very heavy walls to support the machinery, was erected on the side of a clay hill. The work was about two-thirds completed when it was found that the building and its foundations were gradually but surely sliding down hill. Of course, nothing was left but to tear down, and either begin over again upon a better foundation, or change the site of the building. Here was a grave error committed by an architect, of no mean reputation, simply by not taking into proper account the effect likely to be produced upon the clay basis by such a great weight as was necessary.

Our readers will doubtless recall some instances of terrible disasters arising from want of proper strength in manufacturing buildings, of which the fall of the Pemberton Mill, at Lawrence, Mass., was a most notable and lamentable example. We have, in our observations of different industrial works, often wondered that more such disasters did not befall, rather than so few. It is common to meet with errors in building arising from obvious ignorance of the practical working of machines, and their effects upon buildings in which they are placed, together with a total disregard of the effect likely to be produced by rhythmic movements and their attendant vibrations. We have seen power printing presses placed in positions, on top floors, where the ultimate destruction of a building, by their effects, would only be a work of time; and drop presses placed upon foundations so weak that they could not, by any possibility, be expected, by an expert, to remain *in situ* more than a week at the outside.

We believe that there is now, and has been for some time, a requirement for a special profession of architectural engineering. Because a man can build handsome churches, design a splendid front for a bank building, or erect an elegant villa, it does not follow that he is competent to build or superintend the building of a grist mill, or even a saw mill. To properly design and complete works of the latter character requires a knowledge of the machinery to be used, the nature of the work they are designed to perform, the points of the structure likely to be subjected to strain, and knowledge of the resources whereby such points may be adequately strengthened. We are aware that there are some architects who have devoted themselves to this speciality, and have acquired skill in it, but they are too few to meet the requirements of the public, and, consequently, much of the work, which only such experts can properly perform, goes into the hands of men who, however skilful in other departments, are certainly incompetent to win enviable fame in this.

Legal Intelligence.

THE EDMUNDS CASE.

THE Court of Arbitration, consisting of Mr. Manisty, Q.C., umpire; the Hon. G. Denman, Q.C., and Mr. C. Pollock, Q.C., arbitrators, appointed to inquire into all matters in dispute between Mr. Edmunds and the Crown, met at the Court of Common Pleas, Westminster Hall. Mr. Digby Seymour, Q.C., Mr. Napier Higgins, and Mr. Haviland Burke, appeared for Mr. Edmunds; and the Attorney-General, Mr. Field, Q.C., and Mr. Archibald for the Crown.

Mr. Denman briefly explained that he and Mr. Pollock, acting under an order of the Court of Common Pleas, had chosen Mr. Manisty as umpire in this case, and they had agreed to act as arbitrators in this case, and that they had thought it desirable they should sit together. They had no feeling in the matter either for the one side or the other, and sat therefore as unbiassed arbitrators between Mr. Edwards and the Crown. He (Mr. Denman) knew nothing whatever of the case beyond what had been publicly rumoured. It would, no doubt, occupy some considerable time in investigating, and, looking at its importance, he thought it very desirable that the Court should sit *de die in diem*. He and Mr. Pollock had consulted together upon this question, and they had come to the conclusion that, if agreeable to all parties, Thursday, October 21, would be a suitable day for opening the case, and then to go on *de die in diem*.

The Attorney-General quite agreed to the course proposed. He would, however, venture to suggest that, as the Crown would have to establish the case, the accounts of Mr. Edmunds should first of all be investigated.

After some discussion, it was agreed that the Court should meet again on Thursday, October 21, in the Court of Common Pleas, Westminster.

Correspondence.

THE INFERIORITY OF OUR COFFEE.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—My attention has been drawn to an article in a leading daily paper expatiating on the great nferiority of coffee used by us as a beverage, cwhen compared with its excellence in some other ountries, and the writer fortifies his remarks by bserving that "a cup of good coffee is as rare, in England, as a blue diamond." Without going into the entire analysis, untold adulterations and general treatment of coffee in these islands—which might be too long for insertion—a few remarks on its proper and improper torrefaction must not be regarded as offering any extenuation of, or in any degree accounting for, the very inferior article supplied us in the ground state under the name of coffee, but to inform those who may be desirous of preparing their own; and to induce scientific men to direct their attention to this most important subject.

That, to all that have visited the Continent, a cup of good coffee is as rare in England as a blue diamond is an incontrovertible fact, for, although the finest coffee the world produces is brought here, we English, if even we procure the choicest quality and grind our own, have but a vague conception of what a cup of good coffee really is; hence, it is evident, some "radical defect" must, as has been stated, underlie our mode of preparing the berry. Considering the vast importance of this article, socially and commercially, and the great strides science has recently made, it appears incredible the cause of this defect has never been thoroughly investigated, and an improvement in its preparation suggested by one or other of our great analytical chemists. At the first blush, it would appear to be a grave reflection on our wives, cooks, and housekeepers, but a very little scientific elucidation will dispel any such idea.

The coffee berry is roasted in this country not only in comparatively close iron cylinders, but also in large quantities at a time, by which means the grosser elements, instead of being evolved and evaporated, become condensed; and from the chemical action of the chlorogenate of potassa upon the cellulose or woody fibre, the generation of a new and most acrid bitter substance, called tannin, is formed (never to be found in its natural state) which completely deprives coffee of its true flavour. The method adopted by the natives of Ceylon, who only take the quantity of berries required for present use, and roast them in an earthern pot, though simple, is the only compatible and philosophical process; for by preparing coffee in small quantities, in open vessels, all the mineral and azotized substances are freely evaporated, and the formation of tannin entirely prevented, whereby the caffeine is retained in its pristine purity.

Now, caffeine being to coffee what theine is to tea—the primary principle—its complete preservation should be our chief aim; consequently, the infinite superiority resulting from this primitive mode of treating the berry in Ceylon and other oriental countries where labour is cheap, at once explains our radical defect, and reveals the true secret of its more exhilirating properties and full aromatic flavour. From the foregoing deductions, it is but too manifest that until the hand of science devise some means of preparing the berry in perfect accordance with its constituents, and in quantities commensurate to the requirements of a commercial community, coffee as it ought to be, must ever remain with the multitude, "as rare as a blue diamond!"—I am, Sir, yours, &c.,

London, July 6. G. MARK.

THE CHANNEL TUNNEL.

SIR,—Referring to the application recently made by a deputation of the promoters of the Channel Tunnel, who waited upon Mr. Bright to request a Government guarantee on £2,000,000 sterling, for the purpose of making experiments to test the practicability of boring a submarine tunnel under the Straits of Dover, and noticed in your last issue, I beg to draw your attention to a statement which appeared in the "Moniteur" of the 30th ult., a translation of which I enclose, containing some facts, in connexion with that undertaking, which I think may be of interest to your readers.—I am, Sir, yours, &c.,

HENRY STEAD, Sec.

18, Old Broad-street, E.C., July 7.

[TRANSLATION.]

Several English papers have announced that Mr. Bright, the English President of the Board of Trade, has received a deputation of the promoters of a proposed submarine tunnel under the Pas de Calais (Straits of Dover), who stated to him that the official commission of engineers appointed by the French Government had reported favourably on the scheme, in consequence of which the promoters ask the two Governments to guarantee them 2½ per cent. upon the 50,000,000f. (£2,000,000 sterling), which the preliminary experiments connected with this project are expected to cost. The commission declared, in effect, that the construction of a tunnel would not be impossible, without offering any opinion as to the outlay of time and money involved, and supposing there were no percolation of water. The promoters have made use of this declaration to ask for a guarantee of interest; but, in its later meetings, the commission completely rejected this demand, and it is difficult to imagine that the Government would be disposed to authorize an outlay of 50,000,000f., which would be 25,000,000 (£1,000,000 sterling) for France, to make experiments on this project, which, even if it could be carried out, would be open to great objections. This scheme, besides, is no other than that of M. Thomé de Gamond, which was rejected twelve years ago because the commission declared, before offering an opinion, that it would be necessary to expend 500,000f. (£20,000), in preliminary experiments. It is clear, then, that an outlay a hundred times larger, for the same purpose, would not be authorized unless success were absolutely secured.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Meeting for the Week.

WED.—Aeronautical Society of Great Britain.—Reading and Discussion of Papers, at 8 p.m.

Naval, Military, and Gunnery Items.

THE field telegraph waggons have arrived at Aldershot from Chatham, and will henceforth be worked in concert with the troops, under the direction of Captain Stodhart, Royal Engineers.

THE Viceroy of Egypt is said to have the intention of creating a foreign legion to be recruited in Europe, but principally in France. This corps will be in garrison at Suez and Ismail, and its special mission will be to guard the canal and the isthmus.

A TEN-INCH columbiad gun has been placed on the spot where Generals Grant and Pemberton arranged the terms for the surrender of Vicksburg, an inscription denoting the fact being engraved upon it. The marble monument which was originally erected there had been hacked and marred by vandal relic seekers.

WE understand that the Admiralty have determined upon continuing the command of the "Island of Ascension" and Her Majesty's ship "Flora" under the pennant of a commander, and not of a captain, as heretofore. Under these altered conditions, Captain Arthur Wilmhurst will retire for the present upon half-pay, and the appointment given to an officer of the junior rank.

Colour Serjeant Montgomery, of the 30th Middlesex (Ealing), was trying a new breech-loading small-bore on Wednesday week, and incautiously placed his hand over the muzzle of the rifle, when a discharge unexpectedly took place, and the contents passed through his hand, damaging it fearfully. He was the winner of the £100 Wimbledon Cup last year, but it is feared may not again be able to use his rifle.

The soldiers' monument at Westborough, Mass., was dedicated June 17. The monument is a granite shaft 28ft. high, hand somely sculptured, and bearing on its sides the names of the soldiers of the town who fell during the war; also the motto—"Pro Patria mortui sunt." The soldiers' monument to be erected at Plymouth, Mass., will be placed in position at an early day, and will be dedicated about August 1.

The "Donegal," screw line-of-battle ship, which has been serving as coastguard and reserve ship at Rockferry, Birkenhead, was put out of commission yesterday week at Portsmouth, and her officers and crew turned over to the "Resistance," 4½-inch plated iron frigate, 3,700 tons, 600-horse power, 18 guns, and another ironclad—albeit a thin-skinned one—was thus added to the number of vessels forming the Coastguard and Reserve Fleet on duty in home ports.

The Board of Trade has awarded a gold watch and chain to Captain Stefano Trifliette, of the Italian barque "Anita Tagliavia," for his humane services to the crew and passengers, 98 souls in all, of the British ship "Omar Pasha," whom he received on board his vessel on the occasion of their own vessel being burnt at sea on the 22nd of April last. They have also awarded a gold watch and chain to Captain R. Niemeyer, of the "Hamburgh barque Pyrmont," in recognition of his humane services to the passengers and members of the crew (31 in all) of the late ship "Blue Jacket," of Liverpool, whom he picked up at sea on March 16, 1869, on the occasion of their vessel being burnt in lat. 50 26 S, long. 47 W.

The following telegram respecting the Bermuda Dock was received at the Admiralty on Wednesday afternoon from the commander of her Majesty's ship "Helicon," at Lisbon:—"Helicon" arrived at Lisbon, July 6, at 6 p.m., and sails for Devonport with dispatches at 8 p.m. Captain Boys, of her Majesty's ship "Warrior," off the island of Porto Santo, July 4, sends the following communication:—Bermuda dock arrived at Porto Santo at 2 p.m. on 4th inst. Light breezes and calm all the passage. Proceeded this evening (4th) on voyage to Bermuda. No difficulty whatever experienced.

The successful candidates who passed the examination for commissions in the Royal Marines in November last were informed on January 15 that their names were placed on a list in the order in which they passed, and that commissions would be offered to them, provided they have not attained the age of 20 when the vacancies for commissions occur. Every week officers are placed either on the full-pay or half-pay list, but no communication has been made to the disappointed candidates, who feel that faith has been broken with them after fulfilling the required conditions and passing a very severe examination.

Admiral of the Fleet, Sir William Bowles K.C.B., died last week. The deceased officer entered the navy very shortly after Nelson, whose career terminated nearly 65 years ago. Sir William was not fortunate enough to have figured prominently in any great naval engagement, but it is generally admitted that he possessed great administrative talents. He was promoted to the rank of captain in 1807, and held office under successive Boards of Admiralty at Whitehall, and at the Custom House as Controller of the Coastguard. He was also repeatedly employed afloat. His last appointment was as Commander-in-Chief at Portsmouth. Sir William Bowles was an ardent supporter of the Royal Naval School at New Cross, and only a few weeks since attended a meeting of the corporation and made an interesting speech on the various points at issue.

Miscellanea.

At a general assembly of the members of the Royal Academy, held on the 30th ult., at Trafalgar-square, Mr. E. M. Barry was elected a Royal Academician.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending July 3, was 4,948. Total number since the opening of the Museum, free daily (May 12, 1858), 1,597,782.

Three sheep were found buried in a snow drift last week in one of the recesses of the mountain High Street, in Westmorland. They were recovered alive. Snow was still lying in some of the shaded parts of Skiddaw last week.

A dispatch from Nimes reports an explosion by firedamp on Tuesday week, at the coal mines of Bessegos, by which eight persons were killed and thirteen others dangerously injured.

Some Californian gold bars which recently arrived at Southampton by the steamers "Donau" and "Bremen," came to New York by the Pacific Railroad. They were delivered in London within 20 days from the time of their dispatch from San Francisco.

The number of Cornish pumping engines reported for May is 18. They have consumed 1,377 tons of coal, and lifted 10·2 million tons of water 10 fathoms high. The average duty of the whole is, therefore, 50,100,000lb., lifted 1ft. high, by the consumption of 112lb. of coal,

The most rapid redistribution of races ever witnessed seems likely to occur during the present generation in the influx of Eastern people to the Western States of America on the Pacific. During the year 1866 the arrivals in California from China and Japan were 2,300, in 1867 they were 3,300, and in 1868 they were more than 10,000, while this year they are expected to exceed any previous total.

The little English sparrows, which have been introduced in the vicinity this season, have already done a marvellous work of cleansing, says the "New York Times." In the upper parts of the city, in Jersey City, in Hoboken, and especially in Brooklyn, which hitherto has been the very paradise and elysian fields of worms, the pest of former years is hardly noticeable.

A quantity of native tobacco, grown in Metcalfe, has been brought into Jamaica in an unmanufactured state. It has been pronounced by good judges worth 1s. per lb., though inferior to some specimens of native growth already brought to this market. This tobacco growing and curing business is worthy of encouragement, for we see no reason why, under proper management, Jamaica cannot be made to produce as good an article of tobacco as any obtained from Cuba.

An unfounded report has been in circulation to the effect that the British residents in Paris had subscribed £6,000 in aid of the ex-Railway King. The object his friends have in view is to realize a fund of £4,000, which will purchase for him an annuity of £500 per annum for life. The necessary amount has not yet been obtained, but it is to be hoped that many additional contributions will be placed on the list.

A special committee has been formed at Amsterdam for the reception of workmen coming to visit the Exhibition of Domestic Economy in that city. Lodgings have been provided at the rate of 60 Dutch cents for bedrooms of a better kind, and 40 for the second, for the special benefit of Belgian artizans and workmen provided with certificates of good character, signed and delivered by the Brussels committee.

In Great Britain the quantity of coal-dust remaining unemployed is calculated at 28,000,000 tons. Various methods have been attempted to convert it into useful fuel by compressing it into cakes, but the operation is not sufficiently remunerative. In Belgium they follow another plan, which seems to answer better. They mix coal-dust with 8 per cent. of tar, and then press it into cakes, which are found to make excellent fuel for steam engines.

Three new streets are ordered to be pierced in that quarter of Paris known as Les Ternes, beyond the Arc de Triomphe at the end of the Champs Elysees; these streets are to be named after Lebon, Torricelli, and Faraday. There are already several streets in Paris bearing the names of distinguished foreigners, and the fact deserves to be recorded as an instance of international recognition and courtesy worthy of imitation.

A pleasant relief to the dull appearance of the river frontage of the New Palace of Westminster has just been effected by placing 50 large hansome boxes of evergreens on the terrace. These evergreens have been brought from the Royal gardens at Kew, and have been placed where they now stand under the direction of Mr. Smith, the head gardener. If this experiment is successful, next spring a considerable addition will be made.

Lloyd's agent at Buenos Ayres reports the following accident on May 24 at the fete given in commemoration of the anniversary of the declaration of freedom:—An aeronaut, named M. Baraille made an ascent in a balloon from the centre of the Plazza. It remained stationary over the city for some time, there being no wind, and on descending fell into the harbour. A number of boats and a small steamer named the "Cavour" put off to the rescue of the aeronaut, who was drowning in his car. By some misfortune the balloon in rolling about came in contact with the funnel of the steamer, and, the gas getting ignited, exploded with terrible force, blowing the crew overboard, as also those in the boats. The steamer was set on fire, and sustained much damage. The Buenos Ayres papers state that eight persons were fatally injured and 25 were much burnt and injured.

The following is a return of the quantity of coal exported from Grimsby, in June, 1869:—To Belgium, 762 tons; Denmark, 4,090; Egypt, 1,494; France, 5,513; Hanseatic Towns, 899; Holland, 499; Norway, 223; Prussia, 839; Russia, 8,488; Sweden, 978; Spain, 241; and Turkey, 253; total, 24,284 tons; coastwise, 2,246 tons—26,530 tons; corresponding period of 1868, 24,802 tons; ditto, coastwise, 3,102 tons—27,904 tons, decrease, 1,374 tons.

At a meeting of the Royal Horticultural Society, held on Tuesday, Mr. W. Wilson Saunders, F.R.S., in the chair, the following candidates were elected Fellows of the Society, viz., Captain Cotton, Messrs. Samuel Dobson, Thomas Hoblyn, and Edward Horne, Dowager Countess of Shannon, Major-General Henry Blois Turner, &c. This was by far the most interesting meeting of the season, the Council-room abounding in rich and beautiful flowers.

The number of visitors to the South Kensington Museum during the week ending July 3, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 21,906; Meyrick and other galleries, 7,489; on Wednesday, Thursday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 6,608; Meyrick and other galleries, 243; total, 36,246. Average of corresponding week in former years, 12,030. Total from opening of Museum, 8,596,076.

M. Fontana, architect to the Czar's Ministry of the Household, is charged to construct, on the model of the London Crystal Palace, the building for the exhibition which is to take place at St. Petersburgh next year. A sum of £27,000 is allowed for this structure; the number of workmen employed is at present 400, but will be speedily augmented, for the building must be completed externally by September 1 next, and entirely by May 1, 1870.

The dross accumulated in iron works, to the amount of millions of tons, is known to contain from 25 to 50 per cent. of iron, but the difficulty of extracting is very great, the metal being intimately combined with various silicates and other substances which are not easily separated by fusion. Lime, indeed, will decompose these silicates, but the iron thus obtained is brittle. Nevertheless, M. Fleury has recently made a successful attempt to obviate this drawback by slaking the lime used for the purpose in water containing a certain proportion of some alkaline chloride.

Some years ago, the Emperor of the French was astonished at the great space occupied by flour when packed in sacks in the usual manner, and imagined that it might be compressed into a much smaller bulk, and be thus rendered of easier transport. He at once authorized some experiments to be made on the subject, which resulted in the flour being submitted to powerful hydraulic pressure, and served to the various regiments in tin cases, not only occupying a very small bulk, but protecting the flour from the damp of the atmosphere, and so preventing it from becoming mouldy.

Dr. Carriere, of St. Jean du Gard, in reply to the offer of the Marquis d'Orches, of a premium of 20,000 francs, for a practical method of determining death, furnished the following, which he says he has practised for forty years:—Place the hand with the fingers closely pressed one against the other, close to a lighted lamp or candle; if alive, the tissues will be observed to be of a transparent, of a rosy hue, and the capillary circulation of life in full play; if, on the contrary, the hand of a dead person be placed in the same relation to light, none of the phenomena are observed—we see but a hand as of marble, without circulation, without life.

The produce of the numerous slate quarries of North Wales is estimated at the present time to be not far from 350,000 tons annually, representing in money value about £865,000, or an average of early £2 10s. per ton. The produce is made up, as follows:—Festiniog and surrounding veins, 98,000 tons; Penrhyn and surrounding veins, 109,000 tons; Llanberis veins 75,000 tons; Nantille veins, 40,000 tons; Corris veins 20,000 tons; making a total of 342.000 tons. The number of hands employed, including shippers, men on new works, and all about the quarries or dependent on quarrying, is estimated at 9,400. Of this total the Festiniog veins employ 2,900, Penrhyn 2,500, Llanberis 2,000, Nantille 1,300, and Corris 700.

Last Thursday evening the Society of Arts gave a conversazione at the Kensington Museum. The grounds presented a picturesque appearance, being illuminated with variegated lanterns, and lamps were tastefully disposed in the flower beds. Between four and five thousand responded to the invitation, and some time before the opening of the galleries a long line of carriages were waiting to set down their occupants. Refreshments were served in several rooms during the evening. The band of the Grenadier Guards, under the direction of Mr. Dan Godfrey, and the band of the Chatham Division of Royal Marines, under Mr. Kappey's conductorship, were in attendance, and performed a choice selection of music in the interior and exterior of the building.

A NOBLE addition has been made to the entrance hall of the British Museum, in the shape of a vase of great beauty and fine proportions, which was discovered in the course of excavations made just 100 years ago, in the villa of Hadrian, at Palestrina. It about 10ft. in height, including its base, and probably dates from the early part of the second century of our era. The vase in the last century appears to have belonged to a certain Mr. John Boyd, probably a Scotchman, though resident in England; but it was purchased only a few years since by the trustees of the Museum from a gentleman named Hugh Johnson, and until recently, it was lying, in a sadly mutilated state, among the Halicarnassian and other marbles, under the unsightly sheds which still disfigure the façade of the Museum. It has been carefully restored under the superintendence of the Keeper of the Greek and Roman Antiquities, the broken parts being rejoined with copper fastenings.

THE annual conversazione of the Royal Institute of British Architects, held on Thursday evening week, was numerously attended by members of the architectural profession, and by artists and scientific men. The rooms of the society in Conduit-street were expressly decorated for the occasion, and filled with choice works of art (many of which were lent by the President, Mr. W. Tite, M.P.), including some beautiful specimens of majolica, Salviati's mural mosaics, Venetian glass, and other specimens of art manufacture lately reintroduced in this country. Among the paintings on the walls were some by Messrs. E. W. Cooke, R.A., S. Hodges, Marks, Holiday, Donaldson, the late C. Stanfield, and David Roberts. An interesting collection of original sketches by E. Goodall and H. W. Brewer, and two busts (one of the Earl of Derby, and the other of the President of the Institute), by Mr. Theed, attracted much attention. The band of the Coldstream Guards attended and performed during the evening under the direction of Mr. F. Godfrey.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3832
BUILDINGS AND BUILDING MATERIALS—3833, 3839, 3845
CHEMISTRY AND PHOTOGRAPHY—3843
CULTIVATION OF THE SOIL, including agricultural implements and machines.—3830
ELECTRICAL APPARATUS—None.
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3803, 3808, 3813, 3820, 3834, 3855, 3861, 3864, 3866
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3846, 3852
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—3802, 3805, 3809, 3810, 3814, 3821, 3837, 3838, 3840, 3854, 3858
GENERAL MACHINERY—3801, 3804, 3806, 3817, 3824, 3836, 3844, 3847, 3853, 3869
LIGHTING, HEATING, AND VENTILATING—3812, 3818, 3826, 3829, 3843, 3865, 3868
METALS, including apparatus for their manufacture—3822, 3828, 3842
MISCELLANEOUS—3807, 3811, 3816, 3819, 3826, 3827, 3831, 3833, 3835, 3849, 3850, 3867, 3870
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3813, 3825, 3841, 3863
SHIPS AND BOATS, including their fittings—3851, 3856
STEAM ENGINES—3815, 3848, 3857
WARFARE—3859

3801 A. WATT, Gracechurch-street. *Rollers.* Dated December 15, 1868.

The inventor constructs the rollers, cylinders, or metallic surfaces of zinc, type metal, or any suitable compound of mixed metals, turning or facing them to a smooth surface in a lathe or other suitable machine. The surfaces, whether cylindrical or otherwise, thus smoothed are thoroughly cleansed by immersion in a bath, formed, by preference, of a solution of cyanide of potassium, and afterwards completely coated with copper by immersion in a bath formed by a solution of cyanide of potassium mixed with a solution of cyanide of copper, or cyanide of potassium, mixed with a solution of nitrate of copper, or cyanide of potassium mixed with a solution of sulphate of copper. He then subjects them to the process known as electro-coppering by the battery until a coating of copper of sufficient thickness to allow for the said surfaces to be turned, filed, or polished to a smooth and even face.—Patent abandoned.

3802 J. H. BROWN, Romsey. *Helmets, hats, &c.* Dated December 15, 1868.

The inventor uses the cuttings, fleshings, and shavings obtained during the manufacture of leather from the skins of the calf, sheep, buck, doe, goat, and kid. These cuttings, fleshings, and shavings having been first thoroughly picked over to free them from dirt and other impurities, and from any pieces of what is termed the grain side of the skin, are well washed in a weak solution of soda or other suitable lixivium, and having been mixed together in proportions which are regulated as required, and with reference to the desired application, are next reduced to a filamentous fibrous pulp by suitable machinery (that used for the production of paper pulp being preferred), warm or cold water, according to the temperature of the weather, being used therewith. When the pulp has been reduced to about the consistency of that used in the manufacture of strong writing paper, it is passed through a machine called a "knotter," or through a sieve or other suitable contrivance, to free it from all knots and unreduced particles. During the latter process, to every 100lb. of the materials above mentioned, 1½lb. of sulphuric acid, diluted in two gallons of water, is added, and, when well incorporated, 5lb. of dry animal size reduced to a fluid in two gallons of warm water, and 5lb. of alum dissolved in two gallons of water are added. When these ingredients are well mingled with the pulp, the whole mass is then in a fit condition for the production of the required articles. —Patent abandoned.

3803 C. MATHER, Salford. *Cleaning cotton.* (A communication). Dated December 15, 1868.

This consists in the application of a stationary plate or bar between the ordinary fine-toothed cylinder and the revolving fluted guard. The edge of this plate or bar is sharp, or nearly sharp, and the seeds or other impurities are held against the stationary plate or bar, while the revolving fluted guard strikes them off the fine-toothed cylinder. When the seeds or other impurities are free from fibres they drop out of the machine, and the fibres are removed from the fine-toothed cylinder by a revolving brush in the usual manner.—Patent abandoned.

3804 H. A. BONNEVILLE, Sackville-street. *Motive power.* (A communication). Dated December 15, 1868.

This consists, first, in the suppression of the ordinary distributing valves of apparatus for obtaining motive power, and in replacing them by pistons. Second, in a mode of distributing and heating the air. Third, in the introduction of and mode of introducing air by the upper part of the furnace. Fourth, in a manner of mending with fuel the furnace. Fifth, in a combination of parts which allows of the said apparatus being regulated automatically, and of increasing or diminishing at will the combustion in order to obtain this regulation. Sixth, in a peculiar arrangement of the furnace.—Patent completed.

3805 H. WILLIAMSON, Denton. *Hats.* Dated December 15, 1868.

This consists in dispensing with stitching the silk, cotton, or other lining together before placing it in the crown of hats, and forming the lining of such hats with any suitable fabric by coating one surface of such fabric with any substance which would become soft and adhesive, and yet not be injured by means of heat applied to it, so that such fabric map be cut into pieces to suit the shape of the crown, and be caused to adhere to the inside of the crown by means of heat and pressure applied by the ordinary india-rubber bag used in the hydraulic machine for pressing hats, thus lining such hats to the exact shape of the crown without any stitching being required.—Patent completed.

3806 G. BAUMANN, Wurtemburg. *Valves.* Dated December 15, 1868.

This consists in the addition of another slide valve to the two slide valves now generally in use. The valve of the engine is actuated by connecting it to a special piston working in a special cylinder. The admission of pressure to and the exhaust of the latter is governed by the combined effects of a second and third slide valve, the second slide valve being the piston itself, and the third slide valve being actuated by a special piston working in a special cylinder having pressure and exhaust in common with the cylinder of the engine through ordinary steam ways.—Patent completed.

3807 R. S. GARDEN, Piccadilly. *Cartridge pouch.* Dated December 15, 1868.

This consists in adapting and fitting loosely in the interior of a cartridge pouch or box two rows of cells or receptacles for the cartridges, capable of being readily moved in and out of the pouch or box, and made of metal or other suitable material, one row being over the other, and is so attached to the other at each end by a connecting piece or pieces of metal or other suitable material, that when the cartridges in the top row have been used the lower row of cells or receptacles filled with cartridges can be readily moved up into its place.—Patent abandoned.

3808 W. BYWATER, Holbeck. *Manufacture of felt.* Dated December 15, 1868.

This consists in the application of two instead of one eccentric shaft, as heretofore used, both shafts working uniformly together, so as to produce like endway motions to these rollers, by which a more uniform or even felting will be obtained with less wear and tear to the machinery employed. It relates, second, to a method of syphoning out the water of condensation from the steam heated rollers in such hardening machines. For this purpose, the inventor introduces at one end of the copper, steam heated rollers a hollow tube open on one side, into which opening he inserts a thin plate of copper the length of the tube, for the purpose of dividing it into two channels, so as to operate whichever way the roller revolves; the plate being fastened to the inside of the periphery of the steam heated roller, conducts out the water therefrom through a tube in the axle of such roller so soon as motion is given thereto.—Patent completed.

3809 J. W. CHILCOT, Portsea. *Stays.* Dated December 15 1868.

This consists in the employment of metal eyelets inserted in the seams or bones, or in both, whereby the seams and bones are materially strengthened, and the stitches are prevented from breaking away.—Patent abandoned.

3810 C. A. B. POCOCK, Durham. *Bedsteads.* Dated December 15, 1868.

The frame of the bedstead is formed of tubes, by which means great strength is obtained together with lightness. Across the frame is stretched a piece of canvas, or like material, which is laced to the sides of the frame, the lacings being passed around the tubes, and by reason of the tubes being round, or it may be oval, in section, the lacings will not chafe or cut through. To the side tubes of the tubular frame suitable legs are attached by means of bolts or rivets, upon which the legs can turn, so that when the bedstead is out of use the legs may be turned down to lie in the same plane as the oblong tubular frame. The legs are made to fold up inside the frame and towards the ends; when the bedstead is required for use the legs are turned out from the frame. When they have been turned through somewhat more than a quarter circle, a pin or stop projecting out from each leg comes against the under side of the tubes which forms the sides of the frame, and the legs are thus stopped from turning further. A head rail may be similarly jointed to one end of the frame, so that it may either be caused to lie in a plane parallel with the frame, or to stand up from it nearly at right angles, it being for this purpose turned round through somewhat more than a quarter circle.—Patent abandoned.

3811 C. E. BROOMAN, Fleet-street. *Diving.* (A communication). Dated December 15, 1868.

The chief object of this invention is to enable persons engaged under water in any form of subaqueous machine or apparatus, to hold conversation with persons above water. The inventor places a plate or partition of metal or other material across or at either end of a speaking tube, one end of which communicates with the person above water, and the other end with the person below water, or the plate or partition may be a fixture to the subaqueous machine or apparatus, or form part of it, or be fixed to or form part of an apparatus above water. The object of such plate or partition is to prevent the compressed air in the subaqueous machine from escaping, and at the same time allow the sound to pass with only a slight diminution in its force.—Patent completed.

3812 M. LOCKHART, Douglas. *Ventilating.* Dated December 15, 1868.

This consists in leading a pipe down the chimney; this pipe is turned up at its lower end, where it terminates in a box or series of tubes, or holes are formed in a corrugated plate or otherwise, each box, tubes, or plate, being situated above the stove, or elsewhere, at the chimney bottom. The top of the pipe extends a little above the chimney, and carries a horizontal cup fitted with a vane which always keeps the open end of the cup to the wind. A portion of the pipe is free to revolve with the cup, and carries a guard, the back of which is always kept to the wind. The invention also applies to mine shafts, tunnels, &c.—Patent completed.

3813 M. BROWN-WESTHEAD and R. SMITH, Manchester. *Bobbins.* Dated December 15, 1868.

Upon one end of the bobbin or spool is a disc of cardboard or thick paper, through which a pin passes, and is driven into the filled-up centre of the bobbin or spool, it being made up solid for that purpose, but the pin is not sufficiently driven in for the head to bind upon the disc, so as to prevent it from turning. The end of the thread or twine is passed through a perforation in the disc; when therefore, a length is drawn off for use, the disc is caused to revolve, but as it requires some degree of force to cause that motion, it acts as a drag, and tends to prevent the thread or twine from unwinding beyond the required length. In a modification of the previous arrangement, a portion only of the disc is used and formed of metal. It is confined to the bobbin by the pin, as before described, and is in like manner provided with a perforation through which the end of the thread or twine passes.—Patent completed.

3814 J. FRAZER and W. NAAR, Bayswater. *Mattresses.* Dated December 15, 1868.

The chief object of this invention is to provide for the adjustment of the upper surface of spring matresses, so as to set the head of the mattresses higher than the foot. For this purpose the mattress is made with a base and an upper frame, which are connected together by the springs; and applied to the ends of the frames are fastenings (straps and buckles or their equivalent) for drawing the frames together, so that the foot of the mattress may be depressed and the head elevated at pressure.—Patent completed.

3815 P. KOTZO, Pesth. *Steam engines.* Dated December 15, 1868.

The chief object of this invention is to construct a condenser for steam engines which will work efficiently without the aid of an air pump. The condenser consists of a case rectangular in plan at its upper part, but partially extended laterally at its base to form a broad and steady bearing for the steam engine cylinder. This cylinder is cast with or has fitted to it a rectangular extension, which fits the top of the condenser. This casting is formed at its opposite ends with valve chambers, which connect respectively with the ends of the cylinder and with the outer compartments of the condenser. These compartments open into a central compartment, but are closed by means of valves. Leading from the bottom of the central compartment is a water discharge pipe, and at top it is closed by a cover, which has cast in it a steam exit pipe. There are valves for admitting the exhaust steam from the opposite ends of the cylinder into the condenser, and pierced pipes for discharging cold water in the form of spray into the steam to be condensed.—Patent completed.

3816 T. WILSON, Birmingham. *Signalling.* Dated December 15, 1868.

It is best to describe this invention in connection with railway carriages. On each end of the carriage the inventor fixes a metallic or other air chest or chamber, into which chambers the ends respectively of the signalling tube running along the carriage open the ends of the tubes opening into the backs of the chambers. In the front of the chamber are two openings; one of the openings is closed by a spring valve, and to the other opening a flexible coupling tube is attached of sufficient length to extend from carriage to carriage. To the free end of this tube a metallic or other tubular coupling plug is fixed, the plug containing a spring valve. The spindle of the valve is situated in the axis of the tubular coupling plug, and projects a short distance from its end. When the projecting valve spindle is not pressed upon, the valve in the tubular coupling plug is closed by its spring.—Patent abandoned.

3817 J. T. GRICE, Birmingham. *Tubes.* Dated December 15, 1868.

This consists in making the sides of the rolls of a zigzag or other figure, which will accord with the pattern or design to be formed on the tube or rod. For example, if the pattern or design consists of or contains a series of lozenge-shaped divisions, the inventor makes the sides of the rolls of a zigzag figure, corresponding to one side of the series of the lozenge-shaped divisions, and by the operation of the rolls the line produced at the junctions of the rolls follows the lozenge-shaped pattern or design instead of forming a straight line. He varies the shape of the sides of the rolls to suit the particular pattern to

be produced. The ornamental rolls made according to this invention gear into one another at their peripheries, the projecting part of the side of one roll engaging with the depressed part of the side of the adjacent roll.—Patent completed.

3818 J. E. SCRIVEN, Mulhuddart. *Heating.* Dated December 15, 1868.

This relates to that class of apparatus in which the furnace or firebox is composed of a series of iron rings or short vertical casings placed one above another. The inventor forms the base plate with a ledge around it, so that its central portion rises somewhat within the lower ring or vertical casing, the bottom of which rests upon the aforesaid ledge of the base plate. This lower ring or casing, which is provided with an adjustable door or doors, constitutes the sides of the ashpit, and is formed at its upper edge with a broad rim or shelf, having a small vertical ledge running around its outer edge. This rim or shelf receives and supports the firebars, as also a second ring or vertical casing whose lower edge rests upon the broad rim or shelf of the ashpit casing in the space between the firebars and the small vertical outer ledge. This ring or vertical casing is formed with a small hopper-shaped opening, through which a stoking iron may be passed by clearing away the clinker and other stoking purposes; it is furnished with a door, the position of which is adjustable by a rack or other suitable means, so as to regulate the quantity of air admitted in an uniform manner.—Patent abandoned.

3819 J. MILL, Southampton. *Heating press plates.* Dated December 16, 1868.

This consists in employing in connection with the said screw press an apparatus of rectangular form, composed of perforated tubes or passages, supplied with gas through the medium of a flexible pipe or otherwise, of corresponding suitable dimensions to the plates to be made hot, which are also enclosed within a rim or outer case for the purpose of concentrating or confining the heat from the lighted jets of gas more effectually to the plates placed horizontally in sets immediately above the same, so as to admit of the apparatus being readily removed on the plates being sufficiently heated for the operation of pressing to be formed in the usual manner.—Patent abandoned.

3820 W. COTTON, Loughborough, and E. ATTENBOROUGH, Nottingham. *Fabrics.* Dated December 16, 1868.

The improvements relate to that class of machinery for the manufacture of looped fabrics in which the needles point in a vertical direction, or nearly so, from their leads upwards, and the work produced passes away at or near a horizontal direction. The needle bar is actuated by suitable cam movements, to give the needles a movement to and fro of the presser, as well as vertically for knocking off, whilst the sinkers are independent and supported to move horizontally in suitable guides formed for them, for the sinking and drawing of the loops, and in which both narrowing and widening, commonly called fashioning, may be effected to the fabric during its manufacture by the aid of extra instruments.—Patent completed.

3821 W. N. NICHOLSON, Newark-upon-Trent. *Mangle.* Dated December 16, 1868.

This consists of two rollers of small diameter geared together with toothed wheels having a winch handle to actuate the same direct without any intermediate wheels.—Patent abandoned.

3822 W. A. VERREL and J. CAMERON, Glasgow. *Copper.* Dated December 16, 1868.

This consists in reducing the persalts of iron which attack and waste the iron afterwards used for inducing the precipitation of the copper to protosalts, by treating the solutions with sulphurous acid or gaseous mixtures containing it, such as may be obtained by burning sulphur or pyrites or other substance containing sulphur. This sulphurous acid combines with the surplus oxygen of the persalt, and in reducing such salt to a protosalt, is itself converted into sulphuric acid.—Patent abandoned.

3823 O. HOLLINGWORTH, Hereford-road. *Carriages.* Dated December 16, 1868.

This consists of making the body of the carriage of wicker work or other suitable light material, and of attaching thereto a hood of leather or other similar material with a movable driving box and dickey. When used as a park phæton, the hood is folded back on either side, and the dickey placed behind, with driving irons in the front. When used as a brougham, the hood is raised, doors are fitted in, and the dickey is removed to the front, to form a driving box for the coachman.—Patent abandoned.

3824 L. B. EVERARD, Leicester. *Drilling.* Dated December 16, 1868.

This consists of a cylinder with its necessary valve chest, valve piston, piston rod, guides, and slides, mounted on a metal ring, on opposite sides of which ring pivots are fastened, which work into bearings or carriages adjustable upon another ring, called the outer ring, which is made of a circular form, and arranged centrically with the cylinder.—Patent abandoned.

3825 T. O. FIDDER, Ventnor. *Railways, &c.* Dated December 16, 1868.

Each pair of wheels is mounted on a separate frame or truck, except in cases where it is expedient to mount two or more pairs in any one truck, and any number of such trucks, not less than three, are connected together to form one articulated frame. One such articulated frame may form the frame of a locomotive or traction engine or engines, of an engine and tender, of an engine and carriage or carriages, of a carriage or carriages, or of any waggon or waggons. For the purpose of coupling two or more pairs of wheels, or for the purpose of preventing vertical oscillations, or for the purpose of diminishing the load on each pair of wheels, two or more pairs of wheels may be mounted in any of the trucks, and when this is done, all the wheels in the truck, except one pair, may be without flanges.—Patent completed.

3826 L. DESENS, Charing-cross. *Safety lamps.* Dated December 16, 1868.

This consists in an improvement on the patent granted to the same inventor, No. 2891, dated September 19, 1868. The inventor lowers the gallery in the interior of the body of the lamp, so as to admit of the whole of the mechanism being closed in by the platform, which in this case is raised above the gallery, the object being to prevent any tampering therewith, and the more effectually to prevent the miners, in the event of their successfully opening the lamp, from relighting the same.—Patent abandoned.

3827 R. WAPPENSTEIN and R. RAY, Manchester. *Checking omnibus conductors, &c.* Dated December 16, 1868

For omnibuses, the inventors employ for each journey or stage of the journey, a double meter for the inside, and another double meter for the outside, one division of each meter being used for indicating the entrance, and the other the departure of the passengers, and in one or more conspicuous positions they place dials and fingers to be used as checks or tell tales. Each division of the meter is worked by a catch lever, put in motion by the hand or foot of the conductor, when a passenger enters and leaves the omnibus, each movement causing a bell to be struck and the indicating finger moved one division of the dial.—Patent abandoned.

3828 A. M. CLARK, Chancery-lane. *Ornamenting metals* (A communication.) Dated December 16, 1868.

The inventor takes any article in bronze, copper, aluminium bronze, or other metal or alloy, of a different colour to gold or silver, and paints on the surface in gonache colour any kind of ornamental design (flowers or figures) after previously cleaning the surface. This being done, the different parts of the surface not occupied by the design are next covered with a varnish, such as is used in aquafortis engraving, and the article is then placed in a bath of acetic acid at 12deg. Beaume in communication with the positive pole of a battery. The salt of lead of which the gonache colour is composed then dissolves, and the metal of which the article is composed is attacked. When the depth of the channels thus formed is considered sufficient, the article, after having been raised, is placed in a weak bath of cyanide of silver or gold, in connection with a battery. After the precious metal has become deposited in sufficient quantity, the operation is discontinued, and the varnish removed, after which, the article is polished by hand, so as to remove any excess of the metal inlaid, and make both surfaces perfectly level and smooth. The article is then bronzed, dark colours being chosen, in order to better bring out the gold or silver design.—Patent completed.

3829 J. WORRALL, Manchester, and J. KERSHAW, Wandsworth. *Stoves.* Dated December 16, 1868.

The inventors fit both stories with a railway to receive severally a lapping machine provided with flanged wheels to run thereon. In the frame or carriage of this machine they mount transversely a card roller, of a length almost sufficient to extend across the stove from one side to the other. One end of the cloth or other fabric to be introduced into the stove is led over this card roller, and by its rotation the cloth is lowered down for a certain distance between the transverse bars or rollers, which are intended to keep it suspended in the form of loose laps. The machine commences its operation at the far end of the stove, or the opposite end to that which it enters, and retreats step by step as it lays the cloth over the transverse bars or rollers.—Patent completed.

3830 T. AVELING, Rochester. *Steam cultivation.* Dated December 16, 1868.

The inventor proposes to construct the engines in pairs or as counterparts the one of the other, so far as respects the driving gear, so that the two engines when placed opposite each other in the field will both drive as well as draw from the land side—Patent completed.

3831 F. RYLAND, West Bromwich. *Lids.* Dated December 16, 1868.

This consists, first, in making the body and rim out of one piece of sheet metal. This is effected by first raising a disc or blank into the figure of a shallow cylindrical cup or dish, with a flat or slightly concave bottom, and applying pressure to the top of the cup or dish, so as to force out a flange or hollow ring near the bottom of the said cup or dish. The flange or hollow ring being flattened forms the projecting edge of the lid, which rests upon the top of the vessel with which the lid is used, the unchanged open end of the cup or dish forming the rim which fits in the vessel; the bottom of the cap or dish constitutes the top of the lid. The invention consists, second, in machinery or apparatus to be employed in the manufacture of the lids. The machinery or apparatus consists essentially of the following parts:—A die, fixed on the bed of a press or machine, is provided with a depression proper to receive the bottom of the shallow cylindrical cup or dish before referred to, which cup or dish is raised by dies and pressure, in the ordinary way. A plunger, of a size proper to fit accurately the interior of the cup or dish, has a rising and falling motion over the die, and upon the plunger a collar or ring slides. The upper part of the collar works freely but closely upon the plunger, while the lower part of the said collar is of somewhat larger internal diameter. There is thereby left between the lower part of the collar and the plunger an annular space, in which the upper part of the cylindrical cup or dish can enter.—Patent completed.

3832 S. C. LISTER, Manningham. *Boilers.* Dated December 16, 1868.

This consists in making the tubes of different materials, so that with equal temperatures the inner tube would expand more than the outer. It is preferred to make the inner tube of copper and the outer of iron. Also with the same object the inner or outer pipe is in some cases corrugated, also to reduce the strain resulting from any unequal expansion which may remain, and make the perforated connecting rivets longer than heretofore; they may advantageously be an inch and a half or more in length, and the patentee makes them of copper in place of iron.—Patent abandoned.

3833 G. RITCHE, Folkestone. *Compositions.* Dated December 16, 1868.

The inventor takes flock which has been reduced, cut, or ground to a short fibre, but sufficiently long to lay hold of the fabric upon which it is to be used, and to leave a proportion raised upon its surface. The fibre would thus vary from 1-24th part of an inch to 1-8th, or more, according to the purpose for which it may be applied. Having thus reduced or prepared the flock, the inventor mixes it with a cement of india-rubber, coloured or otherwise, and with or without varnish or gum. He reduces it to a consistence suitable for spreading upon surfaces by means of camphine or other well-known solvents, to which small quantities of a pigment, of proper colour and spirit, varnish or gum, may be added.—Patent completed.

3834 S. C. LISTER, Manningham. *Wool.* Dated December 16, 1868.

This consists in adapting and using, in treating such fibres, the intersecting screw gill, in which the gill teeth strike into the fibre in opposite directions, and subsequently carding or combing the fibre.—Patent completed.

3835 J. T. HALL, G. CRITCHLEY, Lancaster, and H. B. FOX, Chester. *Racks.* Dated December 17, 1868.

This consists in attaching to a hinge, or to any article where a hinge is required, a thin piece of metal of a segmental form, cut as a rack for nearly its entire length, one end of which is made fast and the other end wider than the racked portion, and which is guided by a fixed pin working in a slot of a piece of an irregular pentagonal form swivelled near its centre, the longest angle of which is a catch for the rack, and which is held in position by a spring or lever forcing it against the rack until thrown out of gear by the broader portion of the segmental piece, and which is restored to its working position by a pin striking it down upon a fixed piece, which also acts as a bearing for the catch piece, and the combination of the whole or part of these for the purpose set forth.—Patent abandoned.

3836 J. THORNILEY and G. WING, Massachusetts, U.S.A. *Files.* Dated December 17, 1868.

The inventors wash the files in a solution of warm water and concentrated potass until thoroughly cleansed, and then rinse them in warm water. They now put one pint of warm soft water into a wooden box, into which are put as many files as the water will cover, and then add to the above 2oz. of borax and 2oz. of blue vitriol, well pulverized together, to which they add 7oz. of sulphuric acid by weight. They now stir up the files and then add ½oz. of pure wine vinegar, after which the files become red, and when the files are stirred gently for a short time they resume their natural colour, and the restoring or renewing is completed.—Patent abandoned.

3837 G. HADFIELD, Lancaster. *Varnish.* Dated December 17, 1868.

The inventor takes about thirty gallons of turpentine and filters out or allow to subside the impurities, and removes the fifteen gallons of turpentine in excess of a much purer quality. These proportions will, of course, slightly vary according to the quality of the gum used and of the varnish required. He also takes varnishes prepared according to the ordinary process, and improves their drying properties by passing through them a stream of ozonized air or ozonized oxygen. This he prefers to do in a solution of them in an excess of turpentine, where the viscosity of the varnish will not permit of the use of this process without such dilution.—Patent completed.

3838 J. ROBERT-THEURER, Chause de Fonds, Switzerland. *Watches.* Dated December 17, 1868.

The bow of the watch instead of being, as usual, fixed to the case, is attached to a curved base or plate, corresponding to and fitting over the circumferential curve of the case. Into the bow one end of an arm is let, the other end of which is pivoted to the centre of the movement. This arm carries two pawls, which, by their engagement with the teeth of a ratchet wheel on the barrel arbor, effect the winding of a barrel if a to and fro movement be given to the bow.—Patent completed.

3839 A. PERRY, Dartford. *Windows.* Dated December 17, 1868.

This consists in placing artificial light with reflectors on the exterior of the building so as to produce a more brilliant light outside the window than on the inside of it, whereby the designs and colours will be effectually illuminated and will be seen from the interior of the building.—Patent abandoned.

3840 W. H. LENNOX, Hampstead-road, J. W. PEARMAN, and W. J. PEARMAN, Castle-street. *Printing music.* Dated December 17, 1868.

The inventors propose to employ a plate of soft metal or alloy, such as lead, pewter, or type metal without the addition of antimony, on which the lines required for music are to be engraved or cut, with the spaces between them for the impression of the notes. The plate is then to be stamped with dies of the various designs necessary to produce on the plate the notes and symbols of music printing, with the bars and the words of a song all reading the right way. After which a stereotype is to be made from the stamped or embossed plate. This stereotype may be composed of any suitable material or compound, but it is preferred to use ebonite on account of its firmness and the facility with which it may be moulded in a plastic form and pressed into the spaces cut in the plate, and when the ebonite has become hardened and set, the pressure is to be removed and the stereotype separated from the plate.—Patent abandoned.

3841 W. MANNERS, Nottingham. *Signals.* Dated December 17, 1868.

The inventor employs a pulley in form somewhat resembling a dolly peg, which is placed in a flanged socket, and is let through the top of a railway carriage into each compartment, as required. A rope, chain, or equivalent contrivance may pass through the signal pulley to the engine driver, to the guard, or to the engine driver only, and be attached to a bell or other alarm signal. These signal pulleys are fitted on a shaft, which passes through a socket placed in or near the top of the carriage.—Patent abandoned.

3842 G. H. BENSON and W. G. VALENTIN, Staleybridge. *Iron.* Dated December 17, 1868.

The inventors have discovered that the required temperature may always be maintained if the furnace be heated by a combination of highly heated combustible gases, and a blast of heated air introduced and maintained therein, under pressure, so as to prevent the ingress of the external air through any of the doors, cracks, crevices, or other openings in the furnace, and which air would lower the temperature of the furnace, and cause the molten iron to thicken, and their invention accordingly consists in heating the furnace as above indicated.—Patent abandoned.

3843 G. H. BENSON and W. S. VALENTIN, Staleybridge. *Manufacture of gas.* Dated December 16, 1868.

The inventors employ a close vessel or furnace, built of refractory material, such as firebricks, ganister, or other suitable material, and resting on columns. It may be built of a round, square, rectangular, or other suitable form or shape, and be provided with a hopper or hoppers for feeding the fuel. They prefer to make the portion of the furnace or gas generator which contains the upper portion of the fuel rectangular and oblong. The sides are inclined inwards at their lower part at an angle of about 45deg. These slopes or inclined planes are sometimes made of iron boxes, which can be kept full of water, and may be constructed either as close or open vessels.—Patent completed.

3844 T. INGLIS and T. INGLIS, War-Office. *Cylinders.* Dated December 17, 1868.

Cylinders or tubes constructed according to this invention are composed of at least two tubes, drawn the one over the other. The outer tube is formed of a close

helical coil of wrought iron, steel, or other metal, on the inner surface of which is cut a screw thread of quicker pitch than that of the coil, and running in the same direction. If two tubes only are used, the inner one may be either formed of a similar close helical metal coil or of a simple tube, a screw thread corresponding to that of the other tube being in either case formed on the exterior of the tube. The two tubes thus prepared are screwed together, care being taken, if the inner tube be a coiled one, that the coils of the outer and inner tubes shall break joint.—Patent abandoned.

3845 J. H. KNEVITT, Cornhill, and H. HAZARD, Cheapside. *Shutters, &c.* Dated December 17, 1868.

This consists in the peculiar means whereby the laths or slats are "louvered," or adjusted angularly to admit or exclude the light. The laths or slats are provided at one or both ends with two pins or projections. Each of these two pins or projections works in one part of a compound or double groove on the frame of the window, doorway, or other aperture. The compound groove is so constructed that the distance between the two parts of the same may be increased or diminished, as desired, to open or close the slats or laths, the laths being so connected or jointed together as to allow of their free division or action in louvering. In order to keep the two parts of the groove always parallel with each other, it is preferred to connect them by arms or links in the same manner as any ordinary parallel rule, or the adjustable part or parts of the groove may be provided with studs, which work in curved slots or guideways.—Patent completed.

3846 J. C. WALKER, Gainsborough-square. *Flour, &c.* Dated December 17, 1868.

This consists in producing an acid powder by diluting hydrochloric acid with water, until it attains a specific gravity of about 1·09deg. Beaume; this is poured into or sprinkled amongst any comparatively dry farinaceous or amylaceous substance, in the proportion of about 4oz. of the acidulated water to one pound of the farinaceous or amylaceous substance, rice flour. The flour as it is mixed with the acid water, should be stirred until the acid is thoroughly diffused throughout the mass. It is then run through a moderately fine sieve, to separate it from any sticky lumps it may contain, which are thrown aside as being unfit for use.—Patent abandoned.

3847 R. HALLIMOND, Bishop Auckland. *Lubricators.* Dated December 17, 1868.

This consists in adapting to the sides of a tub used in mining operations, an arrangement for lubricating the axles or bearings of the wheels on which such tubs run, so that each time the tub comes to "bank," a few drops of oil shall fall on to the bearings of the axles. A hollow vessel is formed of any shape, and with a hemispherical bottom, at the centre of which is a hole or seat into which fits a loose solid ball of metal or spherical valve. In connection with the aforesaid hole, other holes extend right and left and into these two holes pipes are screwed and fitted, each with a plug or valve for regulating the quantity of oil that shall escape or pass out on to the bearings of the axles, the outer and open ends of the said pipes being arranged immediately over the bearings of each axle.—Patent completed.

3848 J. QUICK and J. SAMPSON, Southwark. *Pistons* Dated December 17, 1868.

The block or body of the piston is formed with small holes or passages, the number of which may be varied to suit the size of the piston, and these small holes are properly packed and capable of moving therein, when influenced by any excess of pressure at one side of the piston over that at the other side. The apparatus is so arranged that in the normal position of these small pistons, any change in pressure on the respective holes or passages in the block or body of the main piston, will be communicated from them through the cap top plate or junk ring of the main piston, or through suitable T-pieces or equivalent devices, to the packing ring or rings, so as to force the latter against the inner surface of the cylinder.—Patent completed.

3849 F. POUNCY, Dorchester. *Printing pictures.* Dated December 17, 1868.

The inventor first applies the required monochrome colour all over the surface of the material on which the picture is to produced, and the negative is then to be applied to the prepared or non-prepared surface, when the light hardens the colouring matter, the parts not acted upon by light remaining soluble, and are to be dissolved off, either by spirit or water, or both, according to the nature of the preparation of the paper or surface on which the picture is produced. The solution to be adopted for giving transparency to the paper or other material used, consists of oil or other matter, such as oils, wax, and glycerine, it not being necessary always to use all these ingredients.—Patent completed.

3850 C. LIEBERMANN and C. GRAEBE, Berlin. *Colouring.* Dated December 18, 1868.

The following is the manner in which it is preferred to proceed for preparing the anthrakmon or oxanthracene. The inventors take 1 part of anthracenie 2½ parts by weight of bichromate of potassium, and from 10 parts to 15 parts of concentrated acetic acid, and heat these substances together in a vessel, either of glass or clay, to from 100deg. to 120deg. Cen., till nearly all the bichromate of potassium is dissolved, and the liquid has acquired a deep green colour. They then recover the acetic acid not consumed in the reaction by distillation, and treat the residue with water to remove the chromic acetate. From the insoluble mass they obtain the anthrakmon in a pure state, by distilling the whole in a retort of glass or iron.—Patent completed.

3851 E. T. HUGHES, Chancery-lane. *Vessels.* (A communication). Dated December 18, 1868.

This consists in arranging cylindrical or other suitably shaped bodies beneath and partially above the water line of such vessels, and either at the bow, stern, or other desirable position.—Patent abandoned.

3852 E. T. HUGHES, Chancery-lane. *Urns.* (A communication). Dated December 18, 1868.

This relates to a patent, dated November 28, 1867, No. 3370, in an urn in which the tea or coffee is drawn through a cock or faucet; it is now not found necessary to tip the urn, hence the communication from the water joint out or down is not required.—Patent abandoned.

3853 J. W. BRIERLEY, Oldham. *Nuts.* Dated December 18, 1868.

This consists in a machine which, by the simple movement to and fro of a headstock upon a slide or bed shapes, flattens and cuts off the nuts from a heated bar and delivers them sufficiently hot for the workmen to finish them with a few strokes of the hammer on a "swage" of suitable form attached to the anvil. The machine consists mainly of three parts, viz., a bed or slide, a fixed headstock, and a mowing headstock. The latter slides to and fro on the bed, and is actuated by means of an eccentric cam or crank on the main driving shaft which revolves with a slow motion.—Patent completed.

3854 W. F. THOMAS, Cheapside. *Sewing machines.* Dated December 18, 1868.

This relates to a patent, dated June 20, 1867, No. 1798. In place of arranging the awl, so as to enter the leather or other material on the same side as that on which the needle enters it, the inventor now causes the awl to enter on the opposite side, that is, on the same side as that on which the shuttle or equivalent contrivance is situated. Or he arranges the needle and awl on the same side of the material, in combination with a shuttle on the other side, and he carries them by a slide or by two separate slides to which a reciprocating lateral motion is imparted, so that by such motion, the awl and needle are consecutively brought over one and the same place.—Patent completed.

3855 J. HODGSON, Bradford, H. BOTTOMLEY, Low Moor, E. COCKCROFT, Bradford. *Weaving.* Dated December 18, 1868.

The improvements relate to means by which rotary motion may be given to rotary shuttle boxes, containing in the order desired series of shuttle chambers with capability for missing or "skipping" one or more of the shuttle chambers, in the selections of the shuttle to be brought into use. For this purpose, there are clawker rods to act one on each side of a stud or peg wheel, affixed on the end of the series of shuttle boxes or chambers, to cause them to make partial rotation in either direction, and each of these clawker rods is connected to one end of a separate lever, the other end of which is connected to a separate rod, extending by preference upwards, and these rods have formed on each of them a notch or projection adapted to be caught, so as to raise these rods by one end of a lifting lever, actuated by tappet or otherwise, in order to be lifted when they are brought into contact with it, during its rising motion.—Patent completed.

3856 E. T. GRIFFITHS, Sheerness. *Anchors.* Dated December 18, 1868.

A pennant is employed, one end being attached to a shackle on the anchor, and the other end attached by a loose shackle to the cable. When the anchor is weighed, the pennant passes with the cable through the hawse pipe; the pennant is then released from the cable, and attached to a rope, by which it is drawn back out of the hawse pipe; by then hauling on this rope, the anchor is raised up to a davit, which has a block over which the rope passes; the anchor can then be stowed on board. The pennant may have a long link about its middle for use if the anchor fouls. The anchor may be suspended by a slip stopper.—Patent completed.

3857 T. B. SALTER and J. SILVESTER, West Bromwich. *Steam gauges.* Dated December 18, 1868.

The inventors fix the axis on which the index finger turns to the back of the case. Another axis is fixed to the back of the case on which an arm or lever turns in a plane parallel to that in which the index finger works. On the under side of the bush of the index finger is a slot in the direction of a radius from the centre of the bush. A pin on the end of the arm or lever described engages in the slot, and a slight motion in the arm or lever, causes the pin on its end to act on the bush of the index finger and move it through a considerable angle. A rod, bearing at one end against the corrugated or other plate deflected by the pressure, and at its other end against the arm or lever, transmits motion from the former to the latter. By this arrangement, the motion of the said plate is transmitted to and largely multiplied in the index finger. In gauges, in which the pressure deflects a flat tube, the inventors fix the axis on which the index finger turns on one end of the tube, and they fix the pin which engages in the slot in the bush of the index finger on the other end of the tube. Or they fix the axis of the index finger to the case of the instrument, and the pin to one end of the tube.—Patent completed.

3858 J. EDRIDGE and J. MERRELL, Birmingham. *Pins.* Dated December 18, 1868.

The inventors dispense with the use of acid or cleaning solutions or fluxes in solution and they use a dry flux, namely, powdered salammoniac. The pins or articles, on leaving the machine in which they are made, are simply cleaned in dry sawdust, and transferred to the tinning pot, where, by the use of salammoniac, the proper adhesion of the tin is secured.—Patent completed.

3859 S. REMINGTON, Ilion, New York. *Firearms.* Dated December 18, 1868.

The inventor takes a tube of sufficient length to form two or more shoes, and of the proper diameter and calibre. The tube may be formed of any of the present known methods of making metallic tubing. The said tube is then bored throughout its entire length to the proper size to receive the breech bolt, and is also turned on its exterior. He then cuts the tube into pieces or sections of the required length to form the shoes. Apertures may be made in the shoe for admitting the cartridges, and for allowing the handle and other projections of the bolt to move in the required directions, and the end of the shoe may have a screw thread cut in it to secure the end of the barrel in the ordinary manner. The tail or tang of the shoe may also be shaped and adapted to the stock and to the breech mechanism as required.—Patent completed.

3861 T. SPENCER, Bolton-le-Moor. *Yarn.* Dated December 18, 1868,

This consists in an arrangement of shafts, wheels, and pulleys, fixed in a frame, and principally of a new form of spindle box and spindle and apparatus, and appliances for working the same, and has for its object the saving of room and space and the substitution of the spinning and roving machinery now in use.—Patent completed.

3862 G. D. ROBINSON, Gray's Inn-road. *Carriages.* Dated December 18, 1868.

This consists in making one half or a portion of the front seat movable, so that access to such seat may be obtained from the rear of such vehicles, by simply moving such portion of the seat and replacing the same.—Patent abandoned.

3863 E. P. H. VAUGHAN, Chancery-lane. *Rosin oil* (A communication). Dated December 18, 1868.

This consists in incorporating with the rough or crude oils produced by the distillation of pure rosin a quantity of lime or other oxide of the alkaline or alkaline earthy metals, such as potash, soda, and magnesia, and then submitting the mixture thus formed to distillation. By this treatment the impurities contained in the rough or crude oil remain, in combination with the lime or other reagent employed, whilst the oils distil over one after another, according to their several densities, in a state of purity. The quantity of lime or other reagent employed in this process depends on the degree of impurity of the rough or crude oils under treatment, but, as a general rule, should be about 1-10th part by weight of the latter.—Patent completed.

3864 E. PAVY, Paris, and J. CLARK, Manchester. *Treating yarns and fabrics.* Dated December 18, 1868.

This consists in a chemical treatment of fibrous materials, such as jute, china grass, and cotton, either in the raw state or when made into yarn or cloth, whereby the fibre is deprived of glutinous, resinous, or other such matters, and is in a certain degree disintegrated. The inventors take the raw material, yarn, or woven fabric, and boil it from three to four hours in caustic alkali, of the strength of about 2½deg. Twaddell, after which the material is washed in either hot or cold water. They now immerse the material in a weak solution of sulphuric acid, say one pint to 100 gallons of water, and allow it to remain for about half an hour, and then wash with water. After this they boil the material for about an hour in soap and water, say 20lb. of soap to 100 gallons of water, and then repeat the washing in water. They then steep the material for about half an hour in a solution of sulphate of ammonia, of the strength of about 5lb. of the sulphate to 100 gallons of water, again repeat the washing, and when dry the materials are ready for bleaching, dyeing, or printing. The following is another treatment which they have found to answer. The materials are boiled from one to three hours in a mixture of water and muriatic, sulphuric or nitric acids, in proportions, say, from one to five pints to 100 gallons of water, or the materials may be immersed from one to three hours in the same mixture the solution being cold. The materials are then washed and may be treated with a weak solution of alkali to get rid of the last traces of acid. After washing and drying the materials are ready for bleaching, dyeing, or printing —Patent completed.

3865 J. PETRIE and W. T. CHEETHAM, Lancaster. *Warming apartments.* Dated December 18, 1868.

This consists in the use of steam at atmospheric pressure, or substantially so, for heating and evaporating purposes. The inventors employ a boiler which is fed with water by an adjacent vessel, the communication between the two being always open, and the water level being the same in the said boiler and vessel; and to maintain this condition they use an outlet of sufficient area to allow the passage of the steam as it is generated, and it may flow through pipes or other ordinary apparatus used for heating purposes.—Patent abandoned.

3866 M. BROWN, Westhead, and R. SMITH, Lancaster *Threads.* Dated December 18, 1868.

The inventors employ, first, a clip or drag, which is capable of revolving and also of traversing the length of the bobbin, spool, or other surface. One method they propose is to employ a bead or eye, through which the thread or twine is passed twice, and in another arrangement they pass the thread or twine once through a bead or eye, which is drawn towards the bobbin, spool, or other surface by an elastic ring or other medium According to another plan, they supply the bobbin, spool, or other surface with a spindle carrying an arm, through which the thread or twine passes. This spindle being held by hand or otherwise, when the thread or twine is being drawn off the bobbin or other such surface, is caused to revolve while the said arm retains the end.—Patent abandoned.

3867 H. E. LEROY, Paris. *Obtaining publicity.* Dated December 19, 1868.

This consists in placing in juxtaposition to the front and back of a sheet of thick paper another sheet of stout paper, embellished with various ornaments and designs and cut out in geometrical or fanciful figures, under each of which openings is placed a sheet bearing the advertisements. The cut-out sheet on both faces of the intermediate and uncut sheets and this latter are kept together so as to form but a single and same sheet by means of strips of stout paper pasted on three sides of the margin, and traversed on the fourth side by two screws with studs screwing on both faces of the sheet, so that to introduce the cut-out sheet and the advertisements and place them in juxtaposition on the intermediate sheet it is only necessary to unscrew these two studs. Each sheet thus prepared is fastened to another similar sheet so as to form a twin sheet by the aid of a double band of linen in which is a strip of stout paper, arranged so as to form a joint and permit the volume when open to remain perfectly flat. Each twin sheet is then sewn by the linen band to the back of the cover of the volume or album. —Patent abandoned.

3868 J. BRIERLEY, Blackburn. *Ventilation.* Dated December 19, 1868.

An earthenware or other material vessel of cylindrical or other form, having two branch arms thereto, the one connected with the drain as usual and the other above the highest water line in the trap, is connected with a "stain pipe," or pipe specially arranged and employed for conducting the noxious gases to a safe point of discharge. It is preferred to have a pipe specially arranged for the purpose of discharging the gases, and provided with a receptacle for charcoal or other deodorant through which the gases pass on their way to the point of discharge. The lid or cover of the trap is provided with a pipe of such length as at once ensures the proper degree of immersion, it being no longer dependent on the care of the workman; all that is required is, on the trap being fixed, the insertion of the end of the sink or other pipe in the pipe attached to the lid of the trap, which pipe is conical or bell mouthed to facilitate the introduction of the sink pipe into the same.—Patent abandoned.

3869 M. S. MAYNARD and R. GRIME, Preston. *Motive-power engines.* Dated December 19, 1868.

This consists in combining the actions of two governors, one of which becomes stationary only at the required speed, but continually changes its position so long as that speed is deviated from, and is therefore commonly called an isochronal governor, and the other takes a definite position corresponding to and depending on the rate of speed, a type of which is to be found in the ordinary ball governor. One arrangement of parts for carrying on this

invention consists of a lever hereafter described as the "combination lever," one part of which is attached to, or otherwise connected with, the throttle or other valve or starting gear; a second part of the lever is similarly connected with the first named or isochronal governor, and the third part of the lever is also similarly connected with the last-named or ordinary ball governor. By this means the throttle or other valve or starting gear partakes of the joint motion of both these governors, thereby securing a better governing action. A second arrangement consists of a weight placed upon a horizontal lever attached to the rocking shaft connected with the ordinary governor, this weight being made to slide or change its position upon the horizontal lever by the action of the isochronal governor, thus assisting the balls of the ordinary ball governor to rise or fall, and so move the throttle or other valve or starting gear as may be required.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated June 29, 1869.

1958 G. C. Haswell, Edinburgh. Improvements in water directors for fire engines, garden engines, and hose, and for nozzles for force pumps.

1959 C. L. V. Yon, Boulevart de Strasbourg, Paris. A new kind of portable camping trunk, containing in a small bulk a light tent with all the required furnitures and implements necessary for military, rambling travellers, and emigrants.

1960 W. Cowan, Kittybrewster, Aberdeen. An improvement in locomotive engines.

1961 W. Blackburn, Manchester. Improved standards or supports for branches, desks, and tables.

1962 E. T. Hughes, Chancery-lane. Improvements in the manufacture of sugar, and in apparatus employed therein.

1963 W. Bartram, Sheffield. Improvements in apparatus for filling and closing cartridges.

Dated June 30, 1869.

1964 H. Yates, Rue Lafayette, St. Pierre les Calais, France. Improvements in means or apparatus applicable to bobbin net or twist lace machinery, or other machinery arranged and operating in a similar manner.

1965 R. H. Courtenay, Meyrick-road, Clapham Junction, Surrey. Improved processes for producing printing surfaces.

1966 B. Templar, Holly Bank, Tetlow Fold, near Manchester. A combined apparatus for damping and cleaning slates, sharpening slate pencils, and wiping pens.

1967 M. Turnor, Birmingham. Improvements in the manufacture of metallic and other boxes.

1968 R. Brown, Glasgow. Improvements in the manufacture of iron, and in apparatus therefor.

1969 W. E. Gedge, Wellington-street, Strand. An improved carriage spring.

1970 W. E. Gedge, Wellington-street, Strand. The incorporation of extract of meat with all kinds of sweetmeats or comfits, with syrups or any sweet or glucose matter, with quinine wine, and all kinds of wines prepared with quinquina.

1971 D. Hebson, Liverpool. Improvements in steam engines.

1972 R. Knowles and J. Lindley, Manchester. Improvements in the manufacture and ornamentation of ladies' night-dress cases, bed-head bags, watch pockets, and other similar articles.

1973 R. Heyworth, Manchester. Improvements in water-closets, wash basins, and urinals, and in self-acting apparatus for the same.

1974 W. H. Bailey, Albion Works, Salford, Lancashire. Improvements in cutting and slicing machinery, and in adjustable feed apparatus therefor.

1975 R. Boyd, Strand. Improvements in switches and signals, and in the mode of working same.

1976 J. Robinson, Martin's-lane, City. Improvements in means or apparatus for preserving animal and vegetable substances.

Dated July 1, 1869.

1977 A. Walker, Heriot, Mid Lothian. Improvements in agricultural implements.

1978 W. E. Gedge, Wellington-street, Strand. An improved safety brake for railway vehicles.

1979 R. W. Whitehead, Ashton-on-Mersey, Chester. Improvements in coupling or jointing pipes or tubes.

1980 W. Coleman, City, and S. Turton, Heaton Norris, Lancashire. Improvements in feeding bottles.

1981 R. Porter, Birmingham. Improvements in furnaces.

1982 T. Atwater, Paris. An improved band for ladies wear.

1983 J. Stringfellow, Chard, Somersetshire. Improved apparatus for affording protection from bullets and other missiles.

1984 J. D. Dougall, St. James's-street, Westminster, and W. Bartram, Sheffield. A new or improved apparatus for filling cartridges.

1985 J. H. Johnson, Lincoln's Inn-fields. Improvements in breech-loading firearms.

1986 A. Barclay, Kilmarnock, Ayrshire. Improvements in motive-power engines.

1987 L. F. Banks, Royal Hospital, Kilmainham, Dublin. Improvements in markers for the game of croquet.

1988 A. V. Newton, Chancery-lane. An improved manufacture of nail or spike, and machinery for making the same, which machinery is applicable to the forming of bolts and spikes of the ordinary construction, and other articles having screw threads, and also to the straightening of shafts, rods, and pipes.

1989 A. Turner, Leicester. Improvements for utilizing waste strips of india-rubber.

1990 H. Larkin, Torriano Cottages, Leighton-road, Middlesex, and W. White, Thurlow-road, Hampstead, Middlesex. Improvements in the production of sodium and potassium.

1991 E. Roe, Nottingham. Improvements in the manufacture of looped or knitted fabrics, and in the machinery or apparatus employed therein.

Dated July 2, 1869.

1992 T. Jones, Handsworth, Staffordshire. A new or improved method of attaching or uniting together the body and barrel of repeating firearms.

1993 H. A. Bonneville, Sackville-street, Piccadilly. A new and improved billiard and bagatelle room convenience.

1994 H. A. Bonneville, Sackville-street, Piccadilly. A new and improved motive power.

1995 E. Scott, Manchester. Improvements in weighting motions used in machinery for preparing, spinning, twisting, and doubling fibrous materials, and for other similar purposes.

1996 S. Smithson, Heckmondwike, Yorkshire, and G. Senior and J. Inman, Brighouse, Yorkshire. Improvements in valves or valve taps for regulating the discharge or flow of water or other fluids or gases.

1997 S. Brooke, Brighouse, Yorkshire. Improvements in, or applicable to, machinery or apparatus for carding and otherwise preparing wool or other fibrous substances for spinning.

1998 G. White, Queen-street, Cheapside, City. An improved rotary steam engine.

1999 O. D. Abel, Southampton-buildings, Chancery-lane. Improvements in the mode of, and materials for, preparing corks for rendering them impermeable under the action of wines and other liquids, either when charged with gases or not.

2000 H. Turner, jun., Leicester. Improvements in weaving plain and elastic terry fabrics.

2001 W. Frazer, East Parade, Newcastle-upon-Tyne. Improvements in the preparation of materials for fettling or lining puddling furnaces, and other like uses.

2002 W. R. Lake, Southampton-buildings, Chancery-lane. An improved combined travelling bag and chair.

2003 J. Smithers, Dawson-street, Dublin. Improvements in galvanic batteries.

2004 W. A. Biddell, Edward-street Parade, Birmingham, and J. Redgrave, Newhall-street, Birmingham. Improvements in the manufacture of ornamental articles in glass alone, or in combination with other materials, and in the application thereof to various purposes.

2005 A. V. Newton, Chancery-lane. Improvements in preparing flax, hemp, and other fibres, and in converting the same into slivers.

2006 H. E. Newton, Chancery-lane. Improvements in meters for measuring liquids.

2007 J. Steward, Wolverhampton. Improvements in pianofortes.

2008 Alfred Foucant, Orleans, France. Improvements in telegraphic cables.

Dated July 3, 1869.

2009 P. G. Gardiner, New York, U.S.A. Improvements in springs for railroad cars, buffers, and various other purposes.

2010 N. Mole, Calvert-street, Shoreditch, Middlesex. Improvements in boots and shoes.

2011 A. Angell, Rio Janeiro, Brazil. Improvements in machinery for hulling and polishing coffee, rice and other berries or seeds.

2012 A. H. A. Durant, Avenue-road, Shepherd's Bush, Middlesex. Improvements in the mode or means of preparing or treating castor and other oleaginous seeds or berries for the manufacture of oil, and in the manufacture of oil from the seeds or berries so prepared or treated.

2013 T. Grahame, Lansdowne-place, Leamington, Warwickshire. Improvements in the construction of barges, boats, floating batteries, and other floating structures.

2014 I. James, Cheltenham, Gloucestershire. Improvements in machinery or apparatus for crushing or breaking stones, bones, and other hard substances.

2015 G. Palmer, Reading, Berks. Improvements in the manufacture of biscuits.

2016 J. Hart, Leamington, Warwickshire. Improvements in the mean of, and apparatus for, separating, distributing, and utilizing sewage.

2017 T. Butler, Nottingham, and R. F. Carey, Nottingham Park, Nottinghamshire. Improvements in the manufacture of lace made on bobbin net or twist lace machines.

2018 C. Churchill, Darnley-crescent, Hackney, Middlesex. An improved implement for drawing nails.

Dated July 5, 1868.

2019 J. Clark, Paisley, Renfrewshire, and A. Ewing, Glasgow. Improvements in feeding steam boilers or generators, and in the apparatus or mechanism employed therefor.

2020 T. Smith, Birmingham. An improved means of utilizing the waste heat of puddling and ball furnaces for the calcination of cinder into bulldog for furnace fettling, and an improved means for preventing the adhesion of the same substance in large masses.

2021 W. Duckworth, jun., Liverpool. Improvements in taps for general purposes.

2022 F. W. Grune, Berlin, Prussia. Improvements in transferring photographs to wood, metal, ivory, and other surfaces.

2023 T. Wilson, Birmingham. Improvements in constructing and working velocipedes.

2024 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in water meters.

2025 L. Falisse, Liege, Belgium. An improved breech-loading firearm.

2026 W. E. Newton, Chancery-lane. Improvements in the manufacture of bar iron, and in the machinery for rolling the same into various forms.

2027 J. Knight, Huntingdonshire. Improvements in four-wheeled vehicles.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 2, 1869.

24 L. Hannart
26 W. Prosser
27 E. W. and J. Voce

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, JULY 16, 1869.

THE FAIRLIE STEAM CARRIAGE.

THE name of Mr. Robert F. Fairlie has, for some time past, been brought prominently before the public in connection with the economical working of railways. The Fairlie engine is well known to our readers, and a brief description of his steam carriage has also appeared in our pages. A trial of this carriage—details of which we reserve for next week—was made yesterday, at the Hatcham Iron Works, which successfully demonstrated the practicability of working the system upon railways, with curves of only 50ft. radius. The steam carriage exhibited yesterday, and which was not quite completed, was designed to work on a metropolitan railway, at the terminal stations of which sufficient space could not be given for laying down rails on a curve of 25ft. radius for the standard carriage to run itself round; consequently, the standard carriage had to be altered in dimensions to allow of its being turned on an ordinary 40ft. turntable. Hence, instead of seating, as is intended, the 100 passengers in the standard carriage, the carriage under trial only gave seating space for sixteen first class and fifty second class, in all 66 passengers. The accommodation per passenger is as good as is given on the best lines, and infinitely superior to the stock usually worked on branch lines. The length of the carriage is 43ft., including a compartment near the engine for the guard. The engine, carriage, and framing all complete, in working order, but exclusive of passengers, weighs under 13½ tons, and including its full load of passengers 18½ tons only. The carriage when finished complete will have a broad step or platform on each side, extending its entire length; this step is protected by a hand rail on the outside, with an arrangement for lifting it on the platform side at the doors to allow the passengers to get in and out. The object of this platform is to enable the guard to pass completely round the train at all times, and while doing so, he is perfectly safe from any accident. Passengers can also pass along the platform to the guard, so that in this manner there is an easy and perfect mode of communication between passengers and guard.

It is intended, however, in the standard steam carriage to provide a central passage inside the entire length of the carriage, leading direct from and to the guard's compartment; thus there is the most direct means of communication between the passengers and guard. The compartments in the carriages will be quite as separate and distinct as they are at present, or as the most fastidious could desire. The guard passes through the carriage at pleasure. Those in the higher classes can pass to the lower, but the lower cannot get to the higher, while all can pass to the guard when required. The standard carriage will have two compartments first class, to seat 16 persons; three compartments second class, to seat 30 persons; and four and a-half compartments third class, to seat 54 persons—in all, 100 passengers. The machine complete, in working order, will weigh about 14 tons, and with the 100 passengers, from 20 tons to 21 tons. These carriages will convey their full complement of passengers at forty miles per hour up gradients of 1 in 100, and, as demonstrated, will pass round curves of 50ft. radius at twenty miles an hour with perfect safety.

There are few trains on any of our railways which convey more passengers per mile than can be accommodated by one of these steam carriages. In fact, it is known that the average number of passengers, taken from the Parliamentary returns, give only about eighty passengers conveyed altogether by each passenger train in the United Kingdom, from the time it starts until it completes its journey; and this only gives about an average of 30 to 35 passengers at any one time in the train, for each mile travelled. Of course, there are exceptions to this number on our principal main lines, but even in these cases, a greater number is the exception, and not the rule. The weight per wheel of the steam carriage being only about 2½ tons, it follows that very light rails may be used, with everything light in proportion. The passage of such sharp curves so easily will enable us to make lines very inexpensively; we need no embankments or cuttings or heavy masonry works of any kind; therefore, lines will be made cheaply and stocked cheaply. Under these circumstances, there is no reason why every village should not have its line either direct or in communication with some of the main lines, to which these light railways would act as feeders, and not like the present branch lines, which really act as suckers and not feeders. Many of these branch lines have actually cost a larger sum per mile than the parent line, over which the traffic from the particular branch would not represent more than 5 per cent., if so much, of the total traffic. Then how, in the name of wonder, can such lines pay? When a gentleman desires to open up an estate for building or agricultural purposes, the first thing he considers is the making of suitable roads through it. Now, instead of roads, there is no reason why these light railways should not be made. In time it will come to this.

We are only, in a sense, beginning railways; we must have double, aye, treble the mileage we have at present, but everyone of these miles must not only be constructed but worked in a very different manner to that in which they have been, and are being at present. We have only to consider this simple fact: the steam carriage, with 100 passengers included, weighs about 20 tons, while the tender which accompanies the ordinary locomotive, and which is perfectly useless, except to carry food for the locomotive, weighs as much, if not more. The usual passenger trains average in weight, exclusive of passengers, about 80 tons; therefore, it follows if to work 80 tons it takes 30lb. of fuel for the locomotive per mile, to work only 20 tons one-fourth of the fuel would be required. The reference to fuel means oil, tallow, and every material required to maintain the engine; it means also the same proportionate reduction in the cost of maintenance of permanent way, and all charges connected with the working of railways. The proper method of working railways is to take the largest possible loads, and, consequently, fewer numbers of goods trains; so that instead of earning about 6s. per train per mile at a cost of 50 per cent., netting 3s., these should earn double the amount—say 12s. per mile—while the cost would not exceed 1s. over the 3s. spent to earn the 6s., giving a net production of 8s., instead of 3s., or about 280 per cent. more.

Then, again, the passenger trains which now earn under 5s. per train per mile, and costing 50 per cent. of the amount, or 2s. 6d. to earn it, could be worked with the steam carriages at a cost of about 1s. 6d. per mile, thus adding 40 per cent. to the net receipts on passenger traffic. It is to be remembered that these percentages are pure gains to railway companies, the cost of management and other charges being taken as remaining the same, the profits arising solely from the improved mode of working. The Fairlie engine can haul double the ordinary loads of goods per train, without injuring the permanent way so much as is now done by the ordinary engine; and allowing for the increase in the consumption of fuel for the load taken, all other expenses remaining the same, the extra cost on each train could not exceed even 6d., although 1s. is placed against this item—therefore the profit must certainly be very great.

While on the subject, we may notice the Fairlie engine "Little Wonder," which has been built for the Festiniog Railway Company, and which has obtained very considerable notoriety from its being the narrowest gauge passenger railway worked by locomotives in existence. The line has been worked now about five years, and during that time there has not been the slightest accident of any kind; in fact, it is considered a most extraordinary line, not only on account of its gauge, which is only 2ft., but because of its success commercially. The traffic hauled last year over this miniature line of twelve miles in length amounted to 130,000 tons of goods, and 145,000 passengers, which would be considered a very handsome traffic for a full-sized railway of the same length, and the wonder is, how it has been done. The credit is due to the able management of Mr. C. E. Spooner, managing director and engineer. The traffic has so increased that the ordinary engines are getting too small to pull the loads, and hence the adoption of the Fairlie engine, which at once enables the train loads to be doubled, without, but in a very small degree, increasing the cost of each train. The Festiniog line is, for about eleven miles, one continuous ascent of about 1 in 80, with very many curves, some of which are as small as 100ft. radius. The "Little Wonder," although weighing but 19½ tons, fully equipped with fuel and water for the road, will haul after it 140 tons, at a speed of fifteen miles an hour for the whole eleven miles; a feat, considering the gauge and weight, that could not be accomplished by other than the Fairlie engine. The engine has eight wheels, in two separate groups of four each, each group being acted on by a pair of cylinders 8½in. diameter. The wheels in each group are 2ft. 4in. diameter, and are coupled together.

The extreme wheel base is 18ft.; consequently, the engine will run with remarkable smoothness. At the same time, the wheel base of each bogie being but 5ft., the engine will pass round curves of 50ft. with the utmost safety at 20 miles an hour. The principle in this respect is precisely similar to that of the steam carriage passing curves of 50ft. The fact of either steam carriages or engines being constructed to run with perfect safety round curves of 50ft. is unprecedented in the history of railways, and places the railway world under a considerable obligation to Mr. Fairlie, who has spared no pains to perfect a system to which we wish every success.

THE ROYAL AGRICULTURAL SHOW AT MANCHESTER.

THE thirtieth annual meeting of the Royal Agricultural Society is held this year at Manchester. Old Trafford, the locality in which the show will take place, is two and a-half or three miles from the centre of the city, and within a comparatively limited radius there has been found not only abundance of accommodation for the show yard proper, but also a farm upon which over 100 acres of rye, grass, clover, and winter oats were ready for the implement trials. The show ground extends over a length of three-quarters of a mile, and is on the western side of the South Junction Railway; the crops being situated on the other side of the line. Last year, at Leicester, the competition was in ploughs and implements of culture. This year, the trial is for mowing, reaping, and haymaking machines. There is also a ploughing competition, in which all the best plough makers are represented. The trials of mowing and reaping machines commenced on Mon-

day last. Many of the reaping machines were new, and showed much ingenuity in cutting and in self-delivery. The judges selected thirteen reaping machines with self-delivery in swathe, eighteen reaping machines with self-delivery in sheath, nine reaping machines without self-delivery, and eighteen are horse reapers, to take part in the trial. The mowing machines were tried in a large rye-grass field some distance from the barley upon which the reapers were tried. There were twenty-five machines, each of which in rotation mowed half an acre in the presence of the judges. The final decisions will be known at the end of the week. On Monday next, the entire show yard will be opened at eight o'clock in the morning, when we shall be able to obtain all particulars of novelties in machinery, and place them before our readers in due course, as usual. The show is expected to be one of the largest the Society has held. There are 365 exhibitors and 7,724 entries, and the catalogue occupies over 500 pages. If our readers, who intend proceeding to the show from London, follow our course they will proceed by the Midland Railway, which will deposit them in the centre of Manchester, which they will make their head quarters. There are ample means of conveyance to Old Trafford, and in Manchester there is much to be seen in the way of spinning machinery that would alone repay a visit to the Cotton City.

WIMBLEDON, 1869.

WIMBLEDON Common presents the usual features which have been given to it for several years past by the proceedings of the National Rifle Association. The Queen's prize has this year been carried off by Mr. Cameron, who won it in 1866 with 69 points, but who has this year made the unprecedented score of 71 points. The breech-loaders are not in such full force as they were last year, but some excellent shooting has been made with them. Of course, the Martini-Henry was there, as well as the Henry rifle. There were also a Westley-Richards, a Carter and Edwards, and a Soper rifle. There was also a new rifle of very simple construction, by Mr. Restall, which we shall describe fully upon another occasion. The Martini-Henry made some good scores, although, on more than one occasion, we noticed miss-fires, and twice in thirty-eight rounds the top of the exploded cap came off and jammed the breech-block. These mishaps were entirely owing to the cartridge—the Boxer pattern—and were in no way attributable to the rifle itself. Some excellent shooting was done with the Henry rifle, especially by Mr. Farquharson at 800 yards. At other ranges its superiority also showed itself, notably at the 200 yards. With the Westley-Richards-Henry some excellent shooting was made at this range by Sir C. Shakerley, who scored in the three minutes four bull's-eyes, seventeen centres, and twenty outers, equal to 107 points; and at the 500 yards, with the same rifle, he made one bull's-eye, seventeen centres, and twelve outers, his score showing forty-one shots seventy-nine points. Captain Burt also tried a Westley-Richards-Henry and made eighty-four. Pace, with the Henry, scored eighty-seven, and there were other scores nearly as good. The Soper-Henry was fired for the first time at 207 yards, and made 103 points. In the 200 yards breech-loading competition some excellent scores were made on Wednesday, the highest being that of Mr. Hay, of the London Scottish, with the Martini-Henry rifle, who fired forty-four shots in the allotted time (three minutes), making eleven bull's-eyes, nineteen centres, and fourteen outers, total 127; this is the highest score which has been made in this competition. Serjeant Gilder scored 124 points, firing thirty-eight shots; his score as shown by the butts was 128, but it appears that through some misunderstanding the disc indicating five shots was exhibited instead of that indicating three, thus giving Serjeant Gilder two shots more than he actually fired; the mistake has, however, been rectified, and his score stands at 124. Serjeant Frost, of the 26th Kent, scored 110 points in forty-seven shots; the foregoing scores are for the Martini prizes. For the Duke of Cambridge's prize 113 has been scored with the Soper direct-action rifle, in forty-six shots; and with the same rifle, the extraordinary number of fifty-four shots in the three minutes has been made by Serjeant Warwick, scoring, however, only 111 points.

On leaving the camp, our attention was attracted to three boilers—two vertical and one horizontal—at the back of Messrs. Spiers and Pond's capacious refreshment department. These boilers, we found, on enquiry were used to supply steam to the cooking department. By the courtesy of the proprietors, we inspected the arrangements for providing the camp with sustenance. The ice room, in which the ice, beer, and provisions are stored for use, is partly excavated in the earth and partly constructed of walls 2ft. thick made of earth and boarded, the roof being formed in the same way. The cooking and other departments are well arranged, and every facility is afforded for supplying the demands of the appetites that present themselves from early morn to late at night. The pressure on the resources of the establishment is sometimes very great. For instance, on Saturday and Sunday last, we were informed that the consumption of articles of food was as follows:—8,000lb. of bread, 16,000 rolls, 5cwt. biscuits, 1,000 fruit pies, 4cwt. fresh butter, 5,000 eggs, 4cwt. cheese, 2,500 lettuces, 1½ ton of potatoes, 600 quarts of shelled peas, 5 tons of ice, 600 quarts of ices, 780 gallons of tea, 130 gallons of coffee, 350 gallons of milk, 100 tongues, 169 hams, 5cwt. of salmon, 156lb. of eels, 20 turbot, 480 lobsters, 900 head of poultry, 6 tons of meat, 80 hhds. ale and stout, 760 gallons of claret cup, besides a large quantity of wines, spirits, liqueurs, and aerated waters. This great quantity of provision was distributed by an experienced staff, so that the little colony at Wimbledon have no drawbacks so far as catering is concerned.

THE STEAM SHIP "MALTA."

ATTENTION has recently been drawn to a screw steam ship, which was launched on the 29th of May last, from the ship-building yard of Messrs. Oswald and Co., Pallion, Sunderland. This has arisen not so much from her size—although that is considerable—as from the circumstance that she marks an era in ship-building upon the Wear. Previously, work had been sent past that river to the Clyde, by reason of the Scotch builders putting in the cost of the hull at a low figure, and laying it on upon the engines which they built within their own establishments. It is, therefore, desirable that the Wear builders should be induced to engine their steamers, and the port of Sunderland owes no small amount of thanks to Messrs. Oswald for the spirited example they have set their brother builders, in having both built and engined the "Malta"—the subject of the present notice—which is the first steamer so completed by a single firm on the Wear. The "Malta" was built for Messrs. Young, Ehlers and Co., of London, and the following are her principal dimensions:—Length over all 221ft.; breadth, 32ft. 2in.; depth, moulded, 17ft. 10in.; builders' measurement, 919 tons. Her engines are of the inverted direct-acting type, and on the surface condensing, high pressure, expansive principle, with improved expansive valves. The other dimensions and particulars are as follow:—Diameter of cylinders, 39in.; stroke, 33in.; nominal horse-power, 99; indicated horse-power, 659; consumption of coal per day, 9¼ tons; working pressure, 45lb.; steam superheated to 320deg.; vacuum, 26; revolutions per minute, 63; speed in knots per hour, 10½; draught, forward, 7ft. 6in.; draught. aft, 10ft.; classed 18 years at Liverpool. Yesterday week the "Malta" made her trial trip, and although we have no detail particulars of working to hand, yet we are able to state in general terms that she gave every satisfaction to her owners, and reflected great credit on her builders. The engines were objects of general attention. The compact manner in which the whole of that portion of the ship is arranged differs entirely from the ordinary run of north-country boats. The engineer may almost grasp his engine with one hand, and throw open the furnace doors with the other, while the ventilation proved to be very perfect, the engine-room being kept remarkably cool. The consumption of coal on a run of 200 miles is stated to be only 20cwt., which shows a very great economy. This is the first complete job that has been turned out from one establishment on the Wear, and having proved so satisfactory, will assuredly not be the last, but will, we trust, prove the means of opening up a good trade for the builders on the Wear generally, and Messrs. Oswald and Co. in particular.

IMPROVING THE NAVIGATION OF THE DANUBE.

THE formation of river deltas has always been a feature especially interesting to the student of physical geography and the geologist. Generally, these natural accumulations have to be sought for in the larger and more important rivers of the Continent and the New World, but it is probable that if the present system of discharging the London sewage into the Thames be continued, our geologists may have an opportunity of studying the formation of deltas at home. However interesting these fluvial deposits may be, viewed in a scientific and palæontological light, they constitute formidable obstacles to the navigation and commercial utility of the rivers in whose channels they are formed. For some years back the improvement of the Lower Danube has occupied the attention and the labours of a commission, the results of which now present tangible signs of progress. The principal objects to be accomplished by the commission were, firstly, the examination and amelioration of the different mouths, with a view to select the one most suitable for forming the main channel of navigation; secondly, the establishment of a regular system of water intercommunication; and, thirdly, the construction of the numerous and extensive works in connection therewith. That the contemplated project was upon a scale of considerable magnitude may be deduced from the fact that a whole year was employed in making a survey of the delta, and in obtaining the plans and soundings and levels necessary to enable a proper estimate to be formed of the *embouchure*, the best adapted for the intended purpose. At a short distance above its junction with the Black Sea, the Danube trifurcates, discharging its waters by a northern, southern, and intermediate channel, named respectively Kilia, Saint George, and Soulina. Of these three, the last was that generally used previous to the organization of the commission, and the first examination was directed towards ascertaining its capabilities. Some works of a temporary character were also constructed along its banks, pending the investigation in progress respecting the neighbouring channels. The northern branch, Kilia, has the advantage of possessing the greatest volume of water, but its many other disadvantages totally precluded any idea being entertained of adopting it for navigable purposes. Among these may be mentioned its subdivision into

no less than eight smaller channels, which, in addition, are continually shifting their course, and have, strictly speaking, no fixed mouths or outlets into the sea. To render these suitable for the navigation of vessels would have required the expenditure of an amount of money that would have been, in every sense, utterly unjustifiable. Moreover, supposing, for the moment, that other circumstances were favourable to the selection of this branch, its geographical position so much to the north would render it extremely inconvenient to vessels trading to the Bosphorus, as it would seriously lengthen their voyage.

The majority of the members of the commission were of opinion that it was both possible and necessary to improve the St. George's branch, the channel of which is wider and deeper than that of Soulina, without at the same time attaining to the proportions possessed by that of the northern outlet, Kilia. While nearly unanimous in finally reporting upon the feasibility of improving the southern branch, there was a good deal of discussion respecting the necessary works proposed in conjunction with the undertaking. This question was ultimately referred to the proper authority upon such matters, namely, the engineers, who advised the cutting of a canal having flood gates opening seawards. There were two objections to the execution of this scheme. One was that the accommodation would be totally inadequate to the exigencies of the navigation, and the other that the cost would reach the sum of £300,000. This latter impediment was fatal to the undertaking, and the further inquiry into the merits of this particular channel was postponed *sine die*. Having disposed of the claims of two of the branches under consideration, it only remained for the commission to concentrate its efforts upon the remaining one of Soulina, where, as already stated, provisionary works had been constructed. The final decision of the commission was, therefore, in favour of vigorously pushing forward all works that might be necessary towards rendering this channel adapted for a more important and extensive system of navigation than had yet been developed on the Danube. In order to effect the principal object, namely, the deepening of the water, the preference was given to the excavation of parallel trenches, instead of to dredging, as more likely to ensure permanent results. The depth of water at the bar was increased in this manner from 9ft. to 18ft., and has since been maintained at that datum. It is expected that in four years the works will be completed, and a free and uninterrupted communication established between the fertile provinces of the Danube and the ships of European commerce. At present, a vessel of 400 tons burden can easily pass the bar of Soulina, whereas formerly one of 200 only effected the passage with the greatest difficulty. Another very important advantage is to be found in the reduction of the dues, which are diminished nearly to one-half of their former amount.

To the fertile provinces situated along the route of this splendid river Europe is indebted for a large portion of its cereals. They are essentially corn-bearing provinces, and, if necessary, could feed nearly the remainder of the Continent. Owing to the exertions of the commission, Soulina has become the safest port in the Black Sea, and a continually increasing number of vessels entering its waters bear testimony to its value. Seven years ago, scarcely 20,000 tons were loaded at this port; now more than 120,000 tons are annually stowed away. The construction of a port and the improvement of the channel leading to it, should be so effected as not merely to afford increased accommodation to shipping of all kinds, but also so as to reduce to a minimum the chance of accidents to the ships frequenting it. During the last six years the percentage of wrecks at Soulina has decreased from 0·80 per cent. to 0·25, and when the works are completed it is confidently anticipated that the percentage will be still further diminished. The extension of the commerce of the Black Sea has had a considerable influence upon the tariff prevailing between the Danube and foreign ports. For example, a reduction of 3s. per quarter has been made between Galatz and England, which is quite sufficient to make itself felt in the market prices of flour and corn. During last year a vessel of 1,500 tons sailed up the river, a fact that some years ago would have been regarded as next to impossible.

THE ROYAL INSTITUTION.

ON Friday, May 28, Mr. J. Norman Lockyer, F.R.S., gave a most interesting lecture on "Recent Discoveries in Solar Physics made by the Spectroscope." He said that on March 4, 1866, he first applied the spectroscope to his telescope to examine the spots on the sun, in order to see if such a course would clear up the dispute between English and French philosophers, as to whether the spots were caused by the down rush of a comparatively cool absorbing atmosphere, or whether they were holes in the photosphere, as supposed by the French. The result was that plenty of evidence of absorption was seen, but not the bright lines which would be visible in a spectrum thrown by radiating gases; hence the opinion of Dr. Balfour Stewart and others, that sun spots are due to absorption, was corroborated.

In the autumn of last year, Mr. Lockyer succeeded in seeing the red prominences round the sun, which prominences had hitherto been visible only during total eclipses, when the overpoweringly brilliant rays from the limb of the sun were cut off by the dark body of the moon. The Astronomer Royal, Mr. Huggins, F.R.S., and Mr. Stone, of Greenwich Observatory, had all previously made attempts to see the prominences without an eclipse, but unsuccessfully, because the intense light of the photosphere completely eclipsed the light from the flames. The light from incandescent solids and liquids gives in the spectroscope a continuous spectrum; hence, by using a great many prisms, the light from the limb of the sun may be infinitely diluted and weakened, but the same spectroscope will not dilute the light from the prominences to the same extent, because radiating gases give bright lines instead of a continuous spectrum. On this principle, Mr. Lockyer first saw the light from the prominences without an eclipse, the appearances presented to the eye by his instruments being the solar spectrum, with a few bright lines projecting here and there from its upper edge. In some cases, these bright lines above corresponded in position with some of the dark absorption lines in the ordinary spectrum below, whereby it was at once ascertained that the prominences consist principally of burning hydrogen gas. About the same time that Mr. Lockyer discovered in England this method of viewing the prominences, Dr. Janssen, of Paris, did the same in India. By this plan, the lines C and F of hydrogen are seen without difficulty, and so are two of the hydrogen lines in the violet. Another line of hydrogen can only be seen when the weather is very fine, and in the early observations it was thought to be missing altogether. The F line widens out as it approaches the limb of the sun, and the experiments of Dr. Frankland and Mr. Lockyer prove that this widening out is due to the pressure of the sun's atmosphere at different elevations, also that the said pressure, even at the surface of the photosphere, is very slight—considerably less, in fact, than the pressure of the atmosphere upon our earth. In the lecture, Mr. Lockyer gave no technical description of his spectroscope, nor did he state what the experiments were which gave Dr. Frankland and himself the stated results, nor has any such practical information yet been published. Very soon after the discovery of this method of viewing the prominences, Mr. Lockyer found out that there is a sea of fiery gas all over the sun, outside the photosphere, and that the prominences are merely gigantic eruptions of this fiery sea. This newly discovered sea of flaming gas is about 5,000 miles in thickness, and has received the name of the "chromosphere." When the chromosphere is examined during a sun storm, the spectroscope reveals that large quantities of magnesium and other vapours are upheaved into it from the photosphere below. Mr. Lockyer also pointed out that the shifting of the hydrogen lines from their normal position towards the violet or red end of the spectrum is a measure of the velocity of the motion of the flames themselves, to or from the observer. Mr. Lockyer, by means of his apparatus, can see the prominences themselves, as well as their spectra, and the following are his words on this point:—

Hearing from Mr. De La Rue, on February 27, that Mr. Huggins had succeeded in anticipating me by using absorbing media and a wide slit (the description forwarded to me is short and vague), it immediately struck me, as possibly it has struck Mr. Huggins, that the wide slit is quite sufficient without any absorptive media; and during the last few days I have been perfectly enchanted with the sight which my spectroscope has revealed to me. The solar and atmospheric spectra being hidden, and the image of the wide slit alone being visible, the telescope or slit is moved slowly, and the strange shadow forms flit past. Here one is reminded, by the fleecy, infinitely delicate cloud films, of an English hedgerow with luxuriant elms; here of a densely intertwined tropical forest, the intimately interwoven branches threading in all directions, the prominences generally expanding as they mount upwards, and changing slowly—indeed, almost imperceptibly. By this method the smallest details of the prominences and of the chromosphere itself are rendered perfectly visible and easy of observation. With regard to seeing the prominences, I find that, when the sky is free from haze, the views I obtain of them are so perfect that I have not thought it worth while to remount the oscillating slit. I am, however, collecting red and green and violet glass, of the required absorptions, to construct a rapidly revolving wheel, in which the per centages of light of each colour may be regulated. In this way I think it possible that we may in time be able to see the prominences as they really are seen in an eclipse, with the additional advantage that we shall be able to see the sun at the same time, and test the connection or otherwise between the prominences and the surface phenomena.

Although I find it generally best for sketching purposes to have the open slit in a radial direction, I have lately placed it at a tangent to the limb, in order to study the general outline of the chromosphere, which in a previous communication I stated to be pretty uniform, while M. Janssen has characterized it as "*a niveau fort inegal et tourmenté*." My opinion is now that perhaps the mean of these two descriptions is, as usual, nearer the truth, unless the surface changes its character to a large extent from time to time. I find, too, that in different parts the outline varies: here it is undulating and billowy; there it is ragged to a degree, flames, as it were, darting out of the general surface, and forming a ragged, fleecy, interwoven outline, which in places is nearly even for some distance, and, like the billowy surface, becomes excessively uneven in the neighbourhood of a prominence. According to my present limited experience of these exquisitely beautiful solar appendages, it is generally possible to see the whole of their structure; but sometimes they are of such dimensions along the line of sight that they appear to be much denser than usual; and as there is no longer under these circumstances any background to the central portion, only the details of the margins can be observed, in addition to the varying brightnesses. Moreover, it does not at all follow that the largest prominences are those in which the intensest action, or the most rapid change, is going on,—the action as visible to us being generally confined to the regions just in, or above, the chromosphere, the changes arising from violent uprush or rapid dissipation, the uprush and dissipation representing the birth and death of a prominence. As a rule, the attachment to the chromosphere is narrow and is not often single; higher up, the stems, so to speak, intertwine, and the prominence expands and soars upward until it is lost in delicate filaments, which are carried away in floating masses.

Since last October, up to the time of trying the method of using the open slit, I had obtained evidence of considerable changes in the prominences

from day to day. With the open slit it is at once evident that changes on the small scale are continually going on; it was only on the 14th inst. that I observed any change at all comparable in magnitude and rapidity to those already observed by M. Janssen. About 9hrs. 45min. on that day, with a tangential slit I observed a fine dense prominence near the sun's equator, on the eastern limb. I tried to sketch it with the slit in this direction; but its border was so full of detail, and the atmospheric conditions were so unfavourable, that I gave up the attempt in despair. I turned the instrument round 90deg. and narrowed the slit, and my attention was at once taken by the F line; a single look at it taught me that an injection into the chromosphere and intense action were taking place. At 10hrs. 50min., when the action was slackening, I opened the slit; I saw at once that the dense appearance had all disappeared, and cloud-like filaments had taken its place. The first sketch, embracing an irregular prominence with a long perfectly straight one, which I call A, was finished at 11hrs. 5min., the height of the prominence being 1min. 5sec., or about 27,000 miles. I left the observatory for a few minutes, and on returning, at 11hrs. 15min., I was astonished to find that part of the prominence A had entirely disappeared; not even the slightest rack appeared in its place; whether it was entirely dissipated, or whether parts of it had been wafted towards the other part, I do not know, although I think the latter explanation the more probable one, as the other part had increased.

Mr. Lockyer threw a fine picture of this storm in the sun upon the screen.

NOTES ON RECENT SCIENTIFIC DISCOVERIES, AND THEIR PRACTICAL APPLICATIONS.

THE PASCAL-NEWTON FORGERIES—RENOVATING OLD FILES AND RASPS—ECONOMY OF USING LIME GROUND TO POWDER—THE DENSITY OF HYDROGENIUM.

WE alluded in our number for June 4 to a process for copying old writing, which was said to enable us to decide approximately on the age of a written document, and mentioned the willingness of M. Chasles to submit some of the letters said to have been written by Pascal to this test. The operation was confided to M. Balard, who has found that dilute hydrochloric acid has no effect upon the ink, from which circumstance he is disposed to infer the antiquity and genuineness of the documents. It is hardly necessary to say that we regard the test as altogether inconclusive. The clumsiest forger would never think of imitating ancient writing with modern ink; and although, as we said, inks containing iron have been known in Europe from a very early time there can be no doubt that the composition most commonly employed was prepared with some form of carbonaceous matter as its colouring base. It resembled, in fact, Indian ink. On such a preparation, hydrochloric acid would have no effect. If it were worth the trouble, an experiment might be made on some of Chatterton's forgeries, which are still, we believe, in existence. With regard to this pretended Pascal-Newton correspondence, invented to deprive our great philosopher of the honour of his chief discoveries, we need only say that at the last meeting of the Academy of Sciences, M. Le Verrier conclusively proved its unauthenticity from the internal evidence of the letters themselves. The sources from which the matter of many of them was taken was clearly shown, and the exposure of this most audacious forgery of modern times was complete.

We make an addition to the notice we gave a few weeks back of a process for renovating worn down files and rasps. The tools, when immersed in the mixture of nitric and sulphuric acids and water, are connected with the positive pole of a battery, and the negative pole is formed of a spiral of copper riband surrounding the tool. Ten or twenty minutes' action with a dozen of Bunsen's cells suffice, in general, it seems to eat out the cuttings so as to restore the file or rasp to a useful condition. Without having much faith in the process, we mention it because we are told that it is employed with success in some large workshops in Paris, and that one railway company renovates by its means "some thousands of files every week."

The economy of using lime ground to powder instead of slaking it in lumps is the subject of an able report by a French engineer, who estimates the loss in lumps at 25 per cent. Besides this saving of material, it is clear that the mortar will be more easily made, and, being smoother, will be spread with greater facility, thus saving time. It is said further that the mortar sets quicker and more solid. Lime in powder is also transported more easily than in lump, and we read that the works on the Suez Canal have been executed with the powder shipped from Marseilles. The assertion that lime keeps better in powder than lump is, we think, open to doubt. Still, we are quite willing to believe that many advantages may be derived from the use of the material in fine powder.

We may add a few words in extension of our notice last week of Mr. Graham's new researches on hydrogenium. When hydrogen is occluded by palladium wire, the wire elongates. When the hydrogen is expelled by the application of heat the wire retracts again, and to less than its original length. Thus Mr. Graham is led to suppose that when the hydrogen enters the palladium molecules retract, and since the permanent retraction is just about equal to the temporary elongation, the hydrogen would appear to occupy double space it might be supposed to occupy if the elongation only be considered. It is for this reason that Mr. Graham now concludes that the density of hydrogenium must be assumed to be about half that he originally stated. A series of experiments made with alloys of palladium with other metals—platinum, gold, silver, and others—supports this opinion. When, for example, hydrogen is occluded by an alloy of palladium and platinum, no retraction follows the expulsion of the gas by heat, although the expansion is about twice as great as with pure palladium. It would seem, then, in this case, that the platinum sustains the palladium, that no retraction of the molecules of this metal takes place when the hydrogen enters, and thus there is no permanent retraction when the gas is expelled. Corresponding results were obtained with alloys of palladium with gold and silver, which occlude smaller volumes of the gas than the alloy previously mentioned. All the results, however, point to the conclusion that "0·73 may be accepted provisionally as the approximate density of hydrogenium."

PARLIAMENTARY NOTES.

THE sanitary condition of the School of Musketry at Hythe appears open to improvement, if we may judge from Lord Kinnaird's remarks, when moving for a report upon the subject in the House of Lords on Monday evening. His Lordship wished also to know the number of officers reported sick between March 1 and April 30, 1869, and the cost of maintaining the establishment of the School of Musketry there for one year. In moving for this return, he wished it to be distinctly understood that he did not in the least degree wish to disparage the great importance of this school for the British army. Considering the marked improvements that were being made in the small arms, it was absolutely necessary that the British soldier should thoroughly understand their use, and that the officers should know how best to turn them to account. In the spring, his attention was called to the outbreak of fever at Hythe, and he accordingly paid a visit to that place. He found that the drainage of the town flowed into an open canal belonging to the Government, which was originally constructed for the purposes of defence, which was covered with decayed vegetable matter. The canal runs at the foot of the barracks, and under the barracks was a ditch partly open and partly covered. There was refuse matter 18in. deep in the open parts, and he would leave their lordships to imagine what state the covered parts were in. He was informed that in hot weather, with a south-west wind, the smell was very unpleasant. It was only right to say that the medical officer did not attribute the outbreak of fever to bad drainage, but to the officers throwing off their winter clothing owing to the hot weather suddenly setting in; but it was singular that thirty or forty men should have been attacked in a similar manner to the officers by fever which very much resembled the jungle fever of India. To some extent, the medical officers stated the place was unhealthy, and that the men from India, with weakened constitutions, could not stand the severity of the two months' drill at Hythe, and it was necessary, he (Lord Kinnaird) understood, to cram three months' drill into two in order to accommodate a proper number of men within the year. The lecture room was in a garret close to the slates, in which 150 men were seated at a time, and these had to succeed each other so rapidly in classes that it was most unhealthy for the men. He considered that Fleetwood contrasted most favourably with Hythe, and he suggested whether it would not be desirable to reopen it as a school of musketry.

In the House of Commons, on the same evening, Mr. Alderman Lawrence asked the Secretary of State for the Home Department if the attention of the Government had been directed to the late accident in the neighbourhood of Carnarvon, caused by the explosion of nitro-glycerine; and, if so, whether they would take means to prevent so dangerous and explosive an article as nitro-glycerine, which was almost exclusively used for mining purposes, being either stored within or transported through the metropolis.

Mr. Bruce said he was not at all surprised at the question of his hon. friend, because he could not but admit that his anxiety is very well founded. Legislation in reference to the transport of nitro-glycerine already existed, but it was not effectual in the case of the explosion at Carnarvon, for, so far as he was aware, no breach of the regulations took place. If it had occurred in a populous district, or a large town, a large sacrifice of human life might have taken place, and immediately after he received intelligence of the sad misfortune he directed an inquiry to be made, by a competent authority, whether it is possible to deprive nitro-glycerine, during transport, of its explosive qualities. To that inquiry he had not yet received a definite answer. If there were any means of making it non-explosive he thought it was absolutely necessary that they should be enforced on all persons who convey it. If there were no such means, he thought its conveyance ought to be absolutely prohibited. There *are* means of depriving this deadly material of its power during transport, and again restoring it when required for use, by admixture with methylated spirit. But far better than this would be the employment of dynamite, a mixture of nitro-glycerine and sand, and which cannot be exploded except by a percussion fuse. There is also the safety gun cotton, as prepared by Messrs. Prentice under Professor Abel's pulping process, and which only burns quietly out when ignited, even in quantity, in an unconfined condition. But when fired in a close chamber, such as a gun barrel or blast hole, its full energy is developed.

Later on in the evening, and in a committee of the whole House, Sir J. Hay obtained leave to bring in a bill to prohibit the importation and regulate the conveyance of nitro-glycerine, and the bill was afterwards introduced and read a first time.

The recent boiler explosions appears to have put nervous members on the *qui vive* as to the steam power employed in the Houses of Parliament, for Mr. H. B. Sheridan gave notice that on Tuesday he would ask the President of the Board of Trade whether he had yet received a full account of the number of persons killed and injured by the terrible explosion at Bingley, which occurred about three weeks ago, and whether it was true that twenty persons were killed and nearly forty persons seriously injured by that explosion; and whether he could give any information as to the loss of life and property and the injury to individuals which had resulted from the boiler explosions which had since occurred, viz., at Wheal Bassett, near Redruth; at Lord Durham's Sherborne House Colliery, at the Abergwawr Colliery, at Calderbank, belonging to the Monkland Iron and Steel Company; and the one on Monday last, at Nuneaton, on property belonging to Mr. Newdegate, M.P. The hon. gentleman also gave notice that he would ask the First Commissioner of Works whether it was true that a large number of boilers were under the Houses of Parliament, and what number of boilers are under the floor of the House of Commons, and what is the size and capacity of such boilers and the pressure per square inch, and whether the boilers under the floor of the House are periodically tested and examined, and when they were last thoroughly inspected and examined, and by whom?

On Tuesday, Mr. Sheridan put the question, so far as it related to the explosions in question. He, however, omitted all notice of the boilers under the Houses of Parliament, having, doubtless, been satisfied in the meantime that he had nothing to apprehend from a blow-up in that quarter, at any rate. Mr. Lefevre's reply to the question which was put was to the effect that neither he nor the Home Office had received any information on the subject; consequently, he was unable either to deny or confirm the statements to be inferred from the questions.

THE INSTITUTION OF CIVIL ENGINEERS.

THE council of the Institution of Civil Engineers have awarded the following premiums:— 1. A Telford medal, and a Telford premium, in books (to consist of a complete set of the publications of the Institution), to M. Jules Gaudard, C.E., Lausanne, for his paper "On the Present State of Knowledge of the Strength and Resistance of Materials." 2. A Telford medal, and a Telford premium, in books, to William Shelford, M. Inst. C.E., for his paper "On the Outfall of the River Humber." *3. A Watt medal, and a Telford premium, in books, to Zerah Colburn, M. Inst. C.E., for his paper "On American Locomotives and Rolling Stock." 4. A Telford medal, and a Telford premium, in books, to Thomas Nesham Kirkham, M. Inst. C.E., for his paper "Experiments on the Standards of Comparison employed for Testing the Illuminating Power of Coal Gas." 5. A Telford medal, and a Telford premium, in books, to John Ellacott, M. Inst. C.E., for his "Description of the Low Water Basin at Birkenhead." 6. A Telford medal, and a Telford premium, in books, to Professor David Thomas Anstead, F.R.S., for his paper "On the Lagoons and Marshes of certain parts of the Shores of the Mediterranean." 7. A Telford premium, in books, to William Henry Wheeler, M. Inst. C.E., for his "Description of the River Witham and its Estuary, and of the various Works carried out in connection therewith, for the Drainage of the Fens and the improvement of the Navigation." 8. A Telford premium, in books, to James Robert Mosse, M. Inst. C.E., for his paper on "On the Mauritius Railway, Midland line." 9. A Telford premium, in books, to Imrie Bell, M. Inst. C.E., for his paper "On Sinking Wells for the Foundations of the Piers of the Jumna Bridge, Delhi Railway." 10. A Telford premium, in books, to John Milroy, Assoc. Inst. C.E., for his "Description of Apparatus for Excavating the Interior of, and for Sinking, Iron Cylinders." 11. A Telford premium, in books, to Samuel Parker Bidder, jun., Assoc. Inst. C.E., for his paper "On Machines employed in Working and Breaking Down Coal, so as to avoid the use of Gunpowder." 12. A Telford premium, in books, to Charles John Chubb, for his paper "On Coal-getting Machinery as a substitute for the use of Gunpowder." 13. The Manby premium, in books, to David Marr Henderson, Assoc. Inst. C.E., for his paper "On Lighthouse Apparatus and Lanterns."

The Council have likewise awarded the following prizes to students of the Institution:—A Miller prize to Edward Bazalgette, Stud. Inst. C.E., for his paper "On the Use of Concrete in Building Operations." 2. A Miller prize to Frederick Harry Mort, Stud. Inst. C.E., for his paper "An Inquiry into the Nature and Causes of some Discrepancies between Theory and Practice." 3. A Miller prize to Tristie James Ellis, Stud. Inst. C.E., for his paper "On the Artistic Design of Bridges." 4. A Miller prize to Thomas Robert Gainsford, Stud. Inst. C.E., for his paper "On the Construction of a Railway Tunnel or Covered Way at Bradford, Yorkshire, among Abandoned Coal and Ironstone Workings." 5. A Miller prize to Charles Henry Grey Jenkinson, Stud. Inst. C.E., for his paper "On Wrought-iron Girder Bridges." 6. A Miller prize to George Henry Roberts, Stud. Inst. C.E., for his paper "On Reservoir Embankments."

CASTING PLOUGH HEADS, &c.

IN casting plough heads in steel by the process at present in use, considerable expense is incurred in preparing suitable moulds of sand or loam, which require to be carefully dried, and then serve only for the production of a single casting. With the view of superseding this method, Messrs. David Greig and John Fernie, of Leeds, have patented an invention, which consists in casting the plough heads in a metal mould, by which means much labour is saved in the production, as one mould will serve for the casting of an indefinite number of heads. The metal moulds or chills are cast from models made in the ordinary way. They may be cast from moulds made in plaster, and the inventors prefer them made in steel. They are fixed with hinges to a frame, so that when the castings are made the parts of the chill swing open and the casting is quickly extracted. At the parts where the fluid steel first touches the chill a recess is made, into which loam is inserted to prevent the chill being cut away by the action of the steel. When possible, the steel is allowed to ascend into the chill from the bottom or sides instead of falling into it. The interior of the chills are coated with washes composed of clay ground, powdered blacklead, or they are smoked in the ordinary way.

The mould is constructed in some cases in such manner that when the metal contracts, portions of the mould, which, if they remained rigid, would pull or tear the casting, are allowed to yield to the contraction, and no strain is thrown on the casting while it is in the soft or plastic state. This is effected by placing in those parts of the mould subject to compression loam or sand, of sufficient thickness to resist the pressure of the fluid steel or metal, but of so open a nature and of such a form as to give way or crumble with a slight compression. The inventors also use a material having a thin face of loam to resist the metal, and a backing of a material which will melt or burn out when the heat from the melted metal penetrates through the thin face. By these means portions of the mould are allowed to contract. Another method proposed is to release those parts of the mould subject to compression by withdrawing wedge pieces immediately the metal is poured into the mould.

In casting toothed and other wheels in steel, metal moulds are also employed, and they are constructed with yielding or movable parts, as just described. In forming the moulds for casting pinions which have their teeth smaller at the root than they are at the pitch line, a number of small pieces of metal, corresponding to the spaces between the teeth are employed, and these are arranged in the interior of the mould; they are of such a form that they will be drawn in when the contraction of the metal takes place.

In casting crank axles in cast steel the moulds are of such an internal form that the proper twist, right or left hand, is given to the ingot, and when the metal has been poured into the mould the inventors force in, by screws or hydraulic power, blocks of metal through the sides of the mould into the throws of the cranks, at those parts where the casting has to be cut out when forming the crank pins. By this means they prevent the formation of unsoundness in the throws, which would otherwise happen from the metal remaining longer hot in those parts in consequence of their larger size. In making double-crank axles the portion of the mould between the webs or throws is allowed to contract by the means already described, so that no strain is thrown on the casting between the webs in consequence of contraction.

* Has previously received a Telford medal.

STEAM BOILER EXPLOSIONS.

OUR readers are aware a bill providing for the periodical inspection of steam boilers has been prepared and brought in Parliament during the present session by Mr. Henry B. Sheridan, Mr. Vickers, and Mr. Brady. The following is a copy of the bill:—

Whereas it is expedient that Her Majesty's subjects should be protected by a proper system of inspection and registration from accidents occasioned by the explosion of steam boilers:

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in the present Parliament assembled, and by the authority of the same, as follows:—

1. From and after the day of one thousand eight hundred and the Lords of the committee of Her Majesty's Privy Council appointed for trade and foreign plantations, hereafter called the Board of Trade, shall have power, and they are hereby required, immediately after the passing of this Act, and from time to time, to issue rules and orders by which a complete and effective system of registering, inspecting, testing, and ascertaining the safety and security of steam boilers in the United Kingdom of Great Britain and Ireland shall be established and carried into effect, and such rules and orders shall have the same legal authority and effect as if they were incorporated in and formed part of this Act: Provided always, that all such rules and orders shall be placed before Parliament within six months after they have been issued by the Board of Trade.

2. A registrar and inspector-general of steam boilers for the United Kingdom of Great Britain and Ireland shall be appointed by the Board of Trade immediately after the passing of the Act, and the duties and powers of such registrar and inspector general shall be defined and governed by the said rules and orders to be issued by the Board of Trade. Such salary as Her Majesty's Treasury shall deem an adequate and proper remuneration for the services to be performed by the said registrar and inspector-general shall also be paid to him under and by virtue of this Act out of such funds as Parliament shall provide for that purpose.

3. The registrar and inspector-general of steam boilers appointed under and by virtue of the last preceding section shall, subject to the said rules and orders of the Board of Trade, have power to appoint deputy registrars and sub-inspectors, with such salaries and allowances as he shall deem necessary and proper, the said salaries and allowances to be paid out of such funds as Parliament shall provide for that purpose; and, to give effect to the authority, powers, and duties to be exercised and performed by such deputy registrars and sub-inspectors, the said registrar and inspector-general, having regard, nevertheless, to the said rules and orders of the Board of Trade, shall limit and confine the authority, powers, and duties so to be exercised by the said deputy registrars and sub-inspectors to the counties, cities, towns, and districts particularly indicated and set forth in written instructions to be issued to them by the said registrar and inspector-general.

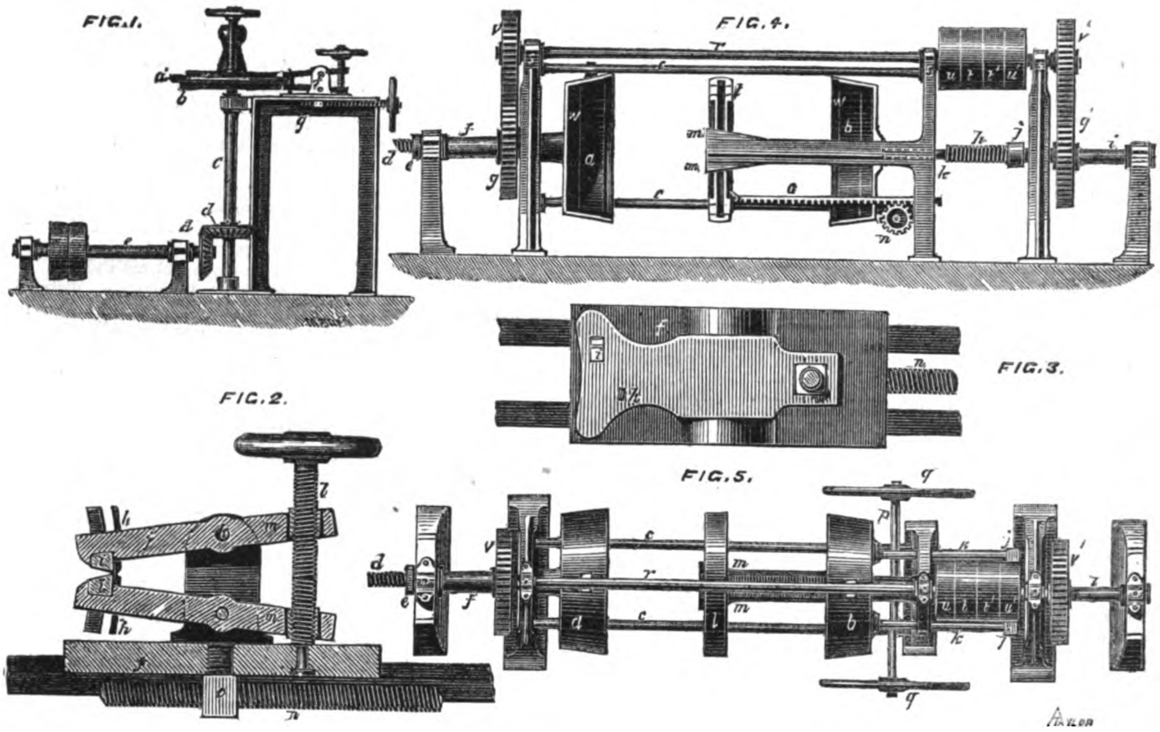
COAL IN PRUSSIA.

SOME facts relating to the consumption of coal, compiled from official sources, are given in the "North German Correspondent." It appears that the consumption of English coals in Berlin and the Prussian inland provinces has for some years past shown a gradual diminution, owing to the increasing use of Silesian and Saxon (Zwickau) coals. Notwithstanding this, the whole importation of English coals into the Zollverein from 1857 to 1867 shows an augmentation of 4,418,300 centners, or 22 per cent., an increase entirely owing to the very large consumption of these coals in the maritime provinces of Prussia, which can procure them cheaper by sea from England than from the interior, or from Saxony by land carriage. In the ports of the North German Confederation English coals are yearly becoming more important as an article of commerce. In 1867 Lübeck imported 22,299 tons; Memel, 35,319; and Neufahrwasser, 16,840; or, together, 74,458 tons of English coals; and there is not a single Baltic port in which their purchase and sale do not give rise to large transactions every year. The "Staats-Anzeiger" collates the quantities of coals raised in England and Prussia respectively during the years 1867 and 1868. In Great Britain, in the former year, 3,195 coalpits, with 333,116 workmen, produced 105,078,000 tons, or 2,133,083,000 zollcentners. In 1868 the production had fallen to 104½ millions of tons, or 2,121 millions zollcentners, while the number of pits had risen to 3,291, and that of the miners to 346,820. In Prussia, during the year 1867, 426 pits, with 102,773 workmen, produced 420,571,116 centners of coals, and in 1868, with 106,348 men, they yielded 454,486,660 centners. While the coal production of Great Britain in the year 1854 was ten times greater than that of Prussia, being 64,661,000 tons, or 1,312,618,300 centners, against 136,225,096 centners, in 1867 it was only five times as great, and in 1868 only 4·6 times. Leaving out of account the recent territorial acquisitions of Prussia, we find the production of coals in the old provinces amounted in 1868 to 4·7 of that of Great Britain. While the amount of coals raised in the latter country from 1854 to 1868 increased by 40 millions of tons (812 millions of centners), or 62 per cent., it rose in the old Prussian provinces to no less than 310,379,729 centners, or 227·8 per cent. The average yield of a coalpit in Great Britain in 1867 was 667,000 centners, and 644,000 centners in 1868; in Prussia it was 987,000 centners in 1867, and 1,067,000 centners in 1868. On the other hand, the average quantity raised by each miner in the two years was 6,398 and 6,116 centners in Great Britain, and 4,092 and 4,273 centners, or 48 per cent. less, in Prussia. The proportion of accidental deaths of miners in 1867 was 1 in 280, and for every 1,792,490 centners of coals produced in Great Britain; in Prussia one man in 352·5, and for every 1,440,157 centners raised. Of the entire accidents in British mines in 1867, 24·3 per cent. were caused by explosions, against 13·31 in Prussian pits; 37·73 per cent., against 36·13 in Prussia, by earth-slips; 17·73 per cent., against 25·26 in Prussia, by other accidents underground; 7·40 per cent., against 3·7 by accidents above ground; and 13·11 per cent., against 22·18, by accidents in the shafts.

FIVE beautiful pearls, found at the newly-discovered fisheries in Western Austrlia, were brought to this country by the last mail.

CASK-MAKING MACHINERY.

BY MR. JOHN REID.



REID'S CASK-MAKING MACHINERY.

IN our last issue we described and illustrated some portions of the cask-making machinery invented by Mr. John Reid, of Glasgow, particulars of which we took from the "Brewers' Journal." We now conclude our notice with a description of his machinery for forming the sides of barrels, and of his trussing machine, which are illustrated in the accompanying engravings. Fig. 1 is a side elevation of the first-named machine; the bars *a*, of which the ends are constructed, are placed on the revolving table *b*, which is fixed to the vertical shaft *c*, actuated by the bevel wheels *d*, from the shaft *e*. The cutters by which the ends are cut to the circular form, and to the required bevel around the edge, are carried in a saddle *f*, mounted on a slide on the table *g*. Fig. 2 is a horizontal section of the saddle, showing the cutters, and fig. 3 is a plan of the same, drawn to an enlarged scale. *h h* are the cutters by which the ends are cut to the circular form, each cutter cutting half through the bars *a*. The edges are cut at the same time to the required bevel by the cutters *i i*. The holders *j j* are centred by the axes *k k*, and are gradually brought together by the right and left-handed screw *l*, working in swivelling nuts *m*. The saddle is slid backwards and forwards by the screw *n*, working in the nut *o*, so as to suit any required diameter of end.

Fig. 4 is a sectional elevation of a trussing machine, upon Mr. Reid's improved principle, fig. 5 being a plan of the apparatus. It consists of two circular frames or cones *a b*, placed one at each end of the machine, and supported on the guide bars *c*. During trussing operations, the cones travel towards and from the centre of the machine, the cone *a* being actuated by the screw *d*, which passes through and works in a nut *e*, at the end of the hollow shaft *f*, on which the spur wheel *g* is keyed. The cone *b* is actuated by the screw *h*, which is formed on the end of the shaft *i*, and works in a crosshead *j*, which is attached to the cone by the rod *k*. Midway between the cones is placed an expanding and contracting disc *l*, which is slid backwards and forwards upon the inclined planes *m* by the pinion *n* gearing into the toothed rack *o*. The pinion *n* is keyed on the cross shaft *p*, which is rotated by the handwheels *q*. A shaft *r* is supported upon the standards *s*, and is fitted with two fast pulleys *t* and *t* ¹, one being operated by an open belt for drawing the machine in one direction, and the other by a cross belt for reversing it. Two loose pulleys *u* and *u* ¹ are provided for stopping the machine. The screws *d h* which actuate the trussing cones *a b* are operated by the pinions *v* and *v* ¹ gearing into the wheels *g* and *g* ¹.

The *modus operandi* of the trussing machine is as follows:—The cones are drawn apart to a distance a little less than the length of the staves to be used, and the disc *l* is expanded by being pushed towards the centre of the machine, until the diameter of the disc is equal to the greatest internal diameter of the barrel. The binding hoops are placed in the recesses *w*, which are formed in the trussing cones. The staves are now built round the expanded disc, and the bottom or one end may be placed in at one end of the staves which rest in the cone *a*. The cones are then moved simultaneously towards the centre by the actuating mechanism, until the ends of the barrel have nearly arrived at the bottom of the cones. The machine is then thrown out of gear until the disc is drawn back and contracted by means of the rack and pinion. The machine is then reversed, and the cones are moved outwards, leaving the hoops which were placed in their recesses on the barrel, which is now removed from the machine. The disc is afterwards pushed forwards and expanded to the proper diameter for building up the next barrel.

THE EAST RIVER BRIDGE, U.S.A.

THE plan of the East River bridge, as proposed by Mr. Roebling, has met with the approval of the Board of U.S. Engineers, appointed to examine it, and of the Government, and has been fully adopted by the Board of Consulting Engineers, consisting of Horatio Allen, William J. McAlpine, J. J. Serrell, Benjamin H. Lathrop, James P. Kirkwood, and J. Dutton Steele, who have made to the directors of the Bridge Company their final report, of which the following is the substance:—The plans, including foundations, towers, and superstructure have been laid before the Board by Mr. Roebling at various times between February 16 and April 26, and from him they have received the fullest information touching all the details. Having completed the examination of the plans and the investigation of the combinations and proportions proposed, the Board deemed it an appropriate part of their duty to examine the structures of the same general character erected by Mr. Roebling across the Monongahela and Allegheny, at Pittsburgh, in 1846 and 1860; across the Niagara Falls in 1850, and across the Ohio, at Cincinnati, in 1860. They have thus had an opportunity of learning the successive steps in bridge building, which, beginning with a span of 822 in 1854, and one of 1,057ft. in 1867, all standing this day—a practical demonstration of the soundness of the principles and proportions on which these structures have been erected, and rendering unnecessary, at least for spans of 1,000ft., any other demonstration, and affording the best source of information as to the practicability of taking another step in a span of 1,600ft. The bridge proposed by Mr. Roebling, a steel wire cable suspension bridge, 1,600ft. between the towers, 135ft. above the water, will be, in the opinion of the board, a durable structure of a strength sufficient to withstand six times the strain to which it can under any circumstances be subjected, that it will bear the action of the greatest storm of which we have any knowledge, and that the method of joining the parts cannot be surpassed for simplicity and security in the result.

STEAM FIRE ENGINE FOR THE GREAT WESTERN RAILWAY.

CONSIDERABLE interest was excited at Swindon on Saturday last, the 10th inst., by the trial of a new steam fire engine, selected by Mr. Armstrong, after a careful investigation, for the protection of the railway works. The engine is one of Shand, Mason, and Co.'s medium size, so well known in London, the provinces, and foreign countries; but the principal novelty was in the application of their new patent inclined water tube boiler. The experiments were conducted under the superintendence of Mr. Armstrong and Mr. Dean, in the presence of a number of gentlemen connected with the Swindon Works, the following being Mr. Dean's attested statement of the time occupied in getting up steam:—Fire lighted at 40sec. after 1 o'clock p.m., cold water being used, with oak shavings and broken wood from the workshops as fuel; 5lb. steam pressure was obtained in 3min. 50sec., 10lb. in 4min. 28sec., 20lb. in 5min. 12sec. (when a jet of steam was admitted into the chimney), 30lb. in 5min. 55sec., 60lb. in 6min. 33sec., and 100lb. in 7min. 5sec. At this pressure, which was easily maintained throughout the trial, the engine was started. Various jets, up to 1⅜in. diameter, were used, the water being projected upwards of 200ft. The steady working of the engine, and the remarkable steaming properties of the boiler, were admired by all present, although at a previous workshop trial 100lb. steam pressure was obtained in 6min. 40sec. The Metropolitan Fire Brigade are now under the necessity of using gas at a very great cost to keep hot water in the boilers of their steam fire engines, in order to reduce the time for raising steam—an expense which would be entirely saved by the use of the new boiler.

THE CLOCK OF BEAUVAIS CATHEDRAL.

FROM the remotest periods man has felt his way towards measuring that impalpable agent, ceaselessly progressing, never resting time. He has measured it by torches of pitch which should burn regularly. He has invented the hour-glass and the clepsydra, where grains of sand or drops of water falling from one vessel into another indicated its passage. He has invented the sun dial. What

has he not imagined, from the time when, having discovered the mariner's compass in 1303, he perceived and applied the principle of gravity as it exists in the pendulum. This was the great advance, the chief step forward which opened the door of discovery to the learned to the mysteries of astronomy. By the exact measurement of time some of the greatest natural problems had been solved. But that man who would ask of horology nothing more than the indication of the time for his repasts and his repose, is profoundly indifferent to its aim and object. However, an inventive genius constructed the clock of the cathedral of Strasbourg which indicates a mass of things unrecorded in the almanacs of the period. This was regarded with the veneration with which a saint was invested, speaking a dead language unknown to the multitude. Since that time, mechanical invention has become so general that the clock of Alsace has ceased to be a mystery to all but the learned, the possession of a time-keeper being now common to most of us.

Something novel was further desired, and this novelty a clock maker of Beauvais has given us. But this is a little history. Do you know the cathedral of Beauvais? The span of its roof leaves a space of full 50 yards. This is unfinished, and for 200 years nothing but an ugly wall saluted the eye as a blemish on this colossal monument. To cover this defect the chief inhabitants (to the number of 10) met and clubbed together to place there a monumental clock. To accomplish this purpose, money and an horologist were required. The clock maker was at hand, a fellow townsman had just finished a splendid work for Besancon. A sum of £1,600 having been collected, the work was begun. Twenty workmen, 10 of whom are clock-makers, have been at work for four years. The accomplishment of this great work leaves far behind all previous attempts in this direction. The result is a work composed of 14 different movements consisting of 90,000 pieces, weighing over 35,000lb. and costing £5,600, or £4,000 more than the sum first collected, but against this excess is to be reckoned a *chef d'œuvre* which future ages may well be debited with. The body of the clock is 36ft. high, it is made of sculptured oak in columns, and measures 16ft. in breadth by nearly nine in depth; the whole is finished in the byzantine style of decoration. The figure of the Supreme Being from the summit of the clock, at every hour, by a solemn gesture, calls attention to the saints who are at their alcoves yielding attention to the sounds which accompany the crowing of a fine cock.

The main dial, there are 50 in all, is occupied by the figure of the Saviour enamelled on copper, the largest work in enamel existing; it cost £130. Above their divine Master the 12 apostles, also in enamel, figure in a circle artistically expressive of devotion. Two hands of steel covered by platinum move over this dial through 24 divisions; it is pierced, as are all the others, and shows the pendulum, weighing nearly 1cwt., which renews its impulse from a steel ball weighing a gramme, or about the 32nd part of an ounce. This impulse is thoroughly the product of mechanical inventiveness, and is, as it were, an allegory exhibiting the submission of brute force to intelligent direction. This movement impels the 14 others, and is wound up weekly, being driven by weights in the usual way. The other dials indicate:—The days of the week. The movements of the planetary bodies. Sun rise. Sun set. The seasons. The signs of the Zodiac. The duration of daylight. The duration of night. The equation of time. The dates. The saints' days. The months. The phases of the moon. The age of the moon. The time at the principal cities of the world. The solstices. The movable feasts. The age of the world. The year of the century. The bissextile years. The longitudes. The number of the century. This portion of the machinery exhibits no indication more than once in 100 years, but nothing more is required than to wind the machine every eighth day. Other dials show further:—The tides. The eclipses for all the world, both total and partial. At the hour when the sun or moon is eclipsed in the heavens, to the minute even, the sun or moon suffers obscuration on the clock. To form a correct appreciation of the enormous work and calculation in this great machine, unequalled anywhere, which has its separate movement from that which shows seconds of time to those which indicate events occurring not oftener than once in 100 years, it must be remembered that three centuries out of four the last year leaps its bissextile. In these years the clock has to leap from February 29, and goes from the 28th to the 1st of March. Here is a movement occurring only in 400 years. What is left but to admire the inventive genius which has combined in one harmonious whole and subjected to a uniform direction 90,000 separate pieces, all uniting to measure and indicate the footsteps of time, showing the positions of the smaller and the greater heavenly bodies in both worlds; even those we see nothing of, which exist in the other hemisphere, and of which this clock faithfully records the rising and setting. The inhabitants of Beauvais possess a wonder of the world, and we are indebted to them for showing it at the Exhibition of Paris, where its modest inventor explained its operations, and who by a remarkable coincidence bears a name strictly in harmony with his devotion to exact science. His name is Verite. —Translated from the "Petit Journal," of Paris, by S. J.

Note:—Mr. Steckelburger, of Strasbourg, jealous for the honour of his native town, protests as follows against the assumption that the Beauvais clock is unequalled:—Mr. Mauremont says that the astronomical clock of Strasbourg has no longer any secrets for anybody. For a very good reason, indeed! He is speaking of that which was constructed in 1574 by Isaac Haberecht. How could this poor machine have any secrets for any one, since it was taken down 30 years ago, and the various parts placed in the religious establishment of Notre Dame, where it may still be seen. But this is not the clock we have to do with; the present clock dates from 1842: it is that constructed by Mr. Schwilgue.

I could not suppress a smile at the catalogue of indications said to be shown by the Beauvais clock, for our cathedral clock shows all these and some besides. It shows all the wonderful things in the almanacs, and all the astronomical calculations possible and perpetual. It contains an ecclesiastical computator with all its indications; the golden number, the epacts, dominical letter, solar cycle, &c.; a perpetual calendar with the movable feasts, a planetarium on the Gopernican system, showing all the mean equinoctial revolutions of every planet visible to the naked eye; the phases of the moon; the eclipses; apparent and and sidereal time; a celestial sphere showing the precession of the equinoxes, the solar and lunar equations for the reduction of the mean motion of the sun and moon to true time and place. What else I hardly know. The Beauvais clock makes a change in every fourth century; a great merit! The precise indication is exhibited here, but ask an astronomer what is meant by the precession of the equinoxes. He will tell you it is a movement in the stars describing a complete revolution round the earth in the space of about 25,000 to 26,000 years. Well, Sir, in the Strasbourg clock is a sphere following exactly this motion, and whose rotation is of that kind as to ensure one revolution in 25,920 years. The thing can be measured and indicated; it is unnecessary to await its accomplishment: it would be too remote. If your correspondent will but pay a visit to Strasbourg, I shall be pleased to conduct him to this famous work of our regretted M. Schwilgue.—"Horological Journal."

MANURE FOR HOP GROUNDS.

THE economical habits of our neighbours of France offer us many useful lessons, especially in those industries in which scientific questions enter largely; and, when properly understood there are few industries indeed which do not come under this head. The question of the proper kind of manure for hop plantations is one that has been largely discussed; and we see by the "Brewers' Journal" that M. Gueymard, of Grenoble, has done good service in showing what kind and what quantity of manure the hop plant itself supplies towards its own reproduction. Having analysed chemically the composition of the stalks, leaves, and cones or flowers, he finds that they contain the following percentages of fertilizing substances:—

	Stalks.	Leaves.	Flowers.
Soluble salts of potash .	1·41	2·02	2·92
Carbonate of lime . .	2·58	8·00	2·53
Magnesia . . .	0·31	1·70	0·60
Phosphoric acid . .	0·80	1·26	1·26
Oxide of iron and alumina	0·38	1·70	0·70

If, then, the leaves as well as the stalks of the bine, cut up in a chaff-cutting machine, as recommended by M. Gueymard, be left on the ground as manure, nothing more requires to be added but the fertilizing principles taken away by the flowers, which average about one ton per hectare (2½ acres), and, consequently, contain about 44lb. of potash and 15lb. of phosphoric acid, as the magnesia, alumina, silica, oxide of iron, and carbonate of lime, are usually more plentiful in the soil than necessary for the nourishment of the plant. To replace the potash and phosphorus, the amount of manure required will be but small, and M. Gueymard estimates it at five to six tons, or about one-third the quantity usually employed; or, in other words, the use of the leaves and stalks of the hop plant causes a saving of two-thirds of the quantity of the manure commonly applied to hop plantations. If this estimate be correct, it is well worthy of consideration and trial.

A CONVICTION under the Sea Birds Act occurred at Bridlington on Saturday last. Mr. Fraser, india-rubber manufacturer, Sheffield, was charged before a bench of East Yorkshire magistrates with having shot twenty-eight seagulls at Flamborough-head. The defendant was fined in the mitigated penalty of 2s. 6d. for each bird, and 9s. costs. The full penalty for each bird is £1.

APPARATUS FOR GRINDING THE CARDS OF CARDING ENGINES.

MR. SPENCER CRIGHTON, of Ashton-on-Mersey, Chester, and Mr. John Taft, of Manchester, have patented an invention which relates to machinery for grinding the cards of carding engines in which a drum covered with grinding material revolves in contact with the surface of the cards, and at the same time traverses to and fro in order to operate upon the entire surface of the cards. The drum has previously to this invention been arranged with its axis parallel or nearly parallel with the line of direction of its traverse, and when the grinding roller has been operating upon a card roller the axis of the grinding roller has been parallel or nearly parallel with the axis of the card roller.

Referring to our engraving, fig. 1 is a front elevation, fig. 2 a plan, and fig. 3 an end sectional elevation of the machine, representing it as when operating upon two card rollers, figs. 4 and 5 are detached views of portions of the mechanism. In figs. 1, 2 and 3, *a a* are the two card rollers, and *b b* b^1 b^1 are four grinding rollers operating on the card rollers. The card rollers are mounted in the bearings *c c*, which are fitted to slide on the hangers *d d*, shown separately at fig. 4. Each of the hangers is fitted to slide on the cross rail *e*, in order that the distance apart of the hangers may be varied to suit different lengths of card rollers, each hanger being fastened by a bolt d^1 passing through a slot in the cross rail *e*. Each of the bearings *c* is connected to the lower end of a screw *f* by an attachment which will admit of the revolution of the screw, and each screw works in a nut f^1, so that the height of either end of each card roller may be separately adjusted by turning the corresponding screw by means of the hand wheel f^2. Each of the nuts f^1 is formed as a skew spur wheel, and is in gear with a second spur wheel *g* which is mounted on one of the two shafts *h h*, each of the shafts connecting together the two screws, which are employed to adjust the height of one of the card rollers, so that when the shaft rotates the screws will revolve in unison and both ends of the roller will be raised or lowered to an equal extent. The two shafts *h h* are geared together, as shown at fig. 4, and are actuated by the handwheel h^1 and the spurwheel h^2, so that by turning the handwheel in the required direction the two card rollers will be raised or lowered simultaneously.

The card rollers *a a* are each caused to rotate by means of the straps *i i* acting on the pulleys i^1 i^1, which are temporarily affixed to the shafts of the rollers, the straps being actuated by the pulleys i^2 i^2, mounted on the main driving shaft *j*. In the example illustrated, four grinding rollers are employed, the rollers *b b* being mounted on the spindle *k*, and the rollers b^1 b^1 on the spindle k^1, the spindles being fitted to revolve in bearings attached to the sliding carriage *l*. The carriage is fitted to slide to and fro along the bed *m*, and is actuated by the screw shaft *n* which revolves in bearings attached to each end of the bed, and works in a nut attached to the carriage. The screw shaft is driven alternately in opposite directions by means of the cross strap *o* and the open strap *p*, which are driven by pulleys on the main driving shaft *j* and put in motion. The pulley o^1 is fitted to slide on one end of the screw shaft, and the pulley p^1, which is fitted to slide on the outside of the bearing in which the other end of the screw shaft revolves, as shown in fig. 5.

The screw shaft is fitted at one end with a clutch o^2, and at the other end with a similar clutch formed on the back of the bevel wheel p^2, the arrangement being such as that when the pulley *o* is slid into gear with the clutch o^2 and the pulley *p* out of gear with the clutch p^2 the carriage will slide along the bed in one direction. On the contrary, when the pulley *o* is moved out of gear and the pulley *p* into gear, the carriage will move in a reverse direction. This movement of the pulleys is effected by the sliding rod *q* which is fitted at each end with a fork which enters a groove formed in the boss of the pulley, shown in fig. 5. A second sliding rod *r*, shown by dotted lines in fig. 1, is fitted with fingers capable of being adjusted to suit the required length of traverse of the carriage. A projecting piece attached to the carriage comes into contact with one of the fingers when the carriage approaches either end of its traverse, and communicates a sliding motion to the rod *r*, and the rod *r* gives motion to the quadrant or tumbling lever *s*, shown in plan in the small detached figure; this lever is mounted on a stud fixed to the under side of the bed, the lever continuing to derive its motion from the carriage

APPARATUS FOR GRINDING THE CARDS OF CARDING ENGINES.

BY MR. SPENCER CRIGHTON.

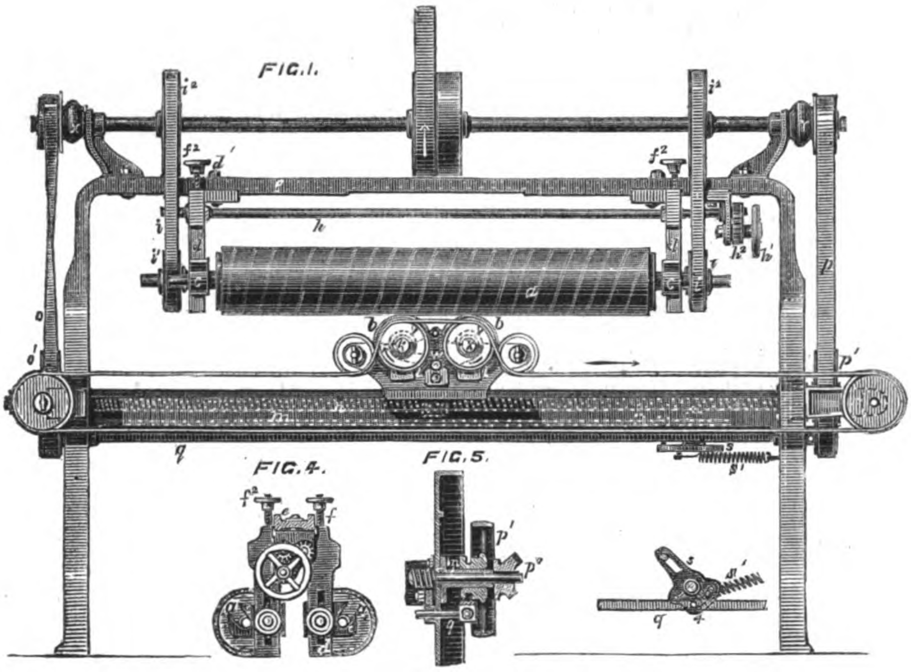

FIG. 3.

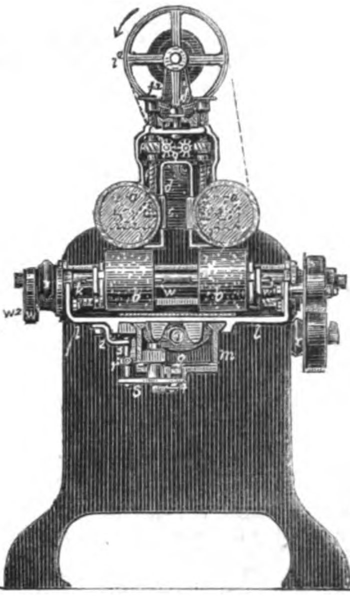

FIG. 2.

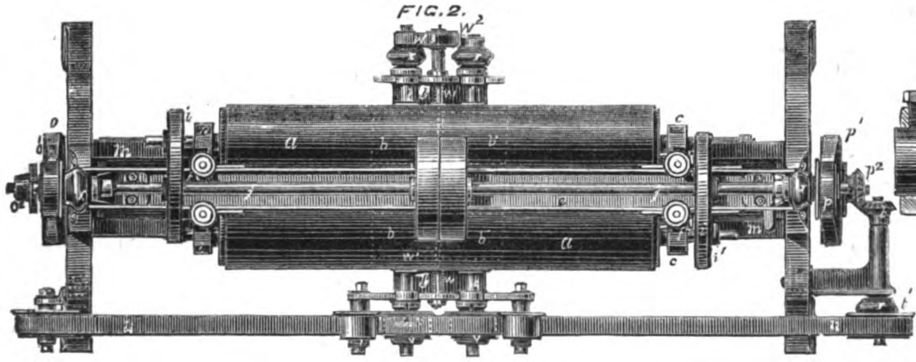

FIG. 6. FIG. 7.

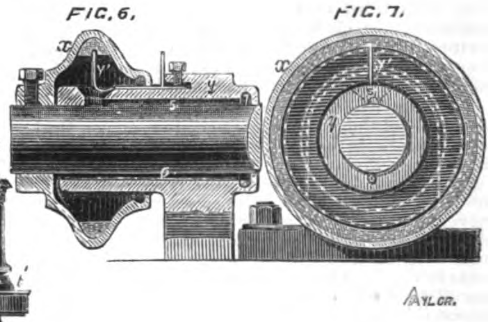


until the point of attachment of the spring s^1 to the lever has to some extent passed the centre of traverse of the lever, when the spring will complete the movement of the lever and one end of the quadrant-shaped slot will strike against a stud fixed to the rod q. The rod will thereby be moved sufficiently to effect the sliding movement of the pu leys o and p.

The bevel wheel p^2 gives motion to the wheel t, and thereby to the pulley t^1 and the driving strap u, the strap being passed partly around the pulleys v v, fixed to the ends of the spindles k k^1, a revolving motion being thus imparted to the grinding rollers. To the sliding carriage is fitted a screw w, in this case formed with a right-hand thread on one end and a left-hand thread on the other end, and on the screw is mounted the double forks w^1 w^1, which enter grooves formed in the bosses of the grinding rollers. On the outer end of the screw is fixed the pulley w^2, which is driven by the end of one of the spindles by the strap w^3, so that when the grinding rollers are revolving in one direction the rollers will be caused to slide on their spindles and to approach each the other, a reverse action taking place when the grinding rollers are caused to revolve in a reverse direction.

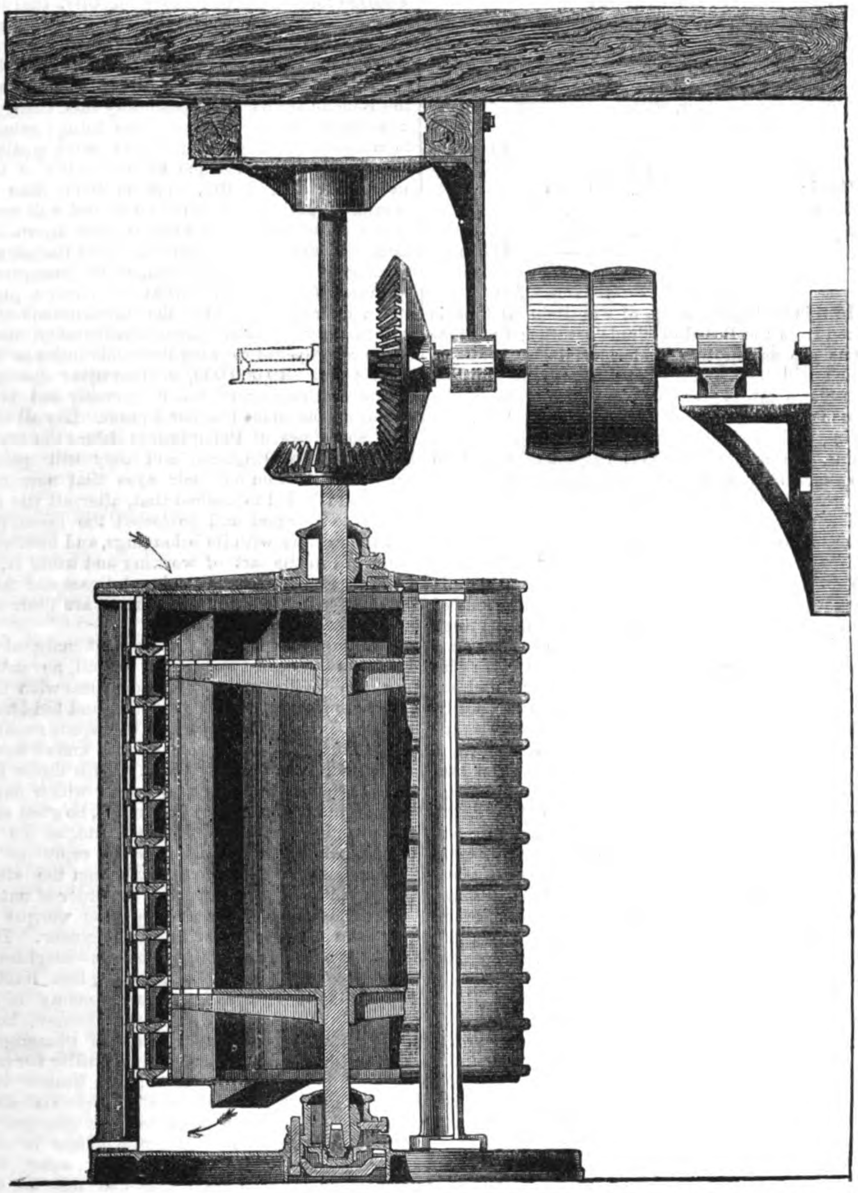
The action of the machine is as follows:—Supposing that either one or two card rollers have been placed in the bearings and adjusted with relation to the grinding rollers, and that the sliding carriage is to the left hand in fig. 1, the driving shaft is set in motion, say, for example, in the direction of the arrow. As the pulley p is in gear with the screw shaft, if the shaft be cut with a right-hand thread the carriage will traverse along the bed of the machine towards the right hand, and at the same time motion will be communicated to the strap u, and the grinding rollers will revolve in the direction of the arrows. As the strap w^3 causes the screw w to revolve, the grinding rollers will slide on their spindles in a direction towards the bearings of the spindles, and as the card rollers also revolve in their bearings, the grinding rollers being covered with emery will grind the points of the card teeth as the carriage traverses. The employment of two grinding rollers to act simultaneously upon one card roller enables the operation to be more quickly performed, at the same time that each grinding roller may be allowed to act more lightly on the card roller than if only one roller was employed.

The carriage continues to slide towards the right hand until the grinding rollers arrive at or near the end of the card roller, when the projecting piece 2 comes into contact with the finger 3 on the rod r, and moves the rod and thereby the lever s until the lever is in a position which will allow the spiral spring to act with sufficient force to continue the motion of the lever without the aid of the carriage. The quadrant-shaped portion of the lever will then strike against the stud 4 and the rod q will be moved to the left hand a sufficient distance to throw the pulley p out of gear and the pulley o into gear, which movement will reverse the direction of motion of the carriage and also of the grinding rollers. The carriage will move towards the left, and as a consequence of the reversal of the motion of the grinding rollers, the rollers will slide on their spindles in a reverse direction, that is towards each other. At suitable intervals, the card rollers are lowered towards the grinding rollers by turning the handwheel h^1, and the operation is continued so long as is advisable, the direction of motion of the carriage and also of the grinding rollers being reversed when the carriage arrives at either end of its traverse.

Lubricators x x made according to Messrs. Crighton and Taft's improvements are employed to lubricate the bearings of the machine, the lubricators being illustrated at figs. 6 and 7, where x is the lubricator and y is the bearing to be lubricated. The lubricator is fixed to the shaft or spindle revolving in the bearing, so that the lubricator will revolve and the oil contained in it will be carried round and will come into contact with the wire y^1, a portion of the oil flowing down the wire and falling into a hole formed in the top of the bearing. The oil thus led from the lubricator flows along the groove 5, lubricating the bearing and shaft in its progress, and falling into the lower groove 6 is returned to the lubricaior, the annular groove 7 preventing to a certain extent an overflow of oil at the opposite end of the bearing. This arrangement is also applicable to other purposes, as, for example, to line shafting and to beater shafts, and especially to shafts running at high speeds. In some cases, pulleys, wheels, pinions, or other revolving parts of machinery may be suitably formed to act as lubricators, as in the case of the pulleys v v, the action of the lubricators being the same as that of the example we have described. We understand that a number of these machines are at work, and they do not fail to give entire satisfaction.

APPARATUS FOR THE TREATMENT OF GRAIN.

BY MR. WILLIAM SECK.



ON THE TREATMENT OF GRAIN.

THOSE of our readers who are practically engaged in producing flour from grain prepared for grinding by the ordinary processes are aware that the greatest difficulty encountered is the separation of the flour from the bran. Assuming the possibility of their complete separation, we have the authority of Liebig for stating that 100lb. of wheat ought to yield from 92lb. to 94lb. of pure flour, and from 6lb. to 8lb. only of bran. According, however, to the present general practice of the trade, with existing machinery, 100lb. of wheat yields, on an average, only from 65lb. to 71lb. of tolerably pure flour (No. 1 quality), while there remains from 8lb. to 15lb. of scrap, or flour of a much darker shade, arising from its being largely intermingled with bran; and 18lb. of bran, ground hulls or integuments. Attempts have been made to correct these decidedly unfavourable results by improving the bolters and boltering implements; nevertheless, but little has been gained by so doing—a want of success which is readily accounted for when the following analysis of the grain is taken into consideration.

By the aid of a microscope, and even by close inspection with the naked eye, the following parts may be easily detected on the grain, viz.:—1. The beard, which consists of a tuft of very small hair tubes, of a dirty white colour. These hair tubes are of much smaller diameter than that of any grain of flour. Under the stones they are reduced to dust, which, owing to the minuteness of its particles, passes along with the flour through the bolters, and therefore cannot be kept separate from it; moreover, owing to the nature of the beard, it follows tha, an additional quantity of other dust and dirt adhering firmly to the hair tubes, will likewise go through the bolters with the flour. 2. The germ, which forms a conical projection on the under part of the grain, and strongly adheres thereto, but, being of a dirty yellow or of a brownish colour, is readily discernible from the rest of the hull. As the germ does not contain any farinaceous matter, such as the kernel, but is of a horny substance and therefore very hard, it is impossible to strip it off under the stones, as is done with the bran, because, like the beard, it grinds into very small particles and passes through the bolters with the flour, to which it imparts a considerably darker shade. 3. The husk, which appears rough and wrinkled, is partly disengaged from the other skins, loosely envelopes the kernel, soon becomes very dry and hard, and, under the stones, breaks up into small prismatic ingredients, which, by passing easily through the bolters, not only give a dismal dark shade to the flour, but appear as coloured spots upon it.

The combined weight of the beard, germ, and outer skin, is equal to about from 1 to $1\frac{1}{2}$ per cent. of the entire weight of the grain. Although it might appear that so small a quantity as from 1 to $1\frac{1}{2}$ per cent. of such matters could not materially deteriorate the quality of the flour, it is nevertheless a fact that it does so, inasmuch as it reduces the yield of No. 1 flour from the grain to the extent of 10 per cent.; a fact which can be readily demonstrated by mixing 1lb. of dust with 10lb. of flour, which will thereby become converted into a dark spotted mass, representing the lowest quality of flour. As the above-mentioned ingredients, for the reasons given, cannot possibly be separated from the flour, it becomes evident that they must be removed from the grain before its subjection to the grinding process.

The chief mistake hitherto committed, in the cleaning of grain, has been its submission to wire brushes, sharp surfaces of stone, corrugated sheet iron, &c., the latter being the most generally used, and revolving cylinders or covers commonly called "robbers" being employed. So long as the surfaces remain sharp, whenever the grain comes in contact therewith, it is injured by having its hull cut open. A close inspection of wheat treated in the manner referred to will amply bear out this statement. Such injuries to the grain occasion the premature breaking up of the bran in the process of grinding, and cause it to be largely ground up into flour. But, as the hulls of the grains contain a considerable quantity of silicate, the sharpened surfaces become rapidly blunt by the constant rubbing, until at last little or no effect is produced upon the grain by its passage through the machine. Hence it follows that machines based upon this mode of operation have the effect of damaging the grain, until they ultimately become utterly useless, though nevertheless, at the same time, absorbing considerable motive power. In order to partially remedy these serious defects, it is found requisite to employ two or more apparatuses of the expensive construction in question, one at least of which is usually kept sharp; but although they are kept in repair at considerable cost, and involve much trouble, the results of their working are anything but satisfactory.

Moreover, they necessitate an excessive amount of supervision, so that, altogether, when the quality of the flour produced is taken into consideration, loss of money results from their employment. So defective is this system, that in large mills recently erected in Hungary, the old system known as the "spitzgang" appears to have been resorted to, only, however, to be again relinquished, because it, too, very imperfectly removed the hulls, while it was at the same time equally damaging in its effects upon the grain. It is true that some machines having cylinders without corrugated surfaces containing fixed or movable wings have been in use, but they have been considered equally ineffective, inasmuch as the grain by its own weight passes too rapidly through the apparatus. Only the winnowing effected during the process is worthy of notice, because it certainly does at least remove such small particles of dirt and dust as do not adhere firmly to the grains.

Now, Mr. William Seck, a Prussian inventor, has devoted himself to the subject for a number of years, during which time he has spent a considerable amount of money in constructing and perfecting machinery for hulling and cleaning grain. His experience is that no thoroughly satisfactory result can be attained by direct operation of the machinery against the beard, germ, and wrinkled hull of the grain, but that the desired end can be completely effected by working the grains among one another by means of centrifugal force. The husks of grain contain a considerable quantity of silicate, a substance so hard that even the hardest French millstones will not resist it for any length of time. For this reason, no corrugated iron or steel, or other sharp surface, would be sufficiently lasting to scour the grain for any considerable period. It is therefore submitted by Mr. Seck that grain should be treated against grain on the same principle that diamonds are polished by diamonds. By repeated trials, it has been conclusively proved that, in order to effect a thorough polishing and raising of all prominent parts of the grain, it should be subjected to a velocity of 3,000ft. per minute, in a centrifugal apparatus, and that its treatment therein should be continued for a period varying from three to four minutes, according to the nature of the grain operated upon. Upon this principle, Mr. Seck has based the system of which the following is a brief description, the apparatus being illustrated in part section in the accompanying engraving. We may here state that we recently examined one of these machines at the offices of Mr. Seebohm-Ultzen, 21, Mark-lane, London.

The machine consists of a vertical casing, having a number of rings or circular shelves around its interior, and containing a rotating drum provided with vanes which take into the spaces between the rings or shelves. Part of the outer casing is constructed of sheet iron having perforations through which the currents of air escape into the dust or bran chamber, carrying with them

all dust, dirt, bran, &c. By the rotation of the drum, the grains are carried round upon the shelves at a velocity of 3,000ft. per minute, thus rubbing against each other most effectually. The outlets from one shelf to another are so arranged as to keep the grain under treatment during the required period of from three to four minutes. The velocity above mentioned has been determined by ample tests, and adjusted to completely remove all injurious parts, without in any way damaging or heating the grain. As regards wear and tear, it may be observed that by the working of the grains against one another, as described, combined with the peculiarity of the apparatus, all undue stress upon the various parts of the machine is entirely avoided. In proof of this fact, we are informed that a number of these machines have been constantly at work for about three years past, without requiring any repair or showing any signs of wear, and that they continue as efficient in their operation as they were at first starting.

From our description it will be seen that not only does Mr. Seck's apparatus treat the grain in the only appropriate manner, but that the grain is simultaneously subjected to perfect ventilation such as is not attained in any other machine. The ventilation being simultaneous prevents the adhesion to the grain of any injurious particles which should properly be separated from it. Besides having their beards, germs and wrinkled husks removed, the grains likewise receive a certain polish, so that, on leaving the apparatus, they are pleasant to the touch and ready to go at once under the millstone. The Royal Prussian Government has exclusively adopted this system, and have set up a number of these machines in their mills attached to the Royal Marine and Military Departments at Dantzic, Coblentz, &c.

In a well fitted Austrian mill, the grain treated by Mr. Seck's apparatus yielded 47 per cent. of No. 0 and No. 1 flour, as against 32 per cent. obtained from grain treated in well arranged apparatus according to the old system, in which both robber and spitzgang were employed, while the inferior qualities of flour resulting from the grain passed through Mr. Seck's machine were much better than those from the grain treated by the other process. The official trials ordered by the Austrian Government, and superintended by a staff of officers delegated by the War Department, with a number of other gentlemen in office, gave equally good results. Under the system employed at the military steam flour mills in Austria, the yield of 100lb. of rye of the standard quality was as follows, viz.:—85lb. of flour, 12lb. of bran, and 3lb. of dust, including loss. By Mr. Seck's process, the following results were obtained from 100lb. of somewhat inferior rye, which happened to be at hand in the mill, the rye, in this instance, being of the quality produced in Pilsen, where the trials took place, viz.:—

1st Trial.

89·59lb. of flour
0·91 „ „ black flour
3·88 „ „ bran
2·28 „ „ ligneous husk (when cleaning)
0·09 „ „ dust including loss (when cleaning)
0·32 „ „ dust including loss (when grinding)
The flour being likewise far superior in quality to that yielded by the other process.

2nd Trial.

A second trial, in which no scrap or black flour was produced, gave:—
92·51lb. of flour
2·84 „ „ bran (when grinding)
2·48 „ „ bran (when cleaning)
0·09 „ „ dust including loss (when cleaning)
2·27 „ „ dust including loss (when grinding)

We may add, in conclusion, that there are now some 300 of Seck's machines at work on the Continent, and, as far as experience goes, they give every satisfaction. At the annual meeting of the Union of Millers, held at Leipsig last month, one of Mr. Seck's machines was exhibited, and, we are informed, obtained the only first-class prize medal, a resolution being passed by the Union recommending the apparatus for general adoption.

THE PAYING AND NON-PAYING WEIGHTS PULLED BY THE LOCOMOTIVE ENGINE IN 1867.

By Mr. B. Haughton, C.E.

(Concluded from page 28.)

SOME persons may take exception to the rating of the assumed items, but, even should they be found strained or faulty, which I have taken all pains to prevent, the amount of their error, however largely it may be estimated, cannot materially affect the issues.

Weight of the average goods train was, in 1867—

Non-paying load, viz.:—

Engine and tender . .	50 tons	
2 breaks	8 „	
6 goods trucks at 3½ tons each, to carry 3 tons .	21 „	
6 mineral trucks at 3½ tons each, to carry 7 tons each	21 „	
		100 tons
Of the above, to be sent back as empties, 2 goods trucks, 6 mineral trucks	28 tons	
¼ engine and tender, with empties	12 „	
		40 „
Paying load.		
Goods	19 tons	
Minerals	41 „	
6½ head live stock . .	1 „	
		61 tons
Total . . .		201 „

In this table, the detail of the item 61 tons is taken from the Board of Trade returns; the other items are assumptive (under certain restrictions, which will be apparent), still not to be omitted. These two tables give the average weights of the passenger and goods trains of the year; by multiplying their several sums by the total numbers of trains, passengers and goods respectively, run in the year as given in the returns, I have arrived at the great totals given before.

The second point to which I have asked your attention is that of the immense excess of the non-paying weight of the trains over and above the paying weight. This is a subject which is frequently treated in the scientific publications of the day, and which has been discussed at meetings of this Society, but I am not aware that it has been hitherto considered in connection with the Board of Trade returns. In the annual address which I had the honour to give to this Society in October, 1868, I alluded to the subject of non-paying weight. I then gave an estimate of what I believed to be the proportions in which these two divisions of the total weight of the train are to be found. The non-paying weight, large as it was, I now find was understated, as shown by the astounding results extracted from the returns. This was in part owing to the fact that the figures were drawn from a much smaller railway circle than that from which the returns immediately before us have been computed.

The proportions of the paying weights of trains run in 1867 were, viz.:—

Passenger Trains.

Paying weight, 4·89 per cent. of the total weight of the train.

Goods Trains.

Paying weight, 30·34 per cent. of the total weight of the train.

Total Passenger and Goods Trains.

Paying weight, 16·67 per cent. of the weight of the whole train.

Or, in simpler phraseology, it takes 19 tons of train equipment to carry 1 ton of passengers, 2¾ tons of the same to carry 1 ton of goods, and, in gross, 5 tons of equipment to carry 1 ton of paying load.

That the public are not acquainted with these facts is, I believe, the secret of their discontent with the management of our railways. They place themselves willingly under the direction of theorists, who are not competent to realize the situation. Relieve them from this state of suspense in which they are placed, make them familiar with the reason why they cannot hope for a reduction of fares, and they will rest content, and railway property cannot fail to be the gainer thereby. Show them that the experience of the Post Office cannot be taken as a guide for the management of railways, because a letter weighs practically nothing, as I have endeavoured to show in the address beforementioned, and that its numbers may be increased almost indefinitely without extra cost of carriage, whereas a passenger will weigh 2 tons, including his share of train equipment; and, moreover, that each passenger carried in addition to the usual numbers will bring an additional weight of 2 tons with him. Show them that the fares charged by excursion trains cannot be taken as a guide, because the conditions under which they are run are not those required in the conduct of the common traffic trains of the country. Show them that the extremely low fares charged on the Belgian railways cannot be taken as a guide, because, firstly, what are commonly called the Belgian railways, and notably so in the second report of the Railway Commission of 1868, are not the Belgian railways, but only a fraction of them, that is to say, 535 miles out of 1,819; secondly, that they were constructed by the Government, before private railway enterprise had commenced in Belgium, who naturally selected the most promising lines of country, and are, in fact, possessed of the cream of the traffic of the land; thirdly, that these lines have cost £18,000 a mile as against £36,000 for the English lines; fourthly, that these lines have been charged with no parliamentary expenses; fifthly, that land is of far greater value in England than in Belgium; sixthly, that labour is dearer in England; seventhly, that the speed of the Belgian trains is considerably less than that usual in England. That all these things combine to make the working of railways more costly at home, and so to produce higher tariffs of fares and rates; and, finally, that no later than this month, M. Malou, Belgian senator, and well versed in the railways of that country, has shown in a pamphlet which he has published, that the glowing promise of a new railway era, to be inaugurated by these gifted Belgian legislators, is only a juggle and a delusion, and that the Government must immediately raise their fares considerably, unless they are prepared to work their 535 miles of line, having cost £10,000,000, with an utter disregard of the ordinary principles of economy and trade, and at an enormous loss per annum. Lay all these facts and views of the question before the travelling public of England, and they will quickly wipe the film from off their eyes that now rests there, and be led to confess that, after all, the men who have invented and perfected the locomotive and the railway with its belongings, and instructed the world in the art of working and using it, are as likely to know how to tend and direct and manipulate it with skill and sagacity, as are their continental and other pupils.

The English engineer knows that natural and economic laws must eventually prevail, no matter how the public may wish to dispense with their action; he knows the ways, paths, and tendencies of these laws; he knows how to respect them, as respected they will be; while he also knows how to bend them to his educated will. With these laws as his guides, and with the forces which nature permits him to wield as implements, he goes on in a safe and sure road of progress, and, as he advances, hardly turns his head to reply to the dreamers and triflers, who preach from the stump and the journal the reversal of the order of nature.

This immense dead or non-paying weight has ever been a difficulty with the engineer. Dead weight has no doubt increased of late—engines are made heavier, hence more adhesion, less liability to become derailed and greater economy of fuel in working; carriages are made longer, hence there is more space for the legs of passengers; they are made higher, hence more facility for moving when in an erect position; the timber is of larger scantling, hence more steadiness and durability—all these changes have been changes for the better, the traveller in consequence is more convenienced as well as physically safer than before—the latter a boon that can not be over estimated; he is actually 1,000 per cent. safer at present sitting in a railway carriage in motion, then when walking in the London streets. The Briton of the age, in short, travels fast and securely; faster, indeed, than the representative individual of any other nation; he is in the condition of the man who lives fast, and builds a large and comfortable mansion for his gratification; its dimensions are greater than are absolutely necessary for his wants, yet he can afford the cost and he defrays it. The Briton must do likewise if he wishes to travel fast.

Reduction of non-paying weight is practicable, but it implies a reduction both of the rate of speed and of convenience, and it is not likely that it can be attempted in the face of the long enjoyment of these luxuries which the public have possessed. The receipts per mile from the 73¼ persons who travelled per train' run in 1867, were, viz.—

	Persons.		s. d.	Corrected income per mile.
1st class . .	8¼	at 2d. per mile	1 4½	1 2¾
2nd class . .	20	at 1½d. „	2 6	2 3
3rd class .	45	at 1d. „	3 9	3 8
	73¼		7 7½	7 1¾

The column headed "Corrected" shows the correct figures, having made the proper deductions because of return tickets, which may be taken at 60 per cent. of the whole number of tickets issued for 1st and 2nd classes. This 7*s.* 1¾*d.* per mile must not be confused with the 4*s.* 9*d.* per train mile of the returns; the first is the income per mile run by the 73¼ passengers, the average mileage run by each passenger being 12¾ miles, while the average mileage per train was 19 miles.

The following details may be useful, viz.:—73¼

passengers carried in each of the 3,924,624 passengers trains run. Paying and non-paying weights of each train 143 tons, being a total weight per passenger of 2 tons. Total weight of train per 1 ton of passengers equal to 20 tons 8cwt. 60 tons goods and minerals, and 6½ head of live stock carried in each of the 2,403,866 goods trains run, paying and non-paying weights of each train 201 tons, being a total weight per 1 ton of freight of 3¼ tons.

Each passenger train, weighing a total of 143 tons, was pulled over a distance of 19·08 miles, bringing a revenue of £4 11*s.* 4¾*d.*, equal to

	d.
Per mile ton of paying weight . . .	8·2
Per mile ton of total weight of train . .	0·40

Each good train, weighing a total of 201 tons, was pulled over a distance of 30·64 miles, bringing a revenue of £8 19*s.* 2¾*d.*, equal to

	d.
Per mile ton of paying weight . . .	1·14
Per mile ton of total weight of train . .	0·34
Passenger revenue per head per train mile .	0·78
Passengers revenue per head per mile actually run by each passenger . . .	1·17

These figures lead to the vexed question, viz., the relative paying properties of passengers and goods, which is shown in the items as above, viz.:—

	d.
Passenger revenue per mile ton of total weight of train	0·40
Goods revenue per mile ton of total weight of train	0·34

These figures are not strictly accurate, while sufficiently so for our purpose, because we know from the passenger revenue per head per train mile of 0·78*d.*, that each passenger cannot have travelled the whole 19·08 miles run by the passenger train. I find that the actual distance run by each passenger was about 12¾ miles or ⅜ more than the distance run 1855, as given by Mr. Robert Stephenson in his address to the Institute in 1856, before alluded to. The precise distance run by each ton of goods pulled is not so easily found. However, all things considered, the deductions for these drawbacks of passenger and goods mileage from the 19 miles and 30¾ miles run will not cause any material error in the representative fractions 0·40*d.* and 0·34*d.*, the incomes per hor. mile ton, respectively, as the deductions would only apply to the paying weight sections of the train, which in each case is small as compared with the total weights.

These fractional figures would place the advantage on the side of passenger traffic to the extent of 0·06*d.* per hor. mile ton, but against such is to be placed the serious debit of 90 per cent. more speed, also 90 per cent. more of capital invested in vehicles, valuing carriages at £200, and trucks at £60 each, the capital invested in the latter being, viz.:—

Carriage capital, per ton of freight pulled per annum	3s. 9d.
Truck capital, per ton of freight pulled per annum	2s. 0d.

While to its credit is to be placed, say, 50 per cent. less concussion, and the carrying of 75 per cent. more freight per vehicle, &c., &c., viz.:—

27,354 carriages carried 27,472,368 tons, or 1,004 tons per vehicle.

247,048 trucks carried 146,635,826 tons, or 593 tons per vehicle.

A Debtor and Creditor account would stand thus—

PASSENGER TRAFFIC,
AS AGAINST
GOODS TRAFFIC.

Dr.	*Cr.*
90 per cent. more speed.	17 per cent. more revenue per mile ton of total weight pulled.
90 per cent. more vehicle capital invested per 1 ton of paying load pulled.	50 per cent. less concussion, viz., load carried 12cwt. per foot of wheel base, as against 20cwt. to 40cwt.
	75 per cent. more paying load carried per vehicle per annum.
	12 per cent. greater facility in reception and delivery of paying load.

I shall not now strike the balance; the advantage, however, at first sight is on the side of goods traffi·. If the two sides should be found on a line, it will be a remarkable proof of the sagacity of railway managers, in that they succeed in making the two great divisions of traffic revenue contribute equally to the general account.

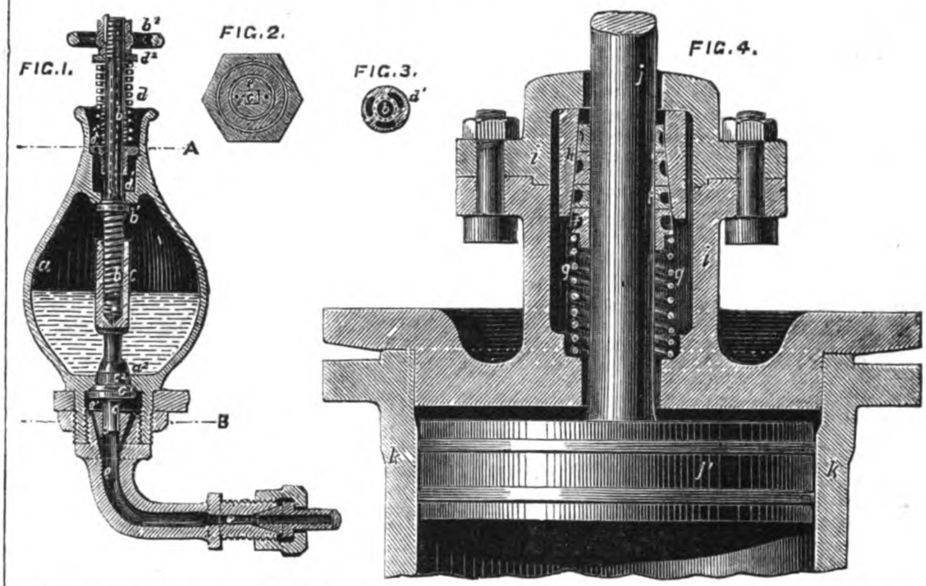
I must not forget to acknowledge my obligations to Mr. Frederick T. Haggard, of Burnham House, Kent, for the assistance which I have received from him while investigating this question, as well as for the hints which I have taken from his valuable pamphlet entitled "A Mile of Railway," published last February. He will, I trust, permit me to take this opportunity of thanking him for his kindness in giving me that information whenever sought, which his grasp of the subject and general practical knowledge of statistics and finance enables him to command. The moral which I have endeavoured to make this paper convey is this: that so long as the railways of the United Kingdom shall carry passengers and their train equipage at 0·40*d.*, or two-fifths of a penny, per ton per mile, at an average speed, while running, of thirty-four miles per hour, and goods and minerals, with their accompanying dead weights, at 0·34*d.*, or one-third of a penny, per ton per mile, at a speed of eighteen miles per hour, the public cannot complain.

If they will take a common sense view of the question, and compare these rates and speeds with those of such other modes of traction as they are familiar with, and further compare them with those of other countries, giving their own country credit for the many and great conveniences and accommodations which the system confers upon them, as well as taking due cognizance of the quality and price of the material out of which the fabric is made, and upon which it is built up, I feel assured their verdict will agree with that before quoted—that in the matter of railways they are "the best served community in the world." These returns disclose the strange facts that the average British passenger weighs 2 tons with train accessories, and that the ton of goods, &c., weighs 3¼ tons; by no known processes can these enormous multiplication of original net weights be reduced, consistent with affording that amount of personal security, and comfort, and accommodation now enjoyed; let them in their future deliberations on this subject relinquish the idea which has so long clung to them, and which has been so ingeniously and persistently placed before them, that a railway passenger is a featherweight—a letter or a newspaper, as it were—and that he may be treated accordingly, let them try to realize the facts as stated, as to the actual total of paying and non-paying weights pulled, and the enormous energy developed in order to produce the effect expressed in the figures as before given, viz., 25,512,646,408 hor. mile tons.

These, combined with the figures representing the wear and tear of material, and the labour expended in the maintenance of the system, will, perhaps, convince them of what an exacting, devouring, and insatiable monster it is that they have called upon to minister to their lately-born wants, and will go far to reconcile them to the existing tariffs of fares and rates, which, no doubt, competition and the wish to act in a just and liberal spirit to all parties concerned on the part of railway executives, has already reduced to the lowest admissible rate. I believe that these are amongst the "things not generally known," and that when generally known they must tend to promote and strengthen that cordial understanding which ought to exist between the ra lway proprietor and the traveller by railway, and so without fail to increase the confidence of the investing public in this great property, and as a necessary sequence to enhance its money value.

LUBRICATING APPARATUS AND PACKING.

BY MR. F. HOLT.



LUBRICATING AND PACKING STEAM ENGINES.

THE object of the invention we are about to describe is to reduce the friction in the working surfaces of steam engines by means of an improved lubricating apparatus, and to prevent the escape of steam in the stuffing boxes by means of an improved metallic packing. It has been patented by Mr. F. Holt, of Gorton Foundry, Manchester, and is illustrated in the annexed engraving, in which fig. 1 is a vertical section, and figs. 2 and 3 transverse sections of the lubricator. This apparatus consists of a vessel *a* provided above and below with a valve seating, marked respectively a^1 and a^2. The spindle *b* of the upper valve b^1 is screwed into the spindle *c* of the lower valve c^1, and the valves b^1 and c^1 are held up against their seatings a^1 and a^2 by the spring *d*, which abuts against the fixed washer d^1, shown detached in fig. 3, and the loose washer d^2 placed below the boss of the handwheel b^2 fixed to the spindle *b*. The upper valve is opened to pour the lubricant into the vessel by screwing the upper into the lower spindle, and it is closed by turning the spindle in the contrary direction. When the cylinder requires to be lubricated, the lower valve c^1 is opened by turning the upper spindle *b* to allow a portion of the lubricant to flow out of the vessel *a* through the elbow pipe *e*, the upper portion of which serves as a guide for the square lower part of the spindle *c*, as shown in fig. 2, which is made with diagonal perforations e^1, to convey the lubricant into the pipe *e*. The quantity of lubricant allowed to escape is governed by the diameter of the shoulder e^2 on the spindle *c* passing through the opening above the seating b^2.

This apparatus is particularly beneficial when applied to the cylinders of locomotive engines, as the lubricant is only required when the steam is turned off, and when the engine is running down an incline or is in motion by its own inertia. In condensing engines the vacuum formed in the pipe *e* causes the valve c^1 to be opened at every stroke of the engine to the extent of the back lash in the screw on the spindle *b*, screwed into the socket of tho spindle *c*, thus rendering the lubricator self-acting in all cases where a partial vacuum is formed under the valve c^1. Some of these lubricators are now working on the North British, the Great Southern and Western of Ireland, and other railways, where they give every satisfaction. They are

manufactured by Messrs. Storey and Sons, Knott Mill Works, Manchester.

Fig. 4 is a section of Mr. Holt's metallic packings, which are adapted for the stuffing boxes of locomotives and other steam engines. The packing consists of two or more packing rings *f*, which are cut through in one part. These rings are slightly conical at their circumference, and are pressed by the spring *g* into the conical bush *h* loose in the stuffing box *i*. The end of the bush *h* being faced to the end of the stuffing box prevents the escape of steam, and allows the packing to adapt itself to any slight irregularity in the position of the piston rod *j* of the piston *j* [1] working in the cylinder *k*.

CHEMISTRY OF COMBUSTION.*

No. I.

By MR. W. M. HENDERSON.

THE following notes, relating to the subject of steam boilers, are offered to those interested in the matter of steam boiler inspection. The information conveyed has been condensed mainly from the works of William Fairbairn, Robert Armstrong, and Charles Wye Williams, interspersed with the results of twenty years' practical experience of the writer.

CHEMISTRY OF COMBUSTION.

Ordinary combustion is the combination of oxygen with the combustible element of fuel. In coke and charcoal, carbon is the sole combustible element, while in coal there is hydrogen also. In 100lb. of good coal there are about 84lb. of carbon and 6lb. of hydrogen; the residue is composed of matter that does not assist combustion, but sometimes retards it by forming clinkers, and otherwise obstructing the process. The hydrogen furnishes weight for weight, about four times as much heat as the carbon, or 22 per cent. of the whole. The products of combustion are:—

Steam	H 2, O 1	in weight as 1 to 8.	invisible and incombustible.
Carbonic acid	C 1, O 2	" " 6 to 16	" " "
Carbonic oxide	C 1, O 1		" " "
Smoke			

The first part of the process of burning coal consists in distilling, or expelling by heat, the hydrogen, in the gaseous form, combined with the carbon in one or two proportions, forming carburetted hydrogen, or coal gas, H 2 C 1 in weight, as 1 to 3, and bi-carburetted hydrogen or olefiant gas, H 2 C 2 in weight, as 1 to 6, the latter forming 10 per cent. of the whole. Taking this estimate, we find that 9-10ths of the 6lb. of hydrogen combines with three times its weight of carbon, taking up 16·2lb. of the latter, and 1-10th combines with six times its weight, taking 3·6lb., together taking 19·8lb. from the 84lb. of carbon in the 100lb. of coal, making 25·8lb. of carburetted gases, to be burned above the coke, leaving 64·2lb. of carbon to be burned in the form of coke.

Now, to burn 1lb. of hydrogen requires 8lb. of oxygen, and the product is 9lb. of aqueous vapour; and to burn 1lb. of carbon requires 2 and 2-3rd lb. of oxygen, the product being 3 and 2-3rd lb. of carbonic acid (the resultant of perfect combustion). Hence, to burn the 6lb. of hydrogen requires 48lb. of oxgen, and to burn the 19·8lb. of carbon, combined with it, requires 52·8lb.; altogether 100·8lb. of oxygen to burn the gaseous portion of 100lb. of coal. To burn the 64·2lb. of carbon that remains upon the grate, after the expulsion of the volatile gases, would require 172·2lb. of oxygen, the sum of both being 272lb. of oxygen to consume 100lb. of coal.

Atmospheric air consists of volumes N 4 O 1 in weight, as 28 to 8, the oxygen being but 1-5th of its bulk, and the quantity required being as 2 to 1 of the carbon, in order to produce perfect combustion; the quantity of air employed will, therefore, be ten times the volume of the gas to be consumed. From this it will be seen that 1,224lb. or 16,320 cubic feet of air must be admitted to effect the combustion of 100lb. of coal, allowing that 60 cubic feet of atmospheric air are required to produce each pound of oxygen. The quantity chemically required for 1lb. of coal is, therefore, about 164 cubic feet, of which 60·8 enters into combustion with the volatile gases, and 103·2 with the solid portion of the coal. At the general temperature of the furnace, 1,000deg., these products of combustion expand about three times the original bulk of the air, *i.e.*, 164 $\times$ 3 = 492 cubic feet of air and gas to be passed with a velocity of 36ft. per second.

The formation of carbonic oxide is known to be greater in a thick fire with a poor draft than in a thin fire with a strong draft; in the former case there may be perfect combustion, producing carbonic acid in the lower part, and the acid so produced may take up another equivalent of carbon in the upper part of the fire, and thus waste half of the carbon, which passes off in the form of carbonic oxide. The remedy for this is a judicious introduction of air above the fire. But to effect the combustion of either gas or solid carbon, it is necessary that the oxygen which is to combine with it should be brought within the sphere of its attraction; the two must be brought into intimate contact and touch, or nearly touch, while the temperature is favourable. The gas from a burner or candle will not attract oxygen at ¼in. distance; practically, they must be intimately mixed before they can burn.

If these conditions be not fulfilled, the combustion will be incomplete; the hydrogen, possessing the strongest affinity for oxygen, will first combine and leave the carbon free, in the form of black powder, which will mix with the vapour resulting from the combustion of the hydrogen and with the nitrogen gas, and constitute what is called smoke. Now, if this smoke, containing, as it often does, valuable quantities of uncombined carbon, comes in contact with cold surfaces, it loses heat, falls to the temperature of steam, and its combustion is then practically impossible. At the moment the hydrogen and oxygen combine to form water they are at a white heat; if, at this moment, there be present a sufficient excess of oxygen the carbon will be consumed, but if, at this moment, the carbon is not also combined, smoke ensues. The problem is to burn the gas in the act of distillation at one operation.

In a properly constructed steam boiler an average of 10lb. of coal will be burned per square foot of grate per hour with natural draught, and as 1lb. of good coal will evaporate about 8lb. of water, 80lb. or about 10 gallons of water will be evaporated for each square foot of grate surface per hour. When blast is employed these quantities may be doubled. The furnace room should be from 1·5 to 2·5 cubic feet per square foot of grate, according to the consumption of coal. The boiler room should be about 1 cubic foot for each square foot of heating surface. The area of heating surface should not be less than 1 square foot per pound of coal consumed per hour, or, where it can be obtained, as 18 to 1 of the grate surface. Area over bridge, through flues and chimney, 2 square inches per pound of coal consumed; or, taking 12lb. of coal as being the maximum that can be burnt upon a square foot of grate, a calorimeter of 24 square inches per square foot of grate surface is recommended for natural draught. Ash pit entrance for air, one-half area of grate. Area of orifices for admission of air above grate should be about 4 square inches for each square foot of grate, more or less, according to the gas-generative qualities of the coal and extent of combustion. In regard to the disposition of the heating surface, it should be as concentrated as possible, as experiments have shown that the first foot of the length of tubes in horizontal boilers, next the furnace, was equal in evaporative value to the furnace itself; that the next 4ft. were not equal to the first foot, and that the fifth foot possessed very feeble generative properties. It is, therefore, considered there is no gain in having tubes in such boilers over 6ft. in length, and that the effective length of flues in horizontal boilers is arrived at within very moderate limits, probably not exceeding the maximum of 20ft. The reason of this is quite obvious, as a boiler may be of such length that the generative value of the heated gases may be entirely expended before they have reached the extreme end, in which event, it is plain, a positive loss is entailed; for the water which has been heated at the furnace end, and the steam which has been raise there, must be deprived of a portion of that heat again, in order to raise equally the temperature of the water at the cold end.

For many years, within the experience of the writer, it was the practice to construct steam boilers from 40ft. to 60ft. in length, with a view to use up the whole of the heat resulting from combustion of the fuel. Some of these very boilers, after being cut in two—the one-half only retained—gave such improved results as to have at last completely exploded that plausible theory. Quite an important feature in the generation of steam is to be found in the manner of conducting and applying the heated gases to a steam boiler. They should be led at once through the body of the water, *i.e.*, through flues or tubes, and if a return can be made, with a view to economy, to make such a return under the shell, and if practicable, with a still further view to economy, over the shell of the boiler. No doubt much of the merit pertaining to the Cornish type is due to this manner of construction. Of the double-flue description, the Butterley, or Fish-mouth, or, as it is better known in this country by the more modern name of the Corliss boiler, is far preferable to the common flue boiler, where the heat passes backwards, first under the boilers and lastly through the flues, passing the most effective heating surfaces at the time it has no real generative value. Another matter of eminent importance to this subject, and one which has not received that degree of attention its worth demands, is that of supplying to the uninflamed gases of the furnace the necessary amount of oxygen to insure perfect combustion, which otherwise would escape unconsumed into the atmosphere. This is the only method of obtaining from the fuel the maximum of heat it is capable of yielding. By experiment it has been shown that the saving effected in coal, by a judicious attention to this particular, has been from 12½ to 33 per cent., accompanied with a perfect freedom from smoke, as all smoke consists of a portion of the carbon of the fuel passing off unconsumed.

It is believed this discovery, like many others of great merit, was the result of mere accident, not being brought about from any hope of economy, but the desire to suppress the intolerable nuisance of smoke, emitted from the furnaces in the manufacturing districts of England from the combustion of bituminous coal. In the combustion of anthracites, as largely employed in this country, no great objection has been found to the comparatively colourless smoke emitted, and so it has been allowed to pass unheeded; but as anthracites contain more carbon than bituminous coals (as high as 90 per cent.), even more air is required for their combustion than the latter description; and unless this air is supplied, large quantities of carbonic oxide will be constantly discharged into the atmosphere, carrying off a large percentage of the carbon of the fuel, without contributing in a proper manner to the generation of steam. As regards the form of the furnace many curious ideas exist. It has been contended that the crown sheet should be low enough so that the flame may impinge with force upon it. The value of position of the heating surfaces has been settled for us by some authority long ago, and has been religiously copied in all our works of modern compilers, who inform us that only horizontal surfaces should be considered and calculated as direct heating surface; that vertical sheets must only be taken at half value, and that the upper half of the circumference of flues alone are effective. Now, caloric being a body which radiates in all directions, the transmission of heat through the different parts of a steam boiler cannot vary to such an extent as the above calculations lead us to believe. It is true the heated gases have a tendency to rise to the highest points, but where the calorimeter is properly calculated to carry away the net products of combustion, it cannot ascend in this manner, and must tend to diffuse itself over every avenue in order to effect an exit. A large firebox or capacious furnace is necessary to produce a thorough admixture of the gases of combustion, which undoubtedly should take place in that part where the necessary heat is present to insure this result. The concentrated action of the heated currents upon the firebox must be more injurious with a low crown sheet than a high one; in either case it would be bad enough were it not for the great difference which exists between the temperature of the box and the water within the boiler, which seldom or never exceeds 400deg., whereas that of the furnace may probably reach as high as from 1,500deg. to 2,000deg.

The absorbent material should be as thin as possible, therefore of the highest standard of quality, in order to save time in the transmission of heat, and to effect a rapid evaporation of the water contained within the boiler. As regards the effective evaporating results, or transmission of heat through metals, this depends upon the three following properties:—First, the resistance of the surface next the fire to absorption of the heat; second, the resistance of the internal particles of the metal to the conduction of heat; and, third, the resistance of the surface next the water in giving off the heat. The relative evaporating power of wrought iron, brass, and copper are respectively, 100, 125, and 156.

* "Journal of the Franklin Institute."

Legal Intelligence.

VICE-CHANCELLOR'S COURT.

JULY 8.

(Before Sir W. M. JAMES.)

HEWITT *v.* COOPER.

THIS was a motion, on the part of the plaintiff, for an injunction restraining the defendant from infringing a patent, granted to the plaintiff in 1860, for sockets for whip handles, the main feature of the invention being that the plaintiff inserts in the socket a steel spring covered with leather which clips or catches the whip handle. The defendant had sworn that the sockets made by him differed from the plaintiff's invention in that they were lined with leather and gutta-percha, and had no spring. But, during the hearing of the motion, one of the defendant's sockets was cut open, and, it appearing that there was whalebone inside the leather, the Vice-Chancellor thought the affidavit seemed so much like a deliberate attempt to deceive the Court, that he granted the injunction as prayed, giving leave to defendant to move to dissolve it if he satisfied the Court that the silence of the affidavit as to the whalebone was not fraudulent or material.

On the part of the defendant, any fraudulent intent was disclaimed, and the form of the affidavit was explained as arising from the fact that the whalebone did not act as a spring, and was, therefore, considered a matter of no importance.

Mr. Fellows appeared for the plaintiff; Mr. Kay, Q.C., and Mr. Waller, for the defendant.

JULY 12.

THE GROVER AND BAKER COMPANY *v.* WILSON.

THIS cause came on to be heard before a special jury, but only nine gentlemen were present, and the trial stands postponed till next term.

It involves questions whether the defendant, of the firm of Newton, Wilson, and Co., has not infringed some of the plaintiff's patents for the manufacture of sewing machines.

Mr. Amphlett, Q.C., Mr. Grove, Q.C., and Mr. Lawson appeared for the plaintiffs; Mr. Eddis, Q.C., Mr. Williams, and Mr. Aston for the defendants.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Naval, Military, and Gunnery Items.

A TELEGRAM from Shanghae communicates the sailings of the first tea ships this season for England, namely, the "Titania" and "Huntley Castle" sailing ships, and the "Agamemnon" and "Erl King" steamers. Their cargoes in the aggregate amount to 6,000,000lb. of tea.

ONE of the largest iron ships of war ever yet built has been laid down at Pembroke Dock, and she is to have the name of "Thunderer." A number of heavy armour-plates have arrived to be used in her construction, and when completed it is expected she will be the finest vessel of her class in the British navy.

A GREAT improvement has been effected in breech-loading cartridges, by the Colt Firearms Company, by which the cartridge case can be re-loaded and capped after firing, thus utilizing the same case a number of times. We are obliged to defer the details of this important invention until next week.

THE Emperor of the French has awarded a gold medal of the second class and a diploma to Mr. Peter de la Mare, and a silver medal of the first class and a diploma each to Mr. John de la Mare and Mr. Phillippe le Riche, of St. Heliers, Jersey, in acknowledgment of their services, in January last, to the survivor of the crew of the French lugger, "Villafranca," of Dinan.

THE American yacht "Dauntless," Vice Commodore James G. Bennett, jun., arrived at Queenstown on Sunday, at 2.30 p.m., making the run, from New York to Queenstown, in 12 days 17 hours 6min. 12sec., and beating the time of the "Henrietta" in her famous ocean race with the "Fleetwing" and "Vesta." The "Dauntless" experienced heavy weather the entire voyage.

THE South Holland Institution have awarded a gold medal and a testimonial to Mr. James Herbert, of the barque "T. and R. Walsh," of Queenstown, in acknowledgment of his services to the crew of the Dutch brigantine "Energie," on March 13, 1869. They have also awarded a large silver medal and a testimonial to Mr. John Crawford, of the ship "India," of Glasgow, in acknowledgment of his services to the crew of the "Hollands Trouw," on the July 20, 1868.

THE Emperor of the French has awarded a gold medal of the first class and a diploma to Captain Holker, of the ship "J. R. Hea," of Windsor, Nova Scotia, in acknowledgment of his humane services to the crew, thirty-two in number, of the French ship "Naulonnier," of St. Servan. The Emperor has also awarded a silver medal of the second class and a diploma to Mr. John Woodcock, of the steamer "Tajore," for having rescued a child, who had fallen into the harbour at Marseilles, on August 30, 1868.

THE council of the Institution of Naval Architects, the importance of which is now so far recognized by the Government as to command an annual grant from the public funds, are desirous of receiving special information on the following heads in time for their next annual meeting:—1. Composite shipbuilding. 2. Economy of fuel. 3. The application of steel in lieu of iron to shipbuilding. 4. Iron and steel masts and yards. Practical men in possession of new facts or interesting results relating to any of the foregoing subjects are invited to embody them in papers to be read before the institution, or to forward any results which may have come to their knowledge, to the secretary, at 9, Adelphi-terrace.

WE understand that Mr. Baxter is to be removed from the Admiralty and appointed Secretary for Scotland. Our informant, says the "United Service Gazette," adds, "They don't get on at all well at Whitehall." Just so. It does seem rather significant that from this reforming Admiralty the very first to go is "the greatest Roman of them all"—he to whom was given the task of hunting out and rooting out the very grossest abuses—abuses of such a nature that it is distasteful even to speak of them. From all report, Mr. Baxter was doing his work well. Can it be possible that he was doing it too well, and was got rid of less worse might come of it?

THE last ship built in Woolwich Dockyard was to have been launched, on Monday last, at half-past three. At the appointed time, the ship was duly named the "Thalia" by Mrs. Childers. But she would not stir; neither by persuasion nor by force could the faintest glimmer of hope of her starting be obtained. She was, however, got off at four o'clock on Wednesday morning. The "Thalia" is wood-built, and a sister ship to the "Juno"; she has been designed by the Chief Constructor as a vessel of war and supernumerary troopship. Her dimensions are—length, 200ft. 1in. between perpendiculars; length of keel for tonnage, 171·5⅛; extreme breadth, 40ft. 4in.; breadth for tonnage, 40ft.; breadth moulded, 39ft. 4in.; depth in hold, 21ft. 8in.; burden in tons, 1,459 12-94; horse-power, 400; her armament, 6 guns.

THE Lords of the Admiralty have issued regulations for the issue of prizes and rewards for good shooting to the Royal Marines. The prizes at each division will be three, viz.:—First prize, to the best shot of the division; second prize, to the ten best marksmen of the division; third prize, to the marksmen of the division. The first prize will be £5 and a badge of cross muskets and a crown worked in gold. The second prize will be £3 and a badge of cross muskets worked in gold. The third prize will be £1 10s. and a badge of cross muskets worked in worsted. Whenever the best shot of any division shall have gained a number of points not less than those obtained by the best shot in the army he will be awarded a special prize of £20, a bronze medal inscribed with the year in which won, and the winner's name, company, and division, to be worn on the right breast, and a badge of cross muskets and crown worked in gold. The medal may be worn during the whole period of service. All serjeants having earned the title of marksmen will wear a badge worked in gold.

FROM the Clyde we learn that Messrs. J. and J. Thomson have contracted to supply the engines of four steamers which are being built by Messrs. W. Hamilton and Co., of Port Glasgow, for the Ottoman Government. Messrs. Scott and Co., of Greenock, have launched an iron paddle, named the "Felis Argentine," intended for passenger traffic on the River Plate. The "Felis Argentine" will be engined by the Greenock Foundry Company. The "Oberon," an auxiliary screw, has just left the Clyde for London, where she is loading a cargo for Shanghai. The "Oberon" was built by Messrs. A. and J. Inglis for Messrs. Shaw, Maxton, and Co., of London, and she is expected to make the run out to Shanghai in 75 days. The "Oberon" is 241ft. in length by 36ft. beam, by 21ft. depth. Her burden is 1,235 tons. She is fitted with expansive engines, and can dispense with her propeller when not required, the screw space being enclosed with water-tight shutters, by which means the ship presents one unbroken water line, the propelling space causing no resistance whatever when the vessel is under sail.

Miscellanea.

AT Krenholm, near Narva, in Russia, a number of persons having collected on a bridge, the parapet gave way. Sixty-five were precipitated into the river, and twenty-one were drowned.

WE understand that the Prince of Wales has consented to unveil the statue of Mr. George Peabody, on the site near the Royal Exchange, during the present month. The statue, which is in bronze, is the work of Mr. Story, the American sculptor.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending July 10, was 3,753. Total number since the opening of the Museum, free daily (May 12, 1858), 1,601,535.

A SECOND ascent of Mont Blanc, for the present year, has just been accomplished under favourable conditions by two Englishmen, Messrs. Erdes and Tideman. The number of foreigners who arrived at Chamounix between June 24 and June 30 was 412, making a total for the present season of 1,898.

WE understand that the Commissioners for the Exhibition of 1851 at their last meeting decided to hold a series of annual international exhibitions of select works of fine and industrial art and scientific inventions at Kensington. The first exhibition is fixed for 1871, and as respects industrial works will consist of only three classes.

THE number of visitors to the South Kensington Museum during the week ending July 10, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 13,741; Meyrick and other galleries, 2,928; on Wednesday, Thursday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 2,764; Meyrick and other galleries, 220; total, 19,653. Average of corresponding week in former years, 14,139. Total from opening of Museum, 8,669,729.

ABOUT five o'clock on the afternoon of Wednesday week a smart shock of earthquake was felt in the village of Comrie and neighbourhood. The tremor of the earth was scarcely perceptible, and, as usual, the shock apparently came from the south-west and proceeded to the north-east. Several slight shocks during the night have been felt since, and on all occasions the shocks were accompanied with a noise resembling a railway train or distant thunder. It is a remarkable fact that for a series of years shocks of earthquake have been felt in the month of July, but the strange phenomenon occurs frequently at other seasons.

ON Monday last a meeting of the Yorkshire subscribers to provide a fund to purchase an annuity for Mr. George Hudson, was held at York, the Lord Mayor in the chair. It was stated that the amount of the Yorkshire subscriptions was £1,350. The whole sum realized was £4,400. An annuity for Mr. Hudson could be purchased in the North British office, at the rate of £12 16s. per cent., and £4,000 invested upon these terms would produce £512 per annum. It was accordingly agreed that the subscription be invested in the purchase of an annuity for Mr. Hudson's life, and be so settled that there be no power of anticipation or of assigning the same, or of the amount becoming liable for the demands of other persons.

THE prizes that were offered by Mr. Barkas, of Newcastle, to pit lads, in Durham and Northumberland, to induce them to search for fossil remains, are said to have been attended by the most unexpected results. Not only have the lads picked up from the refuse shale heaps large numbers of fish remains, and some remains of large reptiles, but, what is really extraordinary, and will astonish palæontologists, one of the lads has found the lower jaw of a true mammal. The effect of this discovery will be to reduce the comparative ages of all hitherto known mammalia, and carry back the mammalian life of the world for millions of years.

The "Advertiser and Times," Oswego, N.Y., says, "We saw a novel experiment involving the explosive power of gas. In the new tank excavation, now in a forward state, at the gas works in this city, an old well had been pumped out and then filled up, after leaving an aperture beneath. Into this space a limited quantity of gas was introduced from the gas pipe, sufficient to form an explosive compound with the air in the covered well. A match trigger touched off the mine, when a general upheaving of the surrounding earth took place, loosening up the soil and making easier digging."

THE Royal Horticultural Society's grand show of fruit and flowers, to take place next week at Old Trafford, Manchester, promises to be one of the most magnificent displays ever held. The Queen, as well as the Prince of Wales, will both contribute specimen plants, &c., and there are nearly one thousand entries. The exhibition opens on Monday at three o'clock p.m. On Tuesday, the Duke of Buccleugh, K.G., president of the society, will take the chair at the general meeting. On Wednesday, the Prince of Teck (one of the vice-presidents) will distribute the prize awards, and the grounds will be visited by the Prince and Princess of Wales.

REPORTS from the Sutherland coalfields state that the diggings on Kildonan Burn were deserted last week by a number of the diggers, who, on the expiry of their monthly licence, packed everything up and left for their respective homes. A good many of the men had to leave for the purpose of preparing for the coming herring fishing, but many of the old colonial hands left in consequence of the small yield of gold at the above-mentioned burn and the refusal to extend the ground so as to give them a chance on new claims. At Suisgill, however, many of the diggers continued to make pretty fair earnings, and as soon as their licences ran out a good many went forward and applied for renewals. Small nuggets continue to be found. One was got at Suisgill last week that would weigh 1 1-3oz.

ON Monday week a further discovery, connected with the fine pavement recently found near the Poultry, was made while digging to the south or south-east. A floor of a small ante-chamber of common red tesseræ was exhumed, and a passage way running along the outside of the building, having a concrete floor. Mr. J. E. Price, the indefatigable director of the London and Middlesex Archæological Society, has been carefully watching the excavations for some weeks past for traces of the old Roman Watling-street. Within the last few days this road has been discovered about 10ft. or 11ft. from the present level, the road being about 14ft. wide, formed of a rough gravel laid upon old pottery and other *debris*.

DR. GOUJON has subjected the marrow of bone to a series of experiments, which have yielded startling results. Thus, having extracted some of that matter from the femoral bone of a rabbit, he introduced it under the skin of the same animal, and also into an incision mode in a muscle. After some time he found bony productions adhering to the tissues where the inoculation had been performed. Small cylinders of marrow extracted from the cubitus and radius of fowls were inserted into the pectoral muscles of other gallinaceous species, and in this case also the formation of bone was observed. Hence it follows that the medullary substance contributes towards the regeneration of osseous matter in the same way as the periosteum, and may be engrafted with the same ease as the latter.

THE French iron trade continues active. In the Haute Marne a great demand has been experienced for coke-made iron, and considerable orders have been received for sheets and iron wire. It is proposed to establish a rolling mill on an extensive scale at Marnaval. The production of the Moselle works is rapidly run off, and there are scarcely any stocks. The foundries in the Ardennes are well employed. The orders on hand in Belgium for rails, rolled iron, and plates assure the works continued employment for the remainder of the year. The Belgian construction workshops are still, however, not altogether so active as their proprietors could desire; they have a fair number of orders on hand on home account, but find it extremely difficult to obtain foreign orders, in consequence of the almost prohibitory import duties with which they have to contend.

THE Antiquarian Society of Scotland have just received a donation to their museum of two interesting articles, which cannot fail to be attractive, especially to juvenile visitors and all who have read Defoe's story of "Robinson Crusoe." The relics consist of the sea chest and a carved cocoanut cup, which were the property of Alexander Selkirk, the prototype of Robinson Crusoe. These were with him in his solitary residence on Juan Fernandez, and were brought home with him when taken off the island by Captain Woodes Rogers. They were used by Selkirk while he lived in Largo after his return to his native place. The chest contained his clothes, &c., and when he went off from Largo was left with his descendants, with whom it and the cup remained till the death of one of them a few years ago, when they were sold to a gentleman in London. They were recently placed in the hands of Mr. Chapman, of Hanover-street, for disposal, and have been purchased by Sir David Baxter, who, with his usual generosity, has presented them to the Society of Antiquaries of Scotland.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3906
BUILDINGS AND BUILDING MATERIALS—3873, 3887, 3921
CHEMISTRY AND PHOTOGRAPHY—3914
CULTIVATION OF THE SOIL, including agricultural implements and machines.—3882, 3912
ELECTRICAL APPARATUS.—3878
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3905, 3915
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—3872, 3874, 3875, 3881, 3885, 3889, 3890, 3898, 3901, 3903, 3904, 3918, 3920
GENERAL MACHINERY—3877, 3891, 3894, 3895, 3896, 3897, 3910, 3913
LIGHTING, HEATING, AND VENTILATING—3909, 3917
METALS, including apparatus for their manufacture—3871, 3879, 2893, 3911
MISCELLANEOUS—3870, 3876, 3880, 3884, 3888, 3892, 3900, 3919, 3922
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3886, 3899, 3901
SHIPS AND BOATS, including their fittings—3902, 3916
STEAM ENGINES—3896, 3897
WARFARE—3907

3870 P. SPENCE, Manchester. *Alum.* Dated December 19, 1868.

This relates, first, to the manufacture of alum from shale, the object being to obtain with comparative speed a clear solution of sulphate of alumina which is converted into alum in the usual manner. Second, in operating upon raw or uncalcined shale or indurated clays in a granulated form, for the extraction of iron, and obtaining therefrom sulphate and other compounds of alumina. In carrying out the first part of the invention, the calcined shale now used in the manufacture of alum, according to the mode specified under a patent, dated November 27, 1845 (No. 10970), is taken, but before digesting the shale in sulphuric acid it is ground or otherwise brought into a divided state, so that it will pass through a sieve of eight to twelve meshes per lineal inch, taking care, as far as possible, to avoid the production of dust. This granulated shale is now placed in a lead-lined vessel heated by coils of pipe containing steam of from 25lb. to 40lb. pressure, and add sulphuric acid diluted to about 1·375 specific gravity, and maintain the heat at from 225deg. to 235deg. Fah. In carrying out the improvement in the manufacture of aluminous salts, the shales or indurated clays from the coal measures, or from other sources, is taken, and in selecting these it is preferred to obtain those which contain a large proportion, say from 25 to 35 per cent. of alumina, and which at the same time contain only a small proportion of iron. These shales or indurated clays are taken in their dry and hard condition, not allowing them to be weathered by the atmosphere, and they are brought into granulations that will pass through a sieve of eight to twelve meshes to the lineal inch, and if much fine dust is produced during the grinding, the granulated material is passed over a fine sieve to remove the dust. The granulated substance is now taken and placed in a wooden tank containing, say, from 10 to 20 tons, and cover it with water containing 7½ per cent. of the weight of the granulated material of hydrochloric acid of commerce. After the whole has stood for two days, the solution is run off, and the material washed with water until it is cleansed from the solution, and after draining it is calcined for two or three hours at a low heat of barely visible redness in the dark, and this substance will now be found ready for the extraction of alumina.—Patent completed.

3871 J. JONES, Wolverhampton. *Coating metals.* Dated December 19, 1868.

The inventor constructs a flue of suitable size, made, by preference, of iron, and uses in combination therewith an exhaust fan, worked by steam or other suitable power. In order to obtain a strong draught or current of air upon the top edges of and surrounding the bath, he forms a hollow flat flue of suitable form in section. This hollow flat flue is connected to the main downward draught flue, and is open upon its inner side. Into this hollow flat flue the vapour from the metallic bath is first collected or drawn, by means of the circulation of fresh air, and from thence passes into and is taken down the main flue, being conveyed either to a suitable condenser for the purpose of collecting the metals contained in the vapour, or to an ordinary stack. For some purposes he proposes to employ additional collecting flues above the flat flue already specified, and arranged in suitable positions; and he also purposes to use double-acting fans, or more than one fan, in creating or assisting the desired draught.—Patent completed.

3872 W. S. THOMPSON, Cheapside. *Skirts.* Dated December 19, 1868.

The hoops of the skirt are severally composed of two narrow steel ribbons or flat wires, laid parallel to each other, and at a suitable distance apart (equal, say, to the width of the two ribbons). These are connected together by a lap of cloth, secured and stiffened by paste or other adhesive substance. The hoops, before their ends are joined, are passed through loops in the ordinary suspending tapes, and they are made fast thereto by passing eyelets through the tapes and through the central or cloth portion of the hoops.—Patent abandoned.

3873 J. DICKSON, Leith. *Windows.* Dated December 19, 1868.

The batten rods by which the lower sash is kept in place are provided with a socket. At the upper end of each, and at suitable distances apart, on the inner side, studs with heads are fixed, which pass into corresponding retaining plates fixed to the window frame, so that in putting in the batten rods it is necessary only to slip the upper ends into the sockets and the studs into the retaining plates, after which the batten rods are forced downwards until the mitre on the lower end rests close to the corresponding bottom part of the frame. When so lowered, the batten rods are firmly retained in position, and keep the sash in its place. To remove the batten rods, they are raised sufficiently to enable the retaining heads of the studs to clear the slots in the retaining plates; they are then lifted out, leaving the lower sash free to be lifted out also. The sash lines or chains are connected to the sash by being passed through a metallic or wooden nut, which is of a dovetailed form, and passes into a dovetailed recess in the side of the sash, and thus is easily removed when requisite to detach the sash. The parting beads are fitted into grooves in the frame, by which they are retained in place, and removed when it is required to take out the upper sash, which is connected to or detached from the sash lines by means similar to what is hereinbefore set forth with regard to the lower sash.—Patent completed.

3874 G. H. ASKER, Norwich. *Umbrellas, &c.* Dated December 19, 1868.

In order to confine the outer ends of the ribs to stick when the umbrella, parasol, or sunshade is closed, the inventor employs a cap of ivory or other material surrounding the stick, and fixed in or forming a continuation of the runner, which he calls a "tip cap." The exterior of the cap is inclined, so that the pressure of the ribs against it in closing may cause the cap with the runner on which it is fixed or formed to recede to allow the ribs to enter. To allow the runner thus to move, it is necessary that the runner should be able to slide a distance through the notchpiece upon it, in place of having the notchpiece fixed to the runner, as heretofore.—Patent completed.

3875 T. WARWICK and A. BOYLE, Birmingham. *Umbrellas, &c.* Dated December 19, 1868.

A vertical rack capable of an intermittent descending motion carries the pieces of trough-shaped wires from which the stretchers are to be made. A feeder pushes the pieces of wire one at a time from the rack on to notches on the bed of the machine; or the wires may be fed to the feeder by hand. A carrier worked from the principal shaft of the machine rising takes up the wire, and then advances horizontally until the ends of the wire are brought over the lower dies of two pairs of dies, which operate on the two ends of the wire. The carrier then descending leaves the wire resting by its two ends on the said lower dies. The stretcher wire, before it is put into the rack, has a small strengthening or filling-up piece of cylindrical wire, placed by hand in each end. By the descent of the upper dies upon the lower dies the ends of the stretcher wire are flattened and partially shaped, the filling-up piece giving the necessary strength to the flattened end. On the ascent of the upper or movable dies the carrier again lifts the stretcher wire from the lower dies, on which its ends rest, and carrying it forward places its end on the lower dies of a second set of dies, consisting of two pairs. The invention consists, second, in a machine for testing the stretchers and ribs for umbrellas and parasols, constructed in the following manner:—Two pairs of rollers are mounted on horizontal axes, the upper pair not being immediately over the lower pair, one of the upper rolls being situated midway over the two lower rolls, the other roll of the upper pair being on the same level as the first. By passing the stretchers or ribs between the rolls they are made to take temporarily an undulating or wave-like figure, and, if they are too hard are broken, and if too soft take a permanent set, and in either case are unfit for use. Those that pass through the machine without injury are proper to be made up into umbrellas or parasols.—Patent completed.

3876 W. R. LAKE, Southampton-buildings, Chancery-lane. *Cutting rocks, &c.* (A communication). Dated December 21, 1868.

This relates to a previous patent, dated April 8, 1868 (No. 1183). It consists in the novel construction of the frame of the machine described in the specification of that patent, whereby it is rendered more convenient for supporting and adjusting the drilling mechanism, and in the peculiar means employed in connection with the feeding and rotating devices, also described in the former specification, to prevent the injurious effects upon the machine of the vibration and concussion occasioned by the rapid action of the drill.—Patent completed.

3877 T. R. SHAW, Lancaster. *Lubricators.* Dated December 21, 1868.

This consists of a method of supplying the "steps" or bearings in which the said shafts or journals revolve with lubricating material. On the bottom step or lower portion of each bearing the inventor forms a recess, or he forms the bottom step in two portions, with a space between, or he forms two or more of the recesses, or he forms the bottom step in three or more portions, if found suitable in the case of long bearings. The recess or space on each of the aforesaid recesses or spaces is made of a semi-annular form, or of a form approaching thereto, and is provided with a suitable mouth or orifice through which oil or other lubricant may be poured into the recess, and through which the material can be inserted or withdrawn, the mouth or orifice being, by preference, provided with a lid or cover. On the recess he places a piece of sponge of a suitable form to fill or nearly fill the recess.—Patent abandoned.

3878 W. F. STANLEY, Great Turnstile. *Electrical machines.* Dated December 21, 1868.

This consists, first, in making the framework of an electrical machine to consist of two slips of wood united at the one pair of ends to form a handle, and at the other to form a clamp, thereby obviating the necessity of the stand universally made to every description of rotating electrifying machine. Second, the exciting rubbers are simply attached to the frame instead of having separate carriages and adjustments. Third, the axle is made of wood instead of metal, as in plate glass machines. Fourth, the disc is made of sheet glass instead of being made of plate glass; and, fifth, the collector is formed of a piece of woven wire gauze instead of a comb of metal points.—Patent completed.

3879 R. WILSON, Manchester. *Cutting metals, &c.* Dated December 21, 1868.

The inventor uses two nuts, one of which is constructed so that it can be turned round in its socket when required, and thus made to take up the slack caused by the wearing of the nut or screw. He introduces two or more rests or supports which are connected with each other, and which are made to travel below the screw, and so support it when the nuts are near to either end of the screw. He makes the worm double or in two lengths, having room between the parts for screwing or tightening up when either or both the worm threads or rack teeth or cogs are worn.—Patent completed.

3880 J. E. MASSEY, Chadwell-street, *Sounding machines.* Dated December 21, 1868.

The inventor employs a solid brass frame about 13in. long by 7½in. broad, formed in the shape of an oblong shield, this shape being preferred in order to facilitate its passage through the water. Through the thickness of the frame a hole is formed in the upper part, in which is secured the rope for descent and ascent, and in the lower part another hole through which is secured the rope for attaching the sinking weight. In the upper part of the frame is formed a hollow chamber constructed to receive the registering wheels and other parts of the recording apparatus. The hollow chamber is contrived so as to protect its contents from all pressure of the water, and from being fouled. In this chamber is placed an endless screw and two or more wheels, the first of which gears into the endless screw. The chambers and its contents are covered in by a plate of thick brass, on the other surface of which is a small raised box for the purpose of containing the dial and indices which are protected by a sliding cover formed in the edge of the raised box.—Patent abandoned.

3881 H. G. THOMPSON, New York. *Carpets.* Dated December 21, 1868.

The inventor forms an under or additional shed with such threads, and inserts a wire having a knife or cutter at one end, as well understood in the manufacture of cut pile fabrics, in such shed to be beaten up, a wire being introduced into each successive shed formed by the ornamental or figure warps as they are successively thrown out of the fabric. The wires thus introduced travel a

suitable distance with the fabric, and are then withdrawn successively, at the same time severing from the fabric those threads which formed the shed into which they were introduced, the ends of the threads thrown out of the fabric remaining, and being, to some extent, held between the back of the fabric and those wires which have not been withdrawn. The ends of those threads which are not being woven into the fabric the inventor holds by means of clamping or holding surfaces, so as to press upon and securely hold the ends of such threads at a short distance from the point at which the weft is being beaten up, the pressure of such clamping or holding surface or surfaces being relieved when the fabric is being taken up, so that the ends of those threads which are not being woven into the fabric may not be drawn forward with it.—Patent completed.

3882 W. LEWIS, Shrewsbury. *Ploughs.* Dated December 21, 1868.

This relates, first, to the method of forming or constructing the plough beam, by having the side of the beam to which the land side or frame and coulters are attached made with an angular or semicircular face, for the purpose of giving additional strength to the beam, and also for the purpose of adjusting the coulter and skim coulter to any required angle. Second, to the method of attaching the plough wheels to the beam. Instead of the usual method, the inventor has on the neck of the beam, solidly forged with the beam, a box or oblong slot; on the bottom edges of the box or slot projecting under the beam he has recesses in which the plough wheel shafts are fitted, having a bearing on each edge of the box or slot; to each plough wheel shaft he has a loop or socket bolt, through which the plough wheel shaft passes in the inside of the box or slot. On the top of the box or slot he has a plate or washer of the same form as the box or slot on the outer surface, with holes for the loop or socket bolts to pass through. Thus, by screwing down the bolt nuts on the washer or plate, the plough wheel shafts are securely fixed in a simple and effective way, and the plough wheels may be adjusted to any gauge with ease and certainty.—Patent abandoned.

3883 J. BAGGS, High Holborn. *Iron.* Dated December 21, 1868.

This consists in drawing the waste gases from the tunnel head or upper part of an iron furnace, and after passing the same through or over or in contact with ignited coke or charcoal or carbon in any form, in blowing the mixed or revivified gases into the furnace again, to be again burnt by meeting the ordinary air blast at the temperature of ignition, and so on, time after time *ad infinitum.* —Patent abandoned.

3884 J. S. WALKER, Lancaster. *Cutting coal, &c.* Dated December 21, 1868.

This consists principally in the use or employment for such purpose of a peculiar form of disc cutter, mounted horizontally on a short vertical shaft, and driven by bevel gearing actuated by a compressed air engine. The whole is mounted on a carriage supported on wheels, running on a tramway, and propelled slowly along the face of the coal or mineral by means of worms and worm wheels also actuated by the same or an auxiliary compressed air engine, or in any other suitable manner. The cutter consists principally of a disc or wheel provided with a vertical rim or flange all round its circumference. Inside the rim or flange is cast a circle of bevel teeth projecting upwards from the face of the disc or wheel, but not so high as the edge of the rim or flange above named. The outer edge or periphery of the rim or flange is provided at intervals with snugs or projections between which the teeth or cutters are fixed by means of keys. The teeth are mounted in groups of four or five, following each other, the first being formed with a simple point in the centre, the second two points, and so on, arranged in such manner that each successive cutter acts upon a different part of the groove or channel, and the whole group leaves no part uncut. The face of the cutter is wider than the thickness of the disc or wheel with its rim or flange, so as to afford plenty of room for clearance, and prevent the liability of the cutting disc or wheel becoming jammed or wedged fast in the groove or channel. A semicircular shield of plate iron with a strong rim or flange may be placed so as to project from the side of the frame over the disc or wheel fitting inside the rim, so as to prevent the cuttings of coal or mineral from falling into and choking the teeth of the bevel wheel.—Patent completed.

3885 L. A. W. LUND and E. ASCMAN, London. *Buttons, &c.* Dated December 21, 1868.

The inventors first form the exterior surface of the article of gold, silver, aluminium, or other precious metal, by stamping, pressing, "spinning," or in any other ordinary manner, leaving the edge turned up a suitable distance, and where the articles are either circular or oval, rollers may also be used cut or shaped to the exterior surface of the article. They then deposit the article in a die, which fits the exterior surface, and press into the interior thereof horn, ivory, tortoiseshell, vulcanite, gutta-percha, wood, or other suitable material or compound, in a warm or plastic state, so as to fill up the interior quite solidly, leaving sufficient space when required for a covering or back plate of gold or other metal or alloy, or of ivory, mother of pearl, or other suitable material. They then insert the covering or back plate, and bend or press over it, the rim or edge of the exterior surface, by pressing, burnishing, "spinning," or in any other manner, so as to combine the whole, and form, as it were, one solid piece, thus producing a stronger and cheaper article than those hitherto made. Or they can attach pins, screws, hooks, clasps, or other fastenings, either by soldering or otherwise, and either to the front or back covering plate or to both, and then press them together, while the filling material is in a warm or plastic state, thus forming one solid piece of the whole.—Patent completed.

3886 E. A. COWPER, Westminster. *Velocipedes.* Dated December 21, 1868.

One of the improvements consists in varying the throw of the cranks, by mounting the crank pins on sliding pieces, carried by arms projecting from the axle, and caused to slide when required by means of screws acting lengthways of the slides, which latter are held securely in position by a set screw or a catch. Another improvement consists in jointing the frame or back at or near the middle of its length, and connecting the two parts either by a hinge so arranged that the two parts, each with its respective wheel, will fold up side by side, and thus occupy a comparatively small space, or the two parts may be made to separate from each other for this purpose, and be connected when required by any suitable known form or fastening.—Patent abandoned.

3887 R. WHITAKER, Wolverhampton. *Locks, &c.* Dated December 21, 1868.

The inventor makes the bolt of a segmental form, and free to move on an axis or round its outer edge, in a box, case, or rim, or by a groove and fillet. The bolt proper is provided with projections or arms and sometimes with slots or grooves, which, through the action of key bits, whether the ordinary bits, or jointed bits, or any description of bit at present in use, shoots or throws the bolt. Sometimes a ward or wards is or are formed on the radial arm of the bolt, for the bit to throw the bolt, and in some cases the bit of the key acts on one or more pins on the arm, while the pipe of the key fits over another pin. The fastenings may be modified, so as to be fixed externally or internally, and be used for various purposes. The lever or levers may be guarded by wards and detectors or by any other means now in use.—Patent completed.

3889 J. WILKINSON, Leeds. *Saddle cloths, &c.* Dated December 21, 1868.

This consists in fitting upon opposite sides of an open woven fabric, by preference that known as scum cloth, and then subjecting a length of this material to the process for which letters patent were granted, dated November 13, 1855 (No. 2553), in order to mould the same to repeats of the shape required for converting the material into saddle cloths and nummahs, instead of operating upon pieces of the compound fabric cut to a suitable size to form one given article. The inventor strains a length of the fabric, while saturated with moisture, over a shape equal in length to that of the fabric to be treated, and presenting in profile several repeats of the counterpart of the figure which it is desired to impart to the fabric. The edges of the fabric he holds down with tenter hooks, carried by adjustable bars, and having thus secured the wet fabric, he leaves it to dry. The effect of thus drying the fabric at tension will be to give a permanent set thereto, and when dry the length may be cut up into pieces to form any given number of saddle cloths or nummahs. The edges have then to be trimmed to complete the shaping of the article, after which he finishes them by a line of stitches run in near the edge of any suitable sewing machine and by applying a binding round the edge.—Patent completed.

3890 T. B. HUBBELL, Euston-square. *Bandage.* Dated December 21, 1868.

This consists of an elastic waistband, from which depends a sack for containing some absorbent material. The sack is formed of india-rubber, and a sponge or cotton waste is placed therein. It is connected to the waistband by pendent strips of india-rubber attached by cement to the front and rear ends of the sack.—Patent abandoned.

3891 J. H. JOHNSON, Lincoln's Inn-fields. *Sharpening saws.* (A communication). Dated December 21, 1868.

It is proposed to adapt temporarily by means of bolts or other convenient fastenings, a small frame to a convenient part of the saw frame, such small frame containing the sharpening and finishing or polishing appliance and means for working the same. The saw to be operated is steadied between guides, and the teeth are then successively sharpened by bringing to bear upon them a file made in the form of an endless screw or helix, which is formed on a steel cylinder or boss mounted on the lower end of a revolving spindle, worked by a winch handle and pair of bevel wheels. On rotating the helicoidal file whilst in contact with the saw tooth, its cutting edge will be sharpened, whilst at the same time the tooth last operated upon is being finished or polished by the action of a rotatory polisher, situate beneath this file, and carried by the same spindle.—Patent abandoned.

3892 H. W. HAMMOND, Manchester. *Spring pawl washer.* (A communication). Dated December 31, 1868.

This relates to washers to be used with bolts and nuts, and consists in cutting through a washer of the ordinary shape, so as to prevent taper edges and allow of its being forced from the form of a plane to that of a helix, by which means, when it is placed in front of a nut and screwed so tight as to again assume the form of a plane, the cut edges will act with such force against the nut and the other parts to which it is screwed as to prevent the nut from turning round when violently shaken by railway trains or other means.—Patent completed.

3893 W. E. GEDGE, Wellington-street. *Resinous bitumen.* (A communication). Dated December 21, 1868.

The bitumen, the subject of this invention, is composed of white or liquid resin, otherwise called gallipot, of lampblack, and of sulphur and red sand from the pit or mine, combined in about the following proportions:—For every 100lb. weight of bitumen—sulphur, 37½lb.; gallipot (or, in case of necessity, colophony), 25lb.; lampblack, 12½lb.; sand, 25lb.; total, 100lb. For bitumen to be applied on wood, the quantity of sand may be reduced by about 5lb. weight, and it is preferable that the wood be rough, that is to say, not planed. In preparing the bitumen, the sulphur must first be thoroughly melted in a sheet iron cauldron or an earthenware pot, the gallipot is then added, and when this has almost entirely melted the lampblack is introduced, and, lastly, the sand, and the whole is carefully mixed over a moderate fire. This bitumen may be used in the shape of bricks, or be laid as a coating upon any desired foundation. It is suitable for bottoms of reservoirs, for pavements of streets or terraces, for roofing, and other applications too varied for enumeration.—Patent completed.

3894 P. G. JARRE, Paris. *Hydro-pneumatic pump.* Dated December 21, 1868.

The object is to provide a means of employing any given motive power for drawing liquid from a spot which may be far from the motor, and of conducting it automatically wherever desired. The liquid is drawn from the place where it is found and forced to the place where it is required, without the use of a single apparatus which cannot be easily inspected and repaired. Near the selected motor an ordinary air pump is placed, the piston of which sucks and forces air. Two pipes, the one conducting the drawn or sucked and the other the forced or compressed air, passes from this pump to the place from which this liquid is to be taken. A little above the level of this liquid is a reservoir communicating by a pipe with the liquid to be drawn, and by another pipe with the spot to which it is to be conducted. Each of these pipes is furnished with an ordinary clack valve, working so that the liquor sucked in to the reservoir cannot return, and that the liquids forced from the reservoir cannot come back into it. The lid of this reservoir carries two apparatuses—the distributor and the float. The distributor is composed of two cylindrical pipes, the axis of each meeting at right angles. This combination of pipes may be dismounted in two pieces, it being cut by a plane passing through the two axes. Each piece has two circular flanges or thimbles to receive the valve chambers. On the side by which the compressed air arrives a valve plays between two seats, so as to cause the forced or compressed air to communicate either with the reservoir or the outer air. On the right, two valves, fixed on the same axle, play in such a manner that when the one is open the other is closed, and thus cause the suction to communicate either with the outer air or with the reservoir. The axles of the valves are linked to a vertical rod, by means of two small connecting rods, the axles being guided by the actual seats of the valve. Supposing the rod to be moved by an impulsion, acting from below upwards, the compressed air will communicate with the reservoir, and the suction with the atmosphere. If, on the contrary, the rod receives an impulsion, acting from above downwards, it will pull the two axles, and the compressed air will communicate with the atmosphere, and the suction with the reservoir.—Patent completed.

3895 W. E. GEDGE, Wellington-street, Strand. *Cocks* (A communication). Dated December 21, 1868.

This cock may be termed an every pressure cock, for its exterior may assume any of the usual forms, and it may discharge the liquid from beneath, or by a bent or a straight spout. It may also be a three-way cock, and be made of any kind of metal, and of all sizes. The interior arrangement of this cock consists of a metal lid or cap, pierced for the passage of the stem or plug, which governs the movement and screwed on the box, either interiorly or exteriorly, a washer of leather, india rubber, gutta-percha, or any other malleable and impervious material, seized by the inner or outer screw of the cap, and also permitting the passage of the stem or plug governing the movement, and to which is fitted indifferently a key, handle, or spanner, of any desired form. This stem passes through the metal cap and leather washer, and carries, so as to form one piece with it, an inner disc of metal coming on to a leather washer situated above it, and acting as an obturator. There is another stem or plug, independent of the first, but governed by it in the circular movement by the aid of a mortice which unites them at a certain point. This stem, like the upper one, has a metal disc of one piece with it and bearing upon a second washer of leather, india-rubber, or analagous material, which washer rests upon another disc, supporting the entire arrangement, and forming part of the cock, being cast with or brazed to it. This second leather washer is kept in place and prevented from following the circular movement by a ring or other means. A helical spring is placed between the two metal discs, tending to press them on the two leather washers above and below them. The axis and washer are pierced with two openings passing through all three in a direct line. These openings may, according to the description of cock, be four in number, or there may be but a single one; it is only requisite that the disc should be able to close them, as will now be explained. The water arriving by the barrel fills the box or chamber of the cock, and by its pressure pushes the two metal discs against the two leather washers, perfectly closing the chamber top and bottom. The helical spring is intended to assist this water power should its pressure be insufficient, and it may therefore be used or dispensed with according to requirement.—Patent completed.

3896 J. BREEDEN, Birmingham. *Valves.* Dated December 18, 1868.

The body of the tap or valve consists of a chamber, in which a conical valve seat having its greatest diameter downwards is formed. The lower division of the body of the tap communicates with the ingress pipe, and the upper division with the egress pipe. Working on the valve seat is a conical valve opening downwards. The spindle of the conical valve works in a tube on the bottom of the lower division of the body of the tap, and a coiled spring on the spindle raises the valve, and keeps it to its bearing on the conical seat described. The pressure of the liquid steam or gas also tends to raise the valve and press it on its seat. In the top of the body of the tap is an opening from which a tube depends. The tube is screwed within, and a screw rod with a hand wheel or other handle at the top rises and falls by a rotary motion in the said tube. When the handle is so turned as to depress the rod its lower end presses upon and depresses the valve, and a communication is thereby opened between the ingress and egress pipes. By reversing the motion of the handle the valve no longer pressed from its seat is raised thereto by the spring, and the communication between the ingress and egress pipes is closed. The motion of the screwed rod and valve downwards is limited by the spindle of the valve, and the motion of the said rod upwards is limited by its enlarged lower end coming against the lower edge of the screwed tube. The valve is guided in its motion by three or other number of upright guides, situated near its periphery, working in a short tube surmounting the valve seat.—Patent completed

3897 J. CLAYTON, Lancashire. *Valves.* Dated December 21, 1868.

On an axis, the partial rotation of which opens and closes the valve, a disc, having clutch teeth upon its face, is mounted in such manner that it can move longitudinally upon axis, but when it turns it carries the axis and valve with it. On this disc is an arm which by a rod is connected with the spring for closing the valve. Behind the disc is a spring tending to move it along the axis, pressing it constantly against another disc, which, by the action of the eccentric, is caused to rock to and fro around the same axis. This disc has recesses in it corresponding with the teeth of the first disc, and when these teeth and recesses are opposite to each other they lock the one into the other, and then the two discs move together, and the eccentric is so for the time coupled with the axis and the valve is opened. When the valve is to be again closed the discs are separated the one from the other, until the teeth are withdrawn from the recesses, and immediately the spring closes the valve. The separation of the discs is effected by means of inclined or cam surfaces on the first disc, which abut on an adjustable surface having other inclines upon it, and when, by the motion of the disc, the inclines meet, the disc is pushed back and disengaged from the eccentric, as already described.—Patent abandoned.

3898 G. RITCHIE, Folkestone. *Parasols, &c.* Dated December 21, 1868.

The inventor connects the outer ends of the stretchers

to the ribs by forming a bead or enlargement on the end of each stretcher to enter a groove formed longitudinally along the rib. The stretchers are at their inner ends jointed to a runner, but are made much shorter than heretofore usual. When the runner is moved upwards along the stick, the outer ends of the stretchers slide along the grooves in the ribs, and as the runner approaches the point at which the ribs are jointed to the stick, the stretchers force the ribs outwards to cause them to stand out at right angles, or nearly so, to the stick, and, similarly, if the runner is drawn downwards, they will draw the ribs inwards towards the stick. The grooves in the ribs are narrowest at the mouth, so that the projections on the ends of the stretchers cannot be drawn outwards from the grooves. The runner may be prevented from turning around the stick by a pin or stop on the runner working in a groove or slot in the stick, or in place of the stretchers being jointed to a runner and sliding in grooves in the ribs, they might be jointed to the ribs and slide in undercut grooves or slots in the stick. In this case, the inner ends of the stretchers would, in opening the parasol, be all simultaneously pressed upwards by a runner being moved along the stick, so causing a disc on the end of the runner to bear against the ends of the stretchers. When the parasol is opened, the runner is stopped from moving further along the stick by a stop, and the ribs near to where they are jointed to the stick, and at the same time be forced upwards by the stretchers against a disc carried by a ferrule fixed to the stick, and the ribs are thus held firmly. A cord is sewn on to the outer silk covering near its outer edge, to give strength, and prevent the parasol being blown inside out by the wind.—Patent completed.

3899 W. R. CLARK, Forest Hill. *Signalling in trains.* (A communication). Dated December 21, 1868.

The inventor places in the guard's van, and on the engine, a small signal lantern, the glass of which is ordinarily covered over by a screen, which is held in position in front of the glass by a small detent or stop, but when an alarm is to be given the detent or stop is caused to be withdrawn from in front of the screen, and the screen is then, by a spring, turned down on a hinge at its lower end, and so the light is uncovered and the alarm given. A continuous tube is fitted along the tops of all the carriages, and when the alarm is to be given the air in this tube is compressed, and by this means small plungers working in cylinders connected to its ends will be forced outwards, and caused to release the stop by which the screen is retained.—Patent abandoned.

3900 H. T. VANNER and E. BREST, Great St. Helen's. *Leather.* (A communication). Dated December 21, 1868.

Heretofore, in currying and dressing leather, it has been usual to employ neat's foot oil or cod or fish oil together with tallow. According to this invention, the residuum oil obtained when distilling petroleum is employed for this purpose. When the residuum oil is of a specific gravity of about 880, which is about the specific gravity of the oil as now usually manufactured, it is preferred to use it with tallow in the proportion of 14lb. of oil to 16lb. tallow.—Patent completed.

3901 L. J. PAINE, Oxford-street. *Combined collar and comforter.* Dated December 22, 1868.

This consists in a new or improved removable collar, or collar and comforter combined, for attaching above the ordinary fold-down collar of great coats, coats, waistcoats, jackets, cloaks, and other upper garments made of fur, velvets, cloth, imitation fur cloth, or any other suitable or fashionable material worn for comfort or elegance round the neck. One arrangement of this invention consists in making a collar of fur or other material of similar shape, but a little larger than the collar over which it is to be worn, and fitting a long thin hook at each end and another similar hook at the back, and having small holes made in the ordinary collar of the coat into which these hooks can be placed, thus making a double or second collar which can be easily attached or detached, and when required as a comforter the collar may be turned up round the neck of the wearer with the fur inside, so that both collars would then form a most comfortable and close-fitting cravat or muffler.—Patent abandoned.

3902 J. JENSEN, Christiana, Norway. *Reefing and unreefing.* Dated December 22, 1868.

The mainsail is to be rolled upon a boom on which the foot rope of the sail is fastened. The boom is to be placed over the main boom in two davits which are fastened on each end of the main boom where the reef boom turns. At the fore end of the reef boom is a wheel where the one end of the reef line is made fast and turned up; the other end is fastened to a windlass placed on the deck underneath the wheel and the main boom. On the middle of the reef boom one end of a piece of sennet is fastened, and the other end is put through a buckle-formed hook which grabs round the reef boom. A piece of parsling is served on the sack whereon the rollers belonging to the mast hoops revolve, when reefing or unreefing the sails. On the fore side of the reef wheel there is a comb wheel pawl. The uppermost hoop is fastened to the claw of the gaff at a proper distance from the gaff, and the other mast hoops are fastened to each other at proper distances. A line is fastened to the lowermost loop and again made fast to the masthead through a block, and so passes down to the deck. The main boom rests as usual on the collar of the mast, the boomlifts and sheet also as usual. The gaff is furnished with a claw and peakhalyard.—Patent abandoned.

3903 M. CHALLINER, Grimesthorpe. *Forks or spoons.* Dated December 22, 1868.

For the formation of forks with handles, the steel, iron, or other metal is first rolled into square rods of different thicknesses, according to the sizes of the forks required. The rods are then forged into what in the trade are called moods. These moods are then placed in prints to form the shanks and bolsters; after having been formed or shaped in the prints they are placed in dies, including prongs, shanks, and bolsters, of any pattern or design, and stamped. This is done to secure uniformity in the length of the shanks. The guard holes for carvers and cook forks are stamped at the same time instead of the ordinary method.—Patent abandoned.

3904 J. PALMER, Sutton Coldfield. *Forks.* Dated December 22, 1868.

This consists in manufacturing the forks by making the fork moulds from which the forks are made by the process of casting. The inventor makes patterns of the shape of the required fork moulds, and he either makes the casting moulds from the said patterns in sand or he makes metal or chill casting moulds therefrom in the ordinary manner, and he casts melted steel in the said casting moulds, so as to produce the said fork moulds. He finishes the forks from the fork moulds, made out of cast steel, by forging and drawing out the same, and attaching the langet thereto in the ordinary manner. Or the part to form the langet may be cast in one piece with the fork mould.—Patent completed.

3905 S. TIDCOMBE, Watford. *Paper-making machinery.* Dated December 22, 1868.

The object is, first, to facilitate the rapid feeding of the paper from paper-making machinery, or from other supply, to cutting means, in order to increase the rapidity of the cutting of it into sheets, and also when the paper is cut from long lengths into sheets to facilitate the collecting of the sheets as cut. In carrying out this part of the invention, the paper, as it passes from a paper-making machine or other supply, in place of passing to the action of one set of knives, passes between guides to conduct the paper to one and then other set of knives and similar guides, aided, when necessary, by belts or aprons, which are used to conduct the separate sheets in succession, as they are cut alternately or otherwise to lay boards, placed in opposite inclined directions or otherwise, as may be most convenient, or into other suitable receivers, to be taken by the collectors, by which an additional number of collectors may be employed. Or, in place of the hands now employed for collecting such sheets, atmospheric pressure and vacuum is used for this purpose. As each sheet is cut it passes over a box, the sides of which are perforated, and these perforations are in connection with an air pump or other means of producing a vacuum, so that as each sheet passes over the box it is drawn therein at each stroke of the knife, and as it becomes laid it forms a new button, and as the box fills the sheets can be withdrawn in packs from beneath the other, and the cutting and filling go on at the same moment. The improvements relate, secondly, to means for use in damping paper, in order especially to facilitate printing thereon. The paper to be damped is conducted into a chamber formed for this process, so as to prevent as much as possible the escape of the steam or fine spray of water admitted therein by suitable pipes. The paper to be damped is conducted by felt or other suitable sheet conductors to between two pairs of rollers, and the surface between the separate pairs of rollers is enclosed by plates, with edges bearing against their surfaces; the ends are also closed, thus forming a closed box or chamber. Other rollers also aid in conducting the sheets. Perforated pipes conduct the steam or fine jets of water into the chamber thus formed to act on the paper as it passes through it. One pair of the rollers may be heated by steam to dry the felt or other conductor after saturation; water of condensation may be drawn off by a tap or self-acting valve.—Patent completed.

3906 J. H. JOHNSON, Lincoln's Inn. *Pulleys.* (A communication). Dated December 22, 1868.

The wooden pulley being ready to receive the metal covering, a disc of the required diameter is cut out of sheet copper by any well known cutting apparatus, but it is preferred to employ a cutter, acting on the principle of a pair of shears, which are to be attached to the end of a lever. The metallic sheet is guided to the proper height and then pinched between two holding surfaces, whilst the cutters detach the disc, which falls the moment the holders are separated. In lieu of cutting discs from a flat sheet-rings of the proper width may be cut from a drawn tube made without weld. The disc above referred to is then submitted to a stamper, which turns up the edges, two holders nipping the edges until the stamper enters, whereby the folds or corrugations are prevented from forming on the turned-up edges. The metal covering is then applied to the pulley, and is forced into the groove and over the face by pressure applied thereto by the successive action of two pulleys, one of which forces the metal down into the groove of the pulley, and the other folds over and presses down the protruding metal against the face or side of the pulley. All excess of metal is then cut away by two tools acting simultaneously upon the two faces of the pulley, and tending, at the same time, slightly to imbed the metal into the wood. A forked piece detaches the pulley from the rotatory mandril upon which it is mounted when under the action of the pressing pulleys and cutting tools.—Patent completed.

3907 F. G. GISBORNE, West Strand. *Torpedoes.* Dated December 22, 1868.

The inventor encloses wi or attaches to the shell of the torpedo or other explosive charge a compound needle, which is mounted upon a pivot or centre of motion, and is suitably counterbalanced, so as to keep the point thereof away from a suitable contact piece; also in connection with the shell of the torpedo or other explosive charge. The needle is placed in metallic contact with one pole, whilst the contact piece is in metallic contact with the other pole of a suitable battery or other electrical machine, carried by the shell of the torpedo or other explosive charge, or placed at any suitable distance therefrom, and connected thereto by means of a conducting wire.—Patent abandoned.

3908 S. SMART, Bromley. *Boilers.* Dated December 22, 1868.

This relates, first, to improvements in longitudinal multitubular boilers, in the furnaces of which one or more horizontal water tubes are suspended, closed at both ends, and of such diameter as to enable the inventor to insert into them from end to end a number of fire tubes communicating at one end with the furnace of the boiler, and at the other end with a smokebox at the firing end of the boiler. A number of fire tubes pass from this smokebox through the water space of the boiler into another smokebox at the opposite end of the boiler, communicating with the chimney, and the hot gases are thus caused first to play around the suspended horizontal water tubes, and then to pass from the furnace through the suspended horizontal water tubes into the front smokebox, and thence through the second series of fire tubes into the chimney. The horizontal water tubes are held suspended in the furnace by means of short water tubes forming communications between the horizontal water tubes and the boiler at the upper and lower ends of the firebox. Each of the horizontal water tubes is fitted with one or more mud holes, for the purpose of cleaning them internally when required. The upper part of the furnace is made of increased strength, into which is fastened a series of chain tubes, into which are inserted inner tubes, hereinafter described.—Patent completed.

3909 F. G. GISBORNE, West Strand. *Gas.* Dated December 22, 1868.

The inventor employs apparatus consisting of a cylinder, which is provided with two chambers at its lower part; into the lower chamber is admitted air, and into the upper one gas. From the top of the lower chamber rise pipes or tubes, which pass up to or through the top of the gas chamber, a suitable annular space being formed around each of such tubes in the cover of the gas chamber. A combustion chamber is formed above the gas chamber and a boiler above the combustion chamber, through which boiler pass suitable tubes to carry off the products of combustion, and such tubes rise up a certain distance above the water level, and immediately above such tubes are fixed one or more retorts.—Patent abandoned.

3910 J. SNAPE, South Wales. *Pumps.* Dated December 22, 1868.

This consists in the employment of two drums, one of which is formed with six or other convenient number of convex surfaces, and the other with corresponding concave surfaces. These two drums revolve in opposite directions, and in their revolution the convex portions of one fit into the concave portions of the other. These drums, when applied to ventilating mines, are fitted at the upper end of the air shaft, and their respective convex and concave portions in their revolution move round in segments of circles. In the revolution of the convex drum, air from the shaft is drawn into the space between each successive pair of convex surfaces, and is carried off in this space round the segment until it reaches the open air; in the revolution of the concave drum air is in like manner drawn into each successive concave or recess, and carried off in the same manner.—Patent completed.

3911 D. S. PRICE, Westminster. *Iron.* Dated December 22, 1868.

The inventor uses either the alkaline metals or such of the oxides and carbonates of the same as are suitable for the purpose, or salts thereof, which, on combustion, yield carbonates, and some of the chlorides or mixtures of the above-named metals, oxides, and salts. When using the metals, he passes them by suitable known means into the molten mass of iron.—Patent abandoned.

3912 A. LEZILLE, Paris. *Corn.* Dated December 22, 1868.

The improved process consists of the following operations:—First operation.—The grain is thrown into a receptacle filled with water, and is stirred about therein for some minutes, when any defective grain will float on the top of the water, and can readily be removed. The washing has also for its object to remove dust and other impurities. After the grain has been steeped in the water for about half an hour, the water (which will be found quite turbid even with the best grain) is run off. In place of steeping the grain, it may also be merely subjected to the action of jets of water. By this first operation the pellicle of the grain is distended. Second operation.—The grain thus moistened is passed through a sheet metal cylinder or tube having a rasp-like inner surface, whereby the outer coarser pellicle of the grain is removed. The second pellicle, beneath which is the colouring matter, is removed by passing through a horizontal sheet metal cylinder with rasp-like inner surface, inside which are among stiff brushes, which act on the grain and render it as white as rice. Third operation.—This operation consists in steeping the grain, after removal of the pellicle, in a vessel filled with fermenting liquor, prepared as hereafter described at a temperature of from 68deg. to 77deg. Fah. and in the proportion of about 200lb. of liquor to about 100lb. of grain, in order that the latter may be well covered with the water. The grain is introduced after the liquor has been prepared, about from eighteen to twenty-four hours, in order that this may have attained its full energy. The grain is subjected to the action of the liquor for about seven or eight hours, during which time the fermentable matter in the liquor acts by degrees on the grain, penetrating into it gradually and extracting to a great extent the colouring matter situated beneath the skin of the grain; the liquor, which becomes of a reddish tinge, is then drawn off. The fermenting liquor is prepared by mixing with water at a temperature of from 68deg. to 77deg. Fah., about ten per cent. of fermented dough. Fourth operation.—The grain is then drained, and is placed in a hopper, which, by means of a distributer, causes it to pass between one or more pairs of revolving cylinders, which reduce it to paste as it passes through. This being completed, the requisite quantity of salt is dissolved in water, and is then poured on the dough placed in a kneading trough. The dough is then kneaded so as to thoroughly mix all the particles thereof, and the operation of making bread is completed in the usual manner, that is to say, the dough is divided into loaves, turned, left for completion of the fermentation, and at the desired moment is placed into the oven, yielding a very white and nourishing bread.—Patent completed.

3913 W. CLAY, Liverpool. *Forgings.* Dated December 22, 1868.

The inventor proposes, when forming heads, collars, or flanges upon the ends of shafts or rods, to employ a horizontal hammer of peculiar construction, which is connected with and operated by a piston working in a horizontal steam cylinder, and thereby materially to reduce the sectional thickness of the metal at the line of junction of the head, collar, or flange with the shaft.—Patent completed.

3914 J. S. JENNINGS, Lambeth. *Sewage.* Dated December 22, 1868.

The inventor employs a hollow rotating screen of conical or other form, into the interior of which the sewage is directed. The sewage, in entering the screen, is made to act on a waterwheel or on float boards or similar instruments on its axis, and so the screen is rotated. The sewage enters the screen at one of its ends, and runs through its sides and is received into a trough below, whilst the stones and solid matters are discharged at the opposite end of the screen into a cart or other receptacle. In driving the screen as above described by a waterwheel, acted upon by the sewage before it enters the screen, the power for driving the screen might be obtained by causing the sewage, as it flows away after passing through the screen, to drive a waterwheel, or the screen may be driven by other power. In some cases, the inventor employs a screen formed by joining together a number of bars, so as to form an endless straining surface. This endless surface is passed around rollers, and held distended between them. The sewage is let on to the surface as it slowly travels around the rollers. The liquid flows through and is received into a trough on the other side, whilst the solid matters are carried along and dis-

charged over the roller as the bars pass around it. The passage over the rollers tends to free the straining surface from obstructions.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated July 6, 1868.

2028 G. Buchanan, Surrey-street, Strand. Improvements in preserving animal and vegetable substances for use as food.

2029 W. B. Haigh, Oldham, Lancashire. Improvements in machinery or apparatus for cutting, sawing, and boring wood.

2030 J. Gedge, Wellington-street, Strand. An arm and reclining chair for travellers.

2031 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in apparatus or machinery for composing and distributing type.

2032 W. Walker, Dundee. Improvements in motive-power engines, rotary pumps, and fans.

2033 W. L. Wise, Chandos Chambers, Adelphi, Westminster. Improvements in apparatus for lubricating the cylinders of steam engines.

2034 C. Crockford, Amlwch, Anglesey. Improvements in the mode of treating the ores of lead or products containing lead, either isolated or in combination with other metals or minerals for the purpose of producing metallic lead and other metals and their compounds, and also in furnaces for carrying out the said operations.

2035 C. E. Brooman, Fleet-street, City, patent agent. Improvements in apparatus for heating and distilling water for boiler and other purposes.

2036 L. and L. Clayton and J. Smith, Hunslet, near Leeds. Improvements in the construction of taps or valves.

2037 W. Bray, Stockton, New Jersey, U.S.A. Improvements in refrigerators, more especially designed for railway provision carriages.

2038 W. Q. East, Drummond Hotel, Drummond-street, Euston-square, Middlesex. Improvements in the means of, and apparatus for, indicating or registering the flow of liquids or fluids from vats, casks, or other receptacles.

2039 W. Pidding, Walcot-square, Lambeth, Surrey. Improvements in the mode or modes of obtaining scents, aroma, perfume, or essential oils from flowers, and from all vegetable substances producing the same, also in the machinery or apparatus in connection therewith.

Dated July 7, 1869.

2040 J. Shore, Rochdale, Lancashire. Improvements in cards used in carding engines and other similar machinery.

2041 D. Cope, Liverpool. Improvements in apparatus to prevent waste of liquids in filling casks.

2042 H. E. Knight, Love-lane, Wood-street, City. Improvements in the construction of busks for stays, bodices, gaiters, and other articles of wearing apparel.

2043 F. Walton, Staines, Middlesex. Improvements in scrapers for removing mud from boots and shoes whilst in wear.

2044 J. B. Rogers, Hastings, Sussex. Improvements in velocipedes, motive apparatus, and wheels for the same and for other uses.

2045 V. A. Deaubeuf, Maindy, near Cardiff, Glamorganshire. Improvements in machinery or apparatus for compressing and moulding small coal and other matter or material for which great pressure is required.

2046 A. P. Price, Lincoln's Inn-fields. Improvements in producing partial or complete anæsthesia.

2047 R. Mallett, Victoria-street, Westminster. Improvements in the manufacture of iron and steel, parts of such improvements being applicable to other metallurgical purposes.

2048 F. Trappes, Ely-place, City. Improvements in the construction of velocipedes.

2049 J. Robinson, Rochdale, Lancashire. Improvements in machinery for cutting dovetails.

2050 W. E. Newton, Chancery-lane. Improvements in converting or puddling furnaces for decarbonizing iron.

2051 W. Arnold, Barnsley, Yorkshire, and W. Carnelley, Fallowfield, near Manchester. Improvements applicable to steam boilers.

2052 A. V. Newton, Chancery-lane. Improvements in the construction of chandeliers.

2053 W. R. Lake, Southampton-buildings, Chancery-lane. An improved method of, and means for, removing artificial coatings from metallic surfaces.

2054 J. H. Johnson, Lincoln's Inn-fields. Improvements in the preparation of meat for preservation, and in the preservation of the same.

2055 B. P. Faucheux, Poultry, City. Improvements in boxes or holders for matches and other articles.

Dated July 8, 1869.

2056 C. S. Berthon, Margaret-street, Cavendish-square, Middlesex. Improvements in squares for finding the centre of circles and marking the outlines of regular or irregular figures thereon.

2057 J. G. Rollins, Old Swan Wharf, Upper Thames-street, City. Improvements in reaping and mowing machines.

2058 J. Wright, Moorgate-srreet, City. An improved shaving mug.

2059 W. Davis, Merthyr Tydvil, Glamorganshire. An mprovement in the treatment of tallow used in the manufacture of candles and soap.

2060 T. Knowles, Birmingham. Improvements in wrought-iron permanent way for railways.

2061 L. Williams and R. C. H. Wallendahl, Birmingham. Improvements in machinery for the manufacture of fish hooks.

2062 I. L. Pulvermacher, Regent-street. Improvements in the construction of chains, batteries, and apparatus for producing electric currents, also in means of applying the same for medical and other purposes.

Dated July 9, 1869.

2063 W. Hutchinson, Regent-road, Salford, Lancashire. Improvements in machinery and apparatus employed in the manufacture of bricks and other articles of clay.

2064 H. H. Murdoch, Staple Inn, Middlesex. Improvements in means or apparatus for propelling canal boats and other vessels.

2065 T. James, Liverpool. Improvements in sewing machines.

2066 F. Baker, Kennington, Surrey. Improvements in means and apparatus for opening, closing, and securing railway level crossing and other gates.

2067 J. H. Jones, Field-terrace, New Wandsworth. Improvements in lamps.

2068 M. A. Muir and J. M'Ilwham, Glasgow. Improvements in looms for weaving.

2069 J. Aitken, Lasswade, near Edinburgh. Improvements in obtaining motive power.

2070 G. A. Nowell, Nuneaton, Warwickshire. Improvements in lamps.

2071 F. J. Manceaux, Paris. Improvements in breech-loading firearms, and in cartridges for the same.

2072 W. Allan and P. D. Nichol, Sunderland Engine Works, South Dock, Sunderland. Improvements in steam generators or boilers for marine purposes.

Dated July 10, 1869.

2073 A. M. Clark, Chancery-lane. An improved mode of measuring or dividing time applicable to chronometers, sextants, and other such like instruments.

2074 J. W. Jackson, Windsor-street, Brighton, Sussex. Breakwaters, sea defence walls or entrances for docks, and docks.

2075 J. Walker, Mansell-street, Aldgate, Middlesex, and P. A. Godefroy, Templer-road, Homerton, Middlesex. The manufacture of new or improved dyes or colouring matter.

2076 C. E. Brooman, Fleet-street, City, patent agent. Improvements in central-fire cartridges, and in apparatus for extracting the same.

2077 J. Gessert, Manchester. Improvements in the recovery of nitric acid in the manufacture of sulphuric acid, and in apparatus connected therewith.

2078 T. Kendrick, Birmingham. Improvements in certain descriptions of knobs for bedsteads, door handles, and other similar purposes.

2079 T. D. Waller, Palace-square, Norwood, Surrey. A self-acting measuring and tilting cask stand.

2080 C. L. Caldesi, Grosvenor-street, Grosvenor-square, Middlesex. A new or improved kitchen cart to be used for military and other purposes.

2081 J. Beard, Droylsden, Lancashire. Improvements in pumps.

2082 S. Read, Buchanan-street, Glasgow. Improvements in finishing fibrous and textile fabrics, and in the machinery or apparatus employed therefor.

2083 J. S. Crosland, Manchester. Improvements in, or applicable to, marine and stationary steam engines, boilers, and furnaces.

2084 J. B. Couper, jun., Dunfermline, Fifeshire. Improvements in horse shoes.

2085 J. Bannehr, Great Queen-street, Westminster, and H. Matthews, Gower-street, Middlesex. Improvements in means or apparatus for drying, airing, and warming woven fabrics, bottles, and other articles, and for indicating the presence of moisture therein, and in bedding.

2086 J. Worth, Church Stile, Rochdale, and W. Turner, Tonacliffe, near Rochdale. Improvements in cards for carding cotton, wool, and other fibrous substances.

2067 W. R. Lake, Southampton-buildings, Chancery-lane. An improved method of producing marquetry and other divers coloured woodwork.

2088 W. R. Lake, Southampton-buildings, Chancery-lane. An improved machine for manufacturing horse shoes.

2089 W. R. Lake, Southampton-buildings, Chancery-lane. An improved safe bedstead.

2090 W. R. Lake, Southampton-buildings, Chancery-lane. An improved machine for sawing, grooving, moulding, dovetailing, and otherwise working wood.

Dated July 12, 1869.

2091 Q. Dunlop and T. J. Martin, Ballymacarrett, Downshire, and W. Orr, Ligoniel, Antrim. Improvements in couplings and wheels for shafting and gearing.

2092 J. Dewar, Kirkcaldy, Fifeshire. Improvements in treating certain substances for food and for manure.

2093 C. A. Bates, George-street, Blackfriars-road, Surrey. Improvements in apparatus to be applied to the mouths or openings of letter boxes to prevent letters being stolen therefrom.

2094 E. Sutton, Regent-street. Improvements applicable to speaking pipes.

2095 L. Schalleidner, Rue de Malte, Paris. Improvements in the engine to stamp the waxlights.

2096 W. Bayliss, Cannon-street, City. Improvements in iron vermin-proof rick stands.

2097 J. Henderson, Leith, Mid Lothian. Improvements in surface condensers and refrigerators.

2098 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in apparatus for cleansing grain, more particularly applicable to flour mills.

2099 O. Mertens, Barge-yard, Bucklersbury, City. An improved construction of cartridge box.

2100 E. Pettitt, Manchester. Improvements in machinery for preparing and spinning cotton and other fibrous substances.

2101 J. H. Player, Birmingham. Improvements in utilizing the residual sulphate of lime produced in the manufacture of phosphorus.

2102 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in the manufacture of white lead.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, JULY 23, 1869.

THE ROYAL AGRICULTURAL SOCIETY'S SHOW AT MANCHESTER.

WE last week indicated the character and extent of the Royal Agricultural Society's Show at Manchester, which proves itself to be one of the most successful ever held. Last week was occupied by several sets of judges in testing the reaping and mowing machines, and plenty of work they had to do, the exhibits, in this respect, being unusually numerous. It would be utterly impossible for us to describe one-tenth part of these machines and implements; suffice it, therefore, to say that our tried and well-known makers maintained their reputation, whilst among new comers merit was not wanting, although some failures will have to be recorded by the judges. Following our usual course, we shall take our readers with us through the entire show, but we will not ask them to examine with us the 8,000 exhibits. We shall save them that trouble by selecting such machines and implements as are interesting to them, at the same time premising that if we do scant justice to some exhibits and omit others, it is simply from the fact that it is impossible to crowd everything into our limited space. We shall, however, endeavour to do justice to all by describing the leading exhibits of the show. We shall give a special list of the prizes in due course.

To begin at the beginning, we will take Stand No. 1—that of our old friends Messrs. Barrows and Stewart, of Banbury—although we shall not continue our numerical consecutiveness very long, the busy pressing throng forbidding our visiting each stand in rotation. Messrs. Barrows and Stewart exhibit some excellent samples of their well-made steam ploughing and thrashing machinery, consisting of one 12-horse double cylinder and one 8-horse single cylinder portable engines, two combined thrashing and finishing machines, cultivator, anchor, snatch block, rope porters, &c. The arrangement of the boilers, cylinders, &c., of these engines is such as must secure unusual strength, the greatest amount of steam space (the steam being taken from the quietest position in the boiler), and the smallest possible consumption of fuel; while the strength and simplicity of the working parts renders their management most easy—advantages which every farmer will appreciate. The thrashing machines present a variety of improvements and advantages. One has the patent wind elevator, two shaker cranks, one at each end of the shakers, and Penney's adjustable rotary corn screen, which is fixed at the end of the machine and finishes the corn fit for the market. The other machine has vibrating screens, Barrows and Stewart's improved spring shakers, crop elevators, &c., and the dressing apparatus is at the side. A simple, light, and very effective grinding mill is also exhibited at this stand. The grinding surfaces are of the best French burr stone, and will grind all kinds of corn for feeding purposes and fine flour for domestic use. The Oxfordshire wrought-iron cattle crib is another feature in the machinery manufactured by this firm. This new and cheap implement will, no doubt, come into extensive use, and will be a great saving to the farmer. The whole of the machinery has the appearance of simplicity, strength, and efficiency.

Messrs. E. R. and F. Turner, of Ipswich, exhibit, at Stand 302, in the Machinery in Motion Department, an 8-horse power portable steam engine and thrashing machine, which are excellent specimens of what such machines should be. The engine seemed to possess that most important qualification, ample boiler room and heating surface, and worked with ease and precision. It was fitted with a very simple reversing apparatus, and the feed pump is arranged so that it might be constantly working, thereby keeping it cool. The thrashing machine was adapted to thrash, dress, and deliver the grain into sacks fit for market. The riddles of this machine were so arranged and balanced that no vibration was noticeable in the machine when working, the advantage, of course, being increased durability. At the same stand is also exhibited a portable engine of 5-horse power, from which power was taken by a pulley and strap on to a line of shafting, which again transmitted power by same means to a portable corn grinding mill, oil cake breaker, and two large-sized crushing mills. The grinding mill was fitted with French burr stones, 3ft. diameter, and was of the same design and construction as that which gained the first prize of the Royal Agricultural Society of England in 1867. The feed arrangement was on the silent system, and the mill was constructed with all the latest improvements. Its adaptability for connection with similar mills, so that several might be driven by one pulley, was much in its favour. The oil cake breaker was one well adapted for farm purposes, where large quantities of cake require to be broken, or for a small oil mill. It was capable of breaking about two tons per hour. The arrangement for altering the size of pieces broken was good, as by its means both ends of the rolls were acted on at once, and equal wear of the rolls and equal sized pieces broken were thus insured. Of the crushing and grinding mills it is needless to say much, as they are so well known. Every practical farmer who studies economy should be in possession of these machines. At Stand 44, the same firm exhibit specimens of their smaller machines, amongst which, as might be expected, their crushing mills play a conspicuous part. Two specimens of oil cake breakers for hand power, and a chaff cutter, were here also shown. Some excellent gear works with intermediate motions were also exhibited. The smaller of the two was especially adapted for a pony or mule, and we should think was a very useful implement. The intermediate motion of the larger gear work was fitted with a clutch, by means of which the driven machine may be started or stopped whilst the horse is in motion. A malt mill with equal rolls was very noteworthy for the superiority of its feed and pressure arrangements. The latter was effected by a screw and compound wedge acting on both ends of the roll spindles at one time, thus ensuring equal wear on the rolls, and producing an equal sample. A machine for shelling maize attracted our notice. This was very simple and efficient, and by its action the heads of maize are thoroughly cleaned of the grain. We were informed that this was much in request where maize is grown. This firm have also a 10-horse power portable engine at the stand of the Dunstan Engine Works Company, where it is employed to drive their patent stone breaker.

Messrs. Richmond and Chandler, of Salford, Manchester, make, perhaps, the most extensive display of agricultural implements and machines in the whole yard. First in order, stand their celebrated chaff machines, and they show no less than eighteen different patterns. Two years ago, at the Bury St. Edmund's meeting, they carried off the first prize for the best hand power chaff cutter, and the first prize for the best cutter adapted for steam power, both of which were constructed on entirely new principles. Since that time, they have still further improved on these designs, and have now introduced the like novelties in four different sizes, from a small machine adapted for hand use up to a very powerful one, calculated to cut three tons of short chaff per hour. The great difficulty hitherto experienced in chaff cutters has been to get them to feed well, and at the same time to cut a good sample of chaff. This has at length been accomplished by means of the patentees' new swivelling rising cover, with spring at top, which keeps a tight pressure on the feed after the material has left the rollers and at the instant the knife is cutting it. Spiral springs, one at each side of the mouth, are introduced instead of the old plan of lever and weight, thereby obtaining a pressure proportionate to the thickness of the feed. The greater the feed the greater pressure is exercised upon it by the condensed position of the spiral springs. Two length-of-cut and an instantaneous stop motion are at the immediate command of the attendant, and are at once regulated by moving a handle working round a half-circle plate. The plan is as simple as it well can be, and there is no fear of its getting out of order. Another novelty in these machines consists of an endless feed web at the bottom of the wooden hopper, which regularly assists the hay or straw in its passage to the rollers, much manual labour being thereby dispensed with. It may, perhaps, be thought that this addition and the action of the springs tends to augment the power requisite to drive these machines, but at the last trial of the Royal Agricultural Society, 28lb. of straw was cut into ⅜in. chaff by hand in less time and with thirty-four per cent. less power than any other machine. Six sizes of corn crushers are exhibited, all adapted for kibbling oats, beans, barley, Indian corn, &c., the fineness being easily adjustable by regulating screws in front of the mills. The rollers are case-hardened and diagonally fluted, and are geared to revolve at different speeds, so that a crushing and grinding action is brought to bear on the grain simultaneously. The smaller sizes of these mills are constructed for hand use; the larger ones are for horse or steam power only. A new 1-horse gear work is shown, which for strength, durability, easy working, and moderate price it would be difficult to match. A large assortment of ploughs, harrows, cultivators, drills, mowing and reaping machines, hay makers, rakes, winnowing machines, turnip cutters and pulpers, steam engine and thrashing machines, churns, &c., &c., complete the collection.

Messrs. Robey, of Lincoln, exhibit three 8-horse power single cylinder portable steam engines, with crank shafts and fireboxes of Lowmoor iron, external plates of best Staffordshire iron, and mounted on strong travelling wheels. They also have a portable combined double-blast thrashing machine, constructed for finishing the corn for market, and which will thrash all kinds of grain without injury to the straw or kernel. This machine is fitted with an apparatus which effectually cleans and bags the chaff ready for food for cattle. It has improved straw shakers, barley mower, and a patent revolving corn screen. We also noticed a portable combined double-blast thrashing machine for finishing the corn for market, and which will thrash all kinds of grain without injury to the straw or kernel. Their straw elevator deserves notice. It is fitted with a circular hopper, by means of which it requires no manual assistance in the delivery of the straw. This elevator will deliver the straw to a height of 25ft. at any desired angle, and is fitted with Roper's patent driving arrangement, which is a decided improvement on all others yet introduced. This firm also show a 6-horse power vertical high-pressure stationary engine, resting on a strong iron foundation plate, which forms the ash pan, and also answers the purpose of a feedwater tank, in which the water is heated before passing into the boiler. We may here refer to a 9-horse power single cylinder traction engine exhibited by this firm. It is constructed with

outside cylinder, and has crank shaft and firebox of Lowmoor iron, and external plates of best Staffordshire iron. To the cylinder of this engine we are desirous of drawing particular attention, as it contains features which, as far as we are aware, are not to be found in a similar engine. The cylinder is enclosed in a wrought-iron steam dome, which not only serves the purpose of a steam jacket, but gives also an immense support to the cylinder itself. This dome is of the same thickness of plate as the boiler itself, to which it is firmly riveted, and the cylinder is so placed within the dome that all the working strain, which in this class is very great, is taken by the dome, and has not to be sustained by the bolts through the cylinder to the boiler.

One of the most attractive features of the show was a new system of brakeing for railway carriages, which was exhibited by the inventors, Mr. J. Cockshoot, jun., coachbuilder, of Strangeways, Manchester, and Mr. Weatherill, his foreman. We purpose shortly to illustrate this brake ; in the meantime, we place before our readers the follow- description :—On the centre of each axle is fixed a pinion, gearing into a sliding rack extending from end to end of the carriage, supported by a bearing or box working freely on each axle and covering the pinion. The rack is kept in gear of the pinion by springs bearing directly on the back of the rack when travelling through the grooves in the bearing boxes. By a further arrangement of springs, fixed in the centre of the carriage framing, the rack, when thrown into gear by guard or driver, presses firmly against the springs, and by their gradual compression effectually stops all further progress of the carriage or train when at full speed in an incredibly short distance. When any portion of the train with the ordinary brakes becomes detached, the arrangement is useless, unless accompanied by a guard to put the brake on. Such, however, is not the case in the Cockshoot and Weatherill brake. The instant any portion of the train becomes unhooked from its couplings, a lever, previously held in a vertical position by a clip spring, is permitted to drop, and kept down by a sliding weight. During the descent of this lever a short heelpiece at the fulcrum end falls directly over the projecting end of the sliding rack, gradually and firmly pushing it into gear with the pinions on the axles, by this extremely simple and safe action preventing further progress. Provision is also made for arresting the train when necessary before entering the station by a movable lever working upon a stud fixed to the rail or to a post. This lever may be actuated by chains or rods, as in the case of signals or switches, and in connection with the signal lights, under the control of a duly authorized person at the station. When it is desired to arrest the progress of a train to prevent threatened danger, this lever is lifted from its horizontal position by pulling the chains or rods connected to a reversing lever, and in the passing of the train strikes a small projecting lever fixed to the under part of the carriage frame ; the reverse end presses the rack into the already described position. The brake is continuous, the rack of each carriage butting or pressing on the end of each preceding carriage, and requires no couplings. The brake of each carriage is a perfect brake in itself, as was amply and satisfactorily demonstrated on a small railway with a steep incline laid down at the Manchester Show.

The same firm exhibit several specimens of their improved carriage axle, deserving of a more than passing notice. The speciality of these axles consists in a rearrangement of that portion of the axles technically known as arms or bearings, working freely in the box securely embedded in the nave of each wheel To illustrate our point, it will be quite sufficient if we state, when the axles break short off, the wheels at once become detached from the main body of the axle, and the vehicle, of whatever class, as a matter of certainty, turns over, to the discomfort if not danger of its occupants. The construction of this invention secures an unbroken connection between the vehicle and wheel, even if every axle arm or bearing is broken in the box of each wheel. By the insertion of leather washers between the collars on the arm or bearing in the box, and a simple method of screwing up, chattering or joggling—the results of loose fitting or wearing away—is obviated. The axles, as shown in several forms, is a perfect safety axle, simple in construction, durable in wear, readily oiled and cleaned, and we are sure must commend itself to the public. We select for brief notice from the sundries of inventions—all of a high class—Mr. Jos. Cockshoot's bevelled box hinge, specially adapted for landaus, barouches, broughams, and other carriages, affording greater width of doorway, increased facility of ingress and egress, while all moisture is effectually excluded from the woodwork. The same inventor patents a new shield or guard to cover the joints on hooded carriages, by which all moisture is kept from the trimmings, presenting a decidedly improved appearance. We wish also to notice the capital platform or artificial slab, 60ft. long by 21ft. wide, and about 3in. thick, laid down by the Liverpool Patent Cement Company to sustain the tramway for the working of Messrs. Cockshoot and Weatherill's patent railway brake. It is an admirable specimen of indurated stone. It is impervious to damp and unaffected by heat, and is the cheapest material out for all kinds of floorings or public footpaths. It is also superior and cheaper than bricks or stone for house building. We would advise builders and others interested in the use of such materials to minutely inspect this "big flag," and to obtain from the Company's agents further particulars as to its adaptability, utility, and cost.

Fire engines are well represented at Manchester. We have, first, Messrs. Merryweather and Sons, of London, who exhibited three steam fire engines of different sizes, all, as usual, fitted with the well-known "Field" boilers. Two of the engines are of the same pattern as the engines "Le Prince Imperial" and "L'Imperatrice," which gained the first prize gold medal for these makers at the late Paris Exhibition. The third engine is a novelty as regards weight and price ; it weighs but one ton, and being mounted on high wheels and easy springs, can be drawn by one horse or a few men ; its price is about 25 per cent. lower than any steam fire engine yet offered ; its design is strong and simple, and its finish equal to the well-known character of Messrs. Merryweather's work. These makers also showed a brigade manual power fire engine, a two-wheel or curricle fire engine, fire pumps, hoses of various kinds, hose reels, &c. With regard to the "Field" boiler, with which Messrs. Merryweather's engines are fitted, we may mention that it was exhibited as an agricultural boiler at the great show at Beauvais, France, where it obtained the only medal awarded to this class of boiler. Messrs. Shand and Mason, of London, exhibited two examples of their engines, which were types of those manufactured by this firm for the Metropolitan and other fire brigades, the Admiralty, and foreign governments. The third exhibitor in this class was Mr. Thomas Rose, of Victoria-street, Manchester, who has had twenty-five years' experience in the manufacture of fire engines. Mr. Rose had an extensive show, consisting of five fire engines of various sizes, an improved form of fire escape, reaching a height of 60ft., numerous pumps, hydrants, joints, pipes, hose, &c., &c., all of which showed careful design and good workmanship. Mr. Rose's brigade engine is used in Manchester and many surrounding towns.

Messrs. S. Owens and Co., of Whitefriars, London, have no special novelties, but what they have is well worthy of notice. They exhibit their improved double-action steam pumping engines, of various sizes. The peculiarity in these engines is in the arrangement and form of the valves, which are readily accessible. These engines are adapted for supplying farm buildings with water, breweries, &c., or feeding boilers of any size. They also exhibit various descriptions of fire engines suited for large establishments, mansions, farms, &c. ; also the noted Cassiobury fire extinguisher, as designed by this firm for the Earl of Essex, and several hundreds of these useful engines have since be supplied to the nobility and gentry in various parts of the country. There were also working models of the hydraulic ram to be seen in operation. These convenient machines are of great service for the supply of mansions, &c., where a small fall can be obtained. They are self-acting, and for every foot of fall will raise water 10ft. and force it any distance. Mr. Bernay's improved centrifugal pumps were shown, of all sizes, for drainage or other purposes where large quantities of water are required. Messrs. Owens had also their usual display of force pumps for house and garden use, stable and farmyard pumps, water carriers and garden engines, hose, pipes, and every variety of hydraulic appliance.

Messrs. Allen Ransome and Co., of Chelsea, had a fine show of wood-working machinery, which attracted considerable and well-merited notice. There was first an equilibrium deal frame (Frazer's patent). These machines are furnished with two separate swing frames worked from one crank shaft, so arranged, that when one is at the top, the other is at the bottom of the stroke ; and thus in ascending and descending, they counterbalance each other, and the result is that they can be driven at 400 revolutions per minute with less vibration than any other deal frame driven at half that speed, and the necessity for a flywheel is obviated. The swing frames are made entirely of cast steel, thus combining great strength with the least possible weight, and the crank shaft and other working parts do not require to be nearly so strong as in other frames, in which a heavy swing frame is counterbalanced by a heavily-weighted flywheel. Messrs. Ransome showed their self-acting saw-bench, into which several patented improvements have been introduced. The chief of these improvements consists in a very simple arrangement for feeding the timber up to the saw, which obviates the many disadvantages attending the employment of the complicated system of spur and bevel wheels which has hitherto been employed for the purpose. This feed motion has been fully described and illustrated in the MECHANICS' MAGAZINE. The feed motion is driven from the saw spindle, and can be varied so as to bring the timber forward at rates ranging from 15ft. to 60ft. a minute. The feed rope is coiled round a large drum at the end of the bench, and the gearing by which it is worked is boxed in and effectually protected by the framing of the machine. When the feed motion is thrown out of gear the rope readily uncoils from the barrel, which runs round freely upon a fixed pin. To these exhibits, we may add Messrs. Ransomes' general joiner, planing and trying up machines, and their plain band saw machines. These latter machines are intended chiefly for sawing curves, and among the many purposes for which they are peculiarly adapted may be mentioned sawing out hand rails, gothic work, &c., cutting out buffer blocks, break blocks, curved supports for roofs of railway carriages and trucks, &c., &c. These machines are fitted up in the best style, and by simply changing the saw it is equally adapted for cutting out the most delicate ornamental work, or for sawing through a piece of oak 15in. thick. At this stand, we also noticed a very ingenious and practical

method of coupling shafts on a self-centreing principle; we defer our description of this device until another occasion.

Messrs. Clayton and Shuttleworth, of Lincoln, had as usual an excellent show of portable, fixed, and traction engines, as well as thrashing and finishing machines, straw elevators, &c. We would here call particular attention to the rolled steel beater plates for thrashing machines made by this firm, the form of which has earned for them a reputation as being the best beaters for thrashing perfectly clean without injuring the grain. Hitherto, these plates have been made of malleable cast iron, the great objection to which is its softness and consequent liability to wear rapidly and become smooth on the surface. This objection, however, has at length been entirely overcome by the adoption of rolled steel, which invention has been patented. Messrs. Clayton and Shuttleworth have recently effected an improvement in the construction of their adjustable corn screen, which effectually prevents the steel spiral springs being broken, either by accident or otherwise. It consists in thoroughly binding every coil of the spring to each corresponding coil of the cylinder with wire, and afterwards strongly soldering all together, so that they cannot possibly work loose. The screening wires are attached to the spiral springs, which latter keep them at equal distance apart. There is a screw inside the hollow shaft for expanding or contracting the cylinder endwise by imparting motion to one of its ends. The spiral springs connect the cylinder ends together; they must consequently expand and contract with the cylinder, and in doing so they make the meshes between the screening wires coarser or finer. An important matter, as showing the demand for the portable engines of this firm, and also as a testimony of their high character, is the fact that Messrs. Clayton and Shuttleworth turned out 102 engines of this class in May, and 104 in June last, besides other machinery, and to judge from the appearance the firm made at the show, we should think the latter number will be far exceeded in July.

Messrs. F. and C. Hancock, of Dudley, exhibited at Stand No. 137, several of their new screw propellers, which are being brought into note by their superior performances. There were a pair of four-bladed screws of 30in. diameter, and which are about to be tried by Government, at Portsmouth, in a steam launch. At the same stand we saw a variety of dairy and other implements of the most ingenious character. There was, notably, Hancock's butter machine for washing butter from milk and acid, as well as for cooling and making it firm in hot weather. These points were most satisfactorily demonstrated during our stay at the stand. The machine, which consists of a small cylinder in an iron frame and a screw piston, was placed in a tub of cold water, and a sample of butter was put into the machine. The screw piston was brought to bear upon it, and in a minute the butter was pressed into the water in the form of vermicelli. The action of the water upon these thin filaments of butter absorbed the whole of the acidity and salt. The filaments were readily put together into a large lump of butter by a pair of wooden pats, and on inspecting the sample before and after the operation, we found that the butter acted upon by the machine was considerably sweeter, and quite delicate in taste, whereas the original sample was strong in scent and somewhat rank in flavour. These machines will prove a boon to every household, especially in London, where we never expect to have butter over fresh. At Stand No. 126 we found Mr. J. L. Hancock's anatomical steel bed, one of the most ingenious devices we have seen, even from this ingenious firm. The bed, which consists of a series of inclined steel bars, is simply placed upon any ordinary bedstead; a thin hair or straw mattress is placed upon the steel ribs, and the apparatus is complete. The ribs, which are 3in. wide (rounded on the surface) are placed 1in. apart from each other, and cannot possibly cut or injure the bedding. The open space under the ribs affords the most perfect ventilation, and the very gentle elevation of the upper part of the bed makes it one of the most delightful adjuncts to repose. In hot climates, where a thin, cool, and soft bed is so much wanted, it will be a boon. The inclination from the head to the foot can be regulated to any angle required, by means of two adjusting screws. As a novelty at a show of this kind, we may mention a valuable picture by Hogarth, which has never before been published, but of which Mr. Hancock is the fortunate possessor. The picture represents a romantic episode in the life of the Earl of Peterborough, the hero of the war of succession in Spain. The earl is dancing on the lawn in front of the grand portico of Bevois Mount, with the celebrated singer Anastasia Robinson, whom a year previously to his death he publicly acknowledged as his countess.

Our space demands that we should for the present bring our notice to a close, but before doing so, we would refer to the excellent display of leather machine bands made by Messrs. Webb and Son, of Stowmarket. These bands are of all sizes and lengths, whilst their quality is such that we feel a pleasure in commending them to the notice of steam power users, to whom a gennine article is of the first importance in driving. We shall resume our notice next week, when we shall describe some further novelties which we have in reserve.

THE FAIRLIE STEAM CARRIAGE.

THE steam carriage, which we partially described last week, is specially designed for working passenger traffic on branch lines or light railways, and forms, in combination with Mr. Samuel's patent, one of the systems so pertinaciously—and, we must add, ably—carried out by Mr. Fairlie. The arrangement consists in placing a long carriage on two four-wheel bogies or trucks, which respectively support the front and rear ends of a carrier frame, on which the main body of the carriage is constructed. In the construction of the hind truck there are no peculiar features, but the leading truck, which has coupled wheels 3ft. 9in. in diameter, is fitted with steam cylinders, and carries on its platform an upright steam boiler. The cylinders are inside, and are 8in. in diameter, with 12in. stroke, and the driver's platform, which gives every accommodation that the most fastidious drivers could wish for—every valve and handle being nicely arranged to his hand—is housed in much after the American fashion. The fact is, that Mr. Fairlie has made his footplate into a very comfortable place, his object evidently being to take every care and to afford every comfort to that most useful and most neglected class, engine drivers, in whose hands we risk our lives every hour, aye, every minute of the day.

At the leading end the carrier frame is provided with a strap, which completely encircles the base of the boiler, this strap being fitted with brass rubbing pieces on the inner side, so that the base of the boiler, which really forms a large bogie pin, can revolve freely to the extent of a quarter of a circle. At the hind end the carrier frame rests on the centre of the trailing bogie, this latter being arranged so that it can swivel freely, and being provided with four ordinary carrying wheels 2ft. 6in. in diameter. The carrier frame, besides keeping the two bogies at their proper distance apart, supports the carriage body and receives all shocks or strains. It is made of longitudinal frames, with cross frames and diagonals, the longitudinal frames being strengthened by truss rods, and the inside frames being connected, for a portion of their length, by plates at the top and bottom, so as to form a long shallow tank about 4ft. wide by 12in. deep, which is destined to feed the boiler. Under this arrangement, the tank serves to materially stiffen the carrier frame, and, at the same time, the weight of the water is distributed over a considerable length of the latter.

On the carrier platform is placed a carriage body, this latter being perfectly distinct from the carrier frame itself, and being merely a covering for the passengers, so that it can at any time be readily removed for repairs, and another bolted on in its stead. Instead, however, of removing the carriage body from the carrier frame, the latter may be readily detached from the engine, by simply taking out the bolts of the strap which embraces the base of the boiler. The engine can then be attached to another carrier frame. When the engine is detached, the front end of the carriage is supported on a pair of auxiliary wheels, which, by means of screws and a hand wheel with suitable gearing, can be lowered down so as to bear on the rails when desired. The ready means which are afforded for the detachment or separation of the various parts of Mr. Fairlie's steam carriage forms an important feature in his system, and one which will very greatly facilitate the execution of repairs. The construction of the carriage body is varied by Mr. Fairlie, according to the nature of the traffic which it is designed to work. That we saw tested accommodated 66 passengers (16 first class and 50 second), with a compartment for the guard; the compartments are furnished in the most handsome manner, and everything is done that careful consideration could give to the increased comfort of the passengers. The arrangement of the lamps is especially good. We strongly recommend our friends, particu larly the South-Western Railway authorities to profit by the example, if only in this respec alone, set them by Mr. Fairlie.

In the construction of the vehicles, steel is used instead of iron, in all parts where its employment is advantageous, and care has been taken, by properly proportioning the various details, to avoid all unnecessary weight. The weight of the whole vehicle without passengers, but with fuel and water for a 40 miles run, is 13½ tons, whilst with 66 passengers the weight would only be 18¼ tons, of which rather more than half would rest on the wheels of the engine. It will thus be seen that the ratio of unpaying to paying load is, when the carriage is fully loaded, only about 2¼ to 1, while as about 55 per cent. of the total weight is available for adhesion, the carriage would be readily able to mount gradients of 1 in 16, if sufficient cylinder power was provided. In the case of the steam carriage we describe, however, the cylinders have not been made large enough for this kind, it having been designed for running on lines with inclines not steeper, say, than 1 in 40—gradients which it would mount with ease. On a line with moderate gradients, say, up to 1 in 100, and at speeds varying from 25 to 40 miles an hour, such a steam carriage as we have described should be run with a consumption of about 8lb. of coal per mile, and with a correspondingly small consumption of oil, tallow, &c. The expense for wages also would be very small, as the engine could be readily managed by one man, while the guard would have charge of the brake, and would be able to collect fares. There is a wide step, or rather platform, on each side of the carriage, with a suitable hand rail on the outside all round the carriage; the guard can thus pass round the carrige with safety. The passengers from any compartment can also pass at any time to the guard, and thus there is the most perfect method of communication between passenger and guard.

Although the total wheel base of the carriages is 39ft., yet the actual wheel base, which has to be considered when estimating

the capability of the vehicle for traversing curves, is that of each bogie, or 6ft. only. With this base the carriage can be safely run round curves of 40ft. radius at 15 to 20 miles an hour, while, at a slow speed, a curve of 25ft. radius may be traversed. Thus, by placing circular curves of 25ft. radius at the terminal stations, the carriages can be run round, and the expense of turntables avoided.

The steam carriage possesses ample power to draw, under ordinary circumstances, another carriage behind it. In the case of a railway laid on the common road, such speeds as 40 or 50 miles per hour would never be attempted, a speed of 10 to 15 miles per hour being more nearly the maximum; and, in such instances, the boiler would possess ample power to supply the cylinders with steam at the full pressure admitted for, say, three-fourths the stroke, and ample tractive power would thus be afforded for drawing another carriage or trucks loaded with goods. Altogether, Mr. Fairlie's plans are exceedingly well considered, and we feel sure that, at the present moment, when light railways are the subject of much attention, they will be regarded with great interest.

THE FRENCH ATLANTIC CABLE.

SINCE our last report of the progress of this enterprise, the major and most difficult part of the work has been successfully accomplished; the entire deep sea section between Brest and St. Pierre has been laid, and communication established between the two places; the work, so far as the "Great Eastern" has been engaged in, has been completed, and the big ship is now on her way to England, to get ready for a work as great, if not greater than the present.

The table we published brought the operations of the expedition down to the 7th inst., and the statement we now give brings the important work of laying the deep sea section to a conclusion. There is but little to add to the statement, for the operation of laying progressed in a most satisfactory manner, nothing interfering to stop progress. Even a gale of wind with heavy sea seemed to raise no impediment in the way; it was only when the actual destination was arrived at, and the look-out ships met with, that delay took place. They came into a thick fog (the prevailing weather off that coast), and were compelled to buoy the cable, and it was not until three days had elapsed that the weather sufficiently cleared to allow of the splice being made between the deep sea portion and the intermediate part laid by the "William Cory." This was, however, successfully accomplished on the evening of the 14th, and on the following day, and since, frequent messages have been transmitted.

The total amount of cable paid out has as yet not been officially announced, but the amount expended has been considerably less than the amount provided; there will, in all probability, be nearly 200 miles to spare in the deep-sea section alone. From the most reliable calculations obtainable, it will be found that the entire length of cable submerged between Brest and St. Pierre is about 2,595 nautical miles, a length that constitutes this cable the longest ever laid, and in all probability it will hold its pre-eminence in that respect for many years.

The laying of the St. Pierre and Duxbury section is proceeding satisfactorily. The "William Cory" commenced paying out the shore end from St. Pierre at 10.50 a.m. Greenwich time, on the 15th, having landed the end and proceeded paying out through the night. At 9.0 a.m., on the 17th, she completed paying out what she had on board, and the weather being too rough to permit of the splice being made, the end was buoyed. The weather sufficiently moderated to allow of the splice being made on the following day, and the paying out of the main portion of the cable

continued from the "Scanderia." At noon of the next day, the 19th, their position was lat. 44·21, long. 62·28. Payed out from St. Pierre, 321 miles; distance run, 306 miles; slack about 5 per cent. On the 20th, at noon, lat. 43·27, long. 64·13; distance run, 399 miles; cable payed out, 421 miles; slack, 5·5 per cent.; delayed ten hours by a foul flake. On the 21st, lat. 42.5, long. 66·31; cable payed out 545 nautical miles; weather foggy. The "William Cory" had payed out of the different sizes, 173 miles of cable; the "Scanderia" had on board 450 miles, and the "Chiltern" 153 miles. Taking the present rate of progress, the work should be completed this week, and we trust that no further causes will arise to prevent the final completion of the work. We are glad to find that there is now no cause for the unpleasant rumours that were circulated relative to the prevention by the United States of the landing the end. A telegram has been received from the agent of the Company to the effect that permission for landing the cable has been given by the Government of the United States, on conditions accepted by the agent of the "Société" in the United States.

THE FALMOUTH, GIBRALTAR, AND MALTA TELEGRAPH COMPANY.

IT is now some years since the Government contemplated laying a submarine cable to Gibraltar—not only contemplated, but had progressed so far as to specify the form of cable, and its manufacture was commenced. The destination of the cable was suddenly changed, and the Gibraltar scheme lay quiet for some time. It has, however, been frequently on the *tapis* with very uncertain signs of success. It is now nearly ten years later that a company is formed for this object, and, we are glad to say, at last with every prospect of success.

There has lately been an extraordinary amount of confidence in telegraphs, partly due to the successful operations with deep sea cables, the certainty of laying them, and the feasibility of effecting repairs in deep water; and probably also due to the Government scheme for the purchase of the "telegraphs." The immediate cause of the announcement of the present company is the successful working of the direct Malta and Alexandria line, and the proposed continuation from the latter place to Aden and Bombay. The "present company has been formed for the purpose of completing the system of submarine telegraph lines between England and India, worked throughout by English hands, and under one management. This object, so important for imperial and commercial interests, has long engaged the attention of the directors and others interested in placing telegraphic communication with the East on a thoroughly sound and efficient footing. Until it is effected, messages between England and India must traverse 2,000 miles of wire through France and Italy, and will continue liable to those frequent and vexatious interruptions and delays which experience shows to be inseparable from long land lines of telegraph."

The present submarine cable system is from Malta to Egypt and from Egypt to India. The line now in course of construction will, it is anticipated, be submerged by May next. It is therefore proposed to lay the present cable from Falmouth to Gibraltar and Malta by that time, so that we should have simultaneously a long submarine route through to India. The length of cable required will be—

	Nautical Miles.
Falmouth to Gibraltar . .	1,431
Gibraltar to Malta	1,025
Total . .	2,456

Provisional agreements for working have been entered into with the Anglo-Mediterranean and British Indian Submarine Telegraph Companies, and a contract has been entered into with the Telegraph Construction

and Maintenance Company for the "making and laying (under similar conditions to those of the Atlantic cables) the line between Falmouth and Malta for £640,000, of which amount £50,000, in fully paid shares, is to be reserved until this company's engineer has certified that the whole line has been successfully laid and in working order. The cables are to be laid by May 31, 1870, at which date the entire line between Falmouth and Bombay will, it is believed, be complete." There are no difficulties in the way of the work; the soundings throughout the route are well known, and confidence now is thoroughly established in deep-sea submarine cables, that we doubt not that the whole of the capital £660,000 (less £50,000) has been readily subscribed.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

THE SETTING OF CEMENTS—DEFECTS OF GAS BURNERS—A POWERFUL GALVANIC BATTERY—TO DISTINGUISH BETWEEN PRUSSIAN BLUE AND ANILINE OR INDIGO BLUES.

THE cause of the setting of hydraulic cements has been investigated by several chemists, who have in general agreed that it is owing to the formation of a double silicate of alumina and lime and the absorption of water. The question may be said to be set at rest by some researches of M. Frémy, who has shown that when an argillaceous limestone is calcined, at a dull red heat, a partial decomposition of the clay takes place; the silica and alumina, in fact, are separated, and are made free to combine with the lime when the cement is mixed. This is not really novel information; but the truth is shown more clearly by the experiments of M. Frémy. The part which the free lime plays is also made clear. If this be dissolved out by weak acid, or water, or syrup, the residue of silica and alumina will not set under water, but the cement may be reproduced by the subsequent addition of some lime.

As an addendum to the remarks made in this journal some weeks ago on the defects of gas burners, we may mention that Mr. Kirkham, of the Imperial Gas Company, has made a further series of experiments on the burners in common use, and has found as great variations in their illuminating power as those stated by the Gas Referees. Too great prominence can hardly be given to the facts arrived at, for they concern all gas consumers, who are naturally anxious to get the full value of what they pay for, and they are of equal interest to the makers of burners, who may learn from the experiments the principles which must guide them in producing good burners. The variations in the different kinds of burners extended, in round numbers, from 15 candles to 5 candles for an equal consumption of gas. This lowest power was found in a fishtail burner, such as is in most common use; and the faulty manufacture of these is shown by the circumstance that burners of the same number, which ought, therefore to give an equal light, varied in illuminating power from 11 candles to 6 candles for the same consumption of gas. In the end, perhaps, it may be found advisable to give consumers some guarantee for the proper construction of a gas burner, for it is clear that they are at present supplied with articles which rob them of half the value of the gas they pay for.

A galvanic battery of great power is described in the French journals. Two carbons are placed together in a large porous vessel with a mixture of bichromates of potassium and sodium, and perchromate and persulphate of iron. In the outer vessel zinc and a saturated solution of common salt are used. The poles are to be placed as near together as possible, and to be of the greatest extent possible. It is easy to see that such a battery must be of great power. For equal size, it is said to have twice the power of the bichromate battery with two liquids, and eight and a-half times the force of the single liquid bichromate battery. The uses for such a battery are not numerous, but, when great intensity is required, and an instrument of small bulk is convenient, this combination may be recommended.

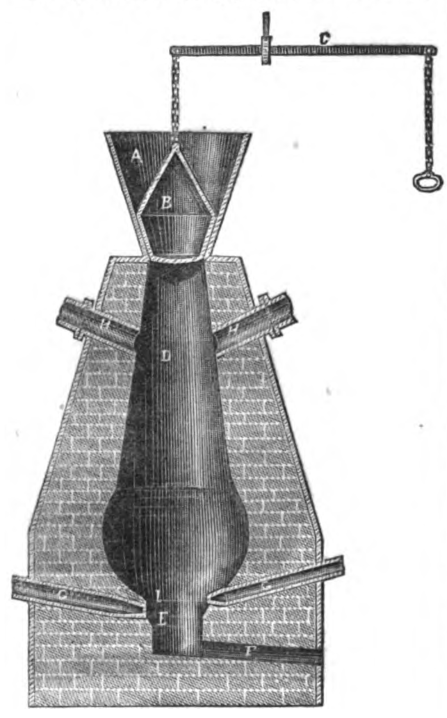
A test for distinguishing a Prussian blue from indigo and aniline blues is given by M. Nickles. Fluoride of potassium, he tells us, will discharge the Prussian blue colour and not affect the indigo or aniline colour. The information may prove of use to calico printers. Ordinary writing ink, it seems, is also decolourized by fluoride of potassium. Whether it has much effect on the paper we are not told.

MANUFACTURE OF PHOSPHORUS.

AN invention has lately been patented in England for the treatment of materials intended to produce phosphorus directly in the presence of the fuel inside a blast furnace, in which the combustion is accelerated by the application of an air blast. The invention is due to M. Claude Brison, of Châlons-sur-Saône, France. The principal advantage of this new application of blast furnaces in combination with blowing machinery, consists in substituting for the laboratory apparatus hitherto employed for this purpose an industrial apparatus, namely, the blast furnace, of simple construction and operation, thus really rendering the manufacture of phosphorus an industrial operation capable of being carried on on a large scale. This apparatus may be employed with equal advantage for producing both varieties of phosphorus, namely, the ordinary phosphorus and the amorphous phosphorus.

The apparatus employed, shown in section in the accompanying cut, consists of a furnace of fire-brick enclosed in a sheet-iron casing, at the top of which is a cast-iron hopper A, for receiving the materials, which is closed by means of a valve B, capable of being raised by the lever C. The materials to be acted upon, together with the fuel, are filled into the chamber D of the furnace, where they are heated to a high red heat, the combustion being intensified by the action of a blowing engine. They attain their highest temperature when they arrive at the tuyeres G G; the gaseous products of combustion and the vapours of phosphorus escape at the exit pipes H H, while the slag or cinder collects in the space E, from which it is run off through the passage F capable of being closed.

The operation of the apparatus is as follows:—



After having brought the chamber D to a red heat by the use of fuel only (coke or charcoal), it is filled with fuel to about the height of the pipes H, from which point it is filled with alternate layers of fuel and of the mixture intended to produce the phosphorus. The valve B is then closed and a blast is forced in of sufficient pressure to force the liberated gases through the water of the condensing vessels. The blast is continued as long as alternate layers of the carbonaceous and other materials are introduced into the furnace. The mixture employed for producing the phosphorus consists of phosphate of lime, silica, and carbonate of soda, the whole thoroughly desiccated. The addition of the soda has for its object to form the double silicate of soda and lime, which is more fusible than the silicate of lime alone. When the mixture arrives at the part I of the furnace, where it attains its highest temperature, the silica liberates the phosphoric acid from its combination with the lime, and this acid is reduced by the excess of carbon. If any part should escape reduction it would soon become decomposed in passing through the carbonaceous layers in the upper part of the furnace, in the presence of an atmosphere surcharged with carbonic oxide. The phosphorus escapes through the pipes H H, which convey it to the condensers. In this process, therefore, the phosphate of lime is attacked by the silica, producing silicate of lime; the phosphoric acid is in its turn reduced by the carbonic oxide, which, in taking up the oxygen from the phosphoric acid, is converted into carbonic acid and liberates the phosphorus.

THE BESSEMER HIGH-PRESSURE HOT-BLAST FURNACE.

MR. BESSEMER has recently filed the specification of another invention, which is of great importance in the production of iron and steel. Its main features may be regarded as an embodiment, for the purpose of fusing malleable iron and steel, of the experience gained by, and principles proved in, the Bessemer converter. It has long been understood that Mr. Bessemer has been directing his rare ingenuity to some good plan for melting old rails and similar work; and we suppose that this patent, forming by its length almost a volume on metallurgy, is one of the principal results. The system also appears to have already been thoroughly worked out in practice. Mr. Bessemer first of all refers to what is really the distinguishing feature of his converter—the rapid way in which it produces the required heat:—"Intensity of heat, rather than quantity, is the condition essential to the successful working of furnaces employed" in melting wrought iron or steel containing little carbon. A substance which requires 3,000 degrees of temperature to produce fusion may be kept at a temperature of 2,900 degrees for whole days in succession without becoming thoroughly melted, when the mere addition of only 100 or 200 degrees of heat would, in that particular case, have produced a complete fusion of the substance in a very short period of time. In order to obtain this intensity, or rapid development of the heat required, Mr. Bessemer has recourse to air at both a high temperature and a high pressure. Atmospheric air and other gaseous fluids in a heated state acquire a still higher degree of temperature by their compression "into a smaller space." "Such increase of temperature being in proportion to their reduced bulk, or to the number of atmospheres forced into the space usually occupied by one." He therefore constructs furnaces of sufficient strength to withstand an internal pressure of two or more atmospheres, observing that he does not propose by this means to generate a greater quantity of heat by the combustion or union of a given quantity of carbon and oxygen than is obtained by such means in well constructed furnaces; for the compression of the gaseous products of combustion within a furnace does not generate heat, but merely concentrates into a smaller space and gives greater intensity to the same quantity or number of units of heat as would have existed in a more diffused state had not pressure been applied. Hence, wherever the temperature produced by the combustion of fuel in ordinary furnaces, having a free escape to the chimney, is sufficient for any desired object—as, for instance, the evaporation of water in steam boilers—a loss would be sustained by compressing the gaseous products of combustion in such furnaces, for the amount of engine power required to compress the gases would exceed the power obtained from the increased quantity of steam generated in consequence of such compression, all other conditions being equal. But when the highest temperature produced in ordinary furnaces with a free escape is actually less, or where it only by small amounts exceeds the temperature absolutely required in any process, the case is entirely altered. Though a very high temperature, dependent on the pressure used, may be thus produced, Mr. Bessemer prefers, in order to have a moderate wear and tear in the furnace, a moderately rapid fusion. He states that, "in a small furnace using coke as fuel, with a cold blast of 20lb. per square inch, and a pressure of 17½lb. in the furnace over that of the external atmosphere, small test pieces of cold wrought iron were fused with

HIGH PRESSURE HOT BLAST FURNACES.

BY MR. BESSEMER.

FIG. 3

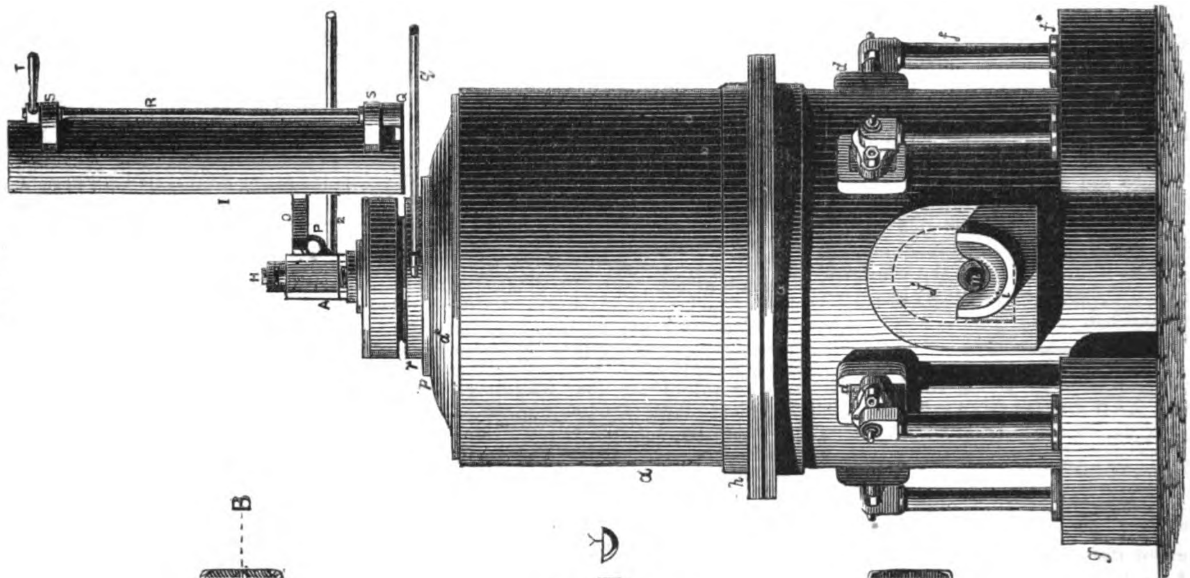


FIG. 2

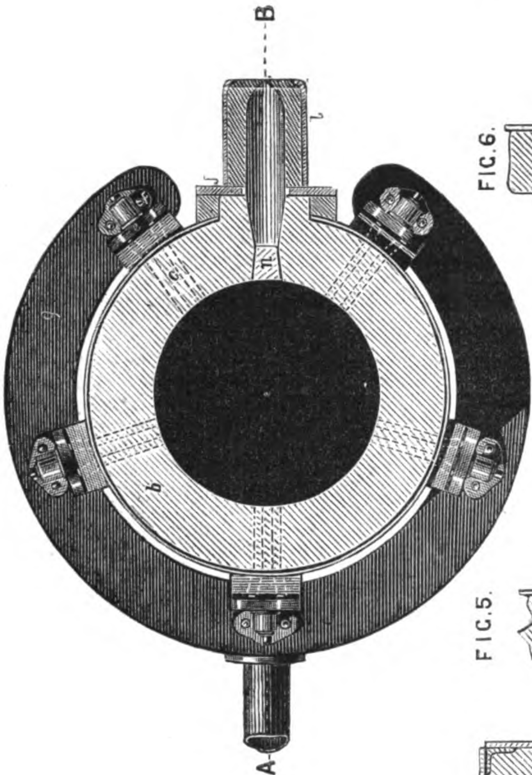

FIG. 6

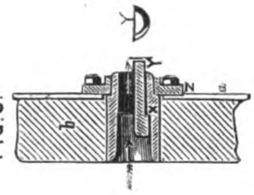

FIG. 4

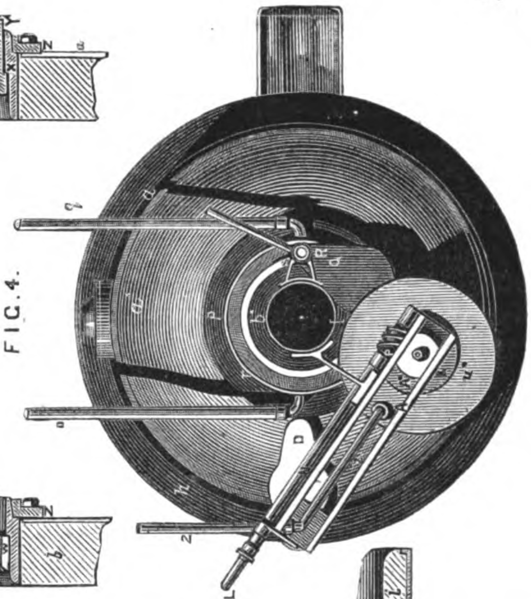

FIG. 5

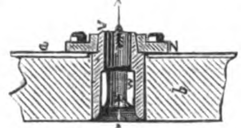

FIG. 1

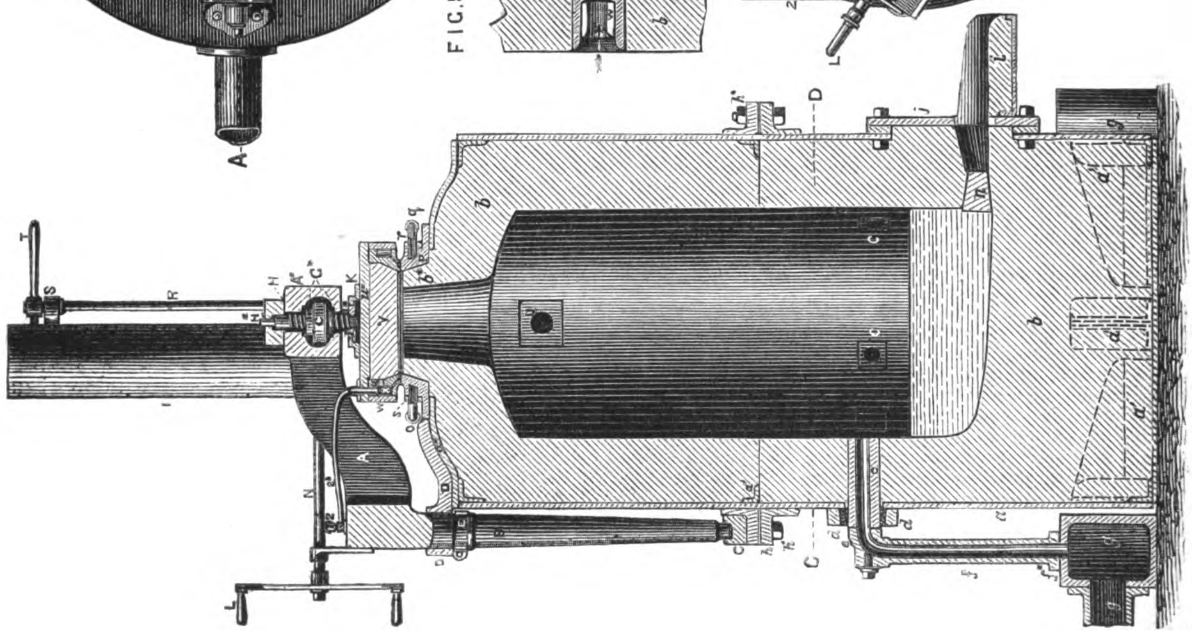


great rapidity. For example, a piece of 2in. square wrought-iron bar, 12in. long, weighing 13lb., was introduced cold into the furnace and was completely fused in five and a-half minutes. In the same small furnace, 3cwt. of wrought-iron scrap was put in cold, and was poured fluid from the furnace after an interval of fifteen minutes. The furnace was then working with an average internal pressure of 15lb. to 16lb. per square inch in excess of the pressure of the external atmosphere."

He believes "that a pressure of 20lb. to 30lb. over that of the external atmosphere will be found the most economical in practice, for it is probable that if a much greater pressure is employed it would raise the temperature so high as to drive the iron rapidly off in the form of vapour," as, in fact, generally occurs towards the end of the process in the ordinary Bessemer converter. The materials to be melted in these furnaces are puddled iron or steel, finished iron or puddled steel bars cut into lengths, or steel purified by nitrate of soda, the crop ends of rails, old rails, ladle sculls, and other scrap. They are also to be employed in melting up the mixed steely metal for casting railway crossings, wheels, bells, anvil blocks, stamp heads, guns, mortars, and other articles. The system is to be applied to cupola furnaces, crucible furnaces, and reverberatory furnaces. In all these cases the outer shell is preferably made of iron or steel boiler plate, with all the joints well caulked and made airtight, and sufficiently strong to resist the internal pressure, though cast-iron shell may also be used. The furnace is to be lined with Stourbridge firebrick, Dinas bricks, plumbago, or also ground ganister on the plan now

adopted for the Bessemer converter. To fuse wrought iron or steel without so much reference to purity as to cheapness, Mr. Bessemer prefers to apply this system to a cupola furnace, having a dome through which the metal and fuel are admitted. The circular door is carried on a movable iron arm, which itself carries an upright cylinder with a movable bottom, and into which the charge of fuel and metal is put to be fed in. To preserve the door from the heat and prevent leakage of flame and gases, a hollow channel is made round the door frame, into which steam or air, at a higher pressure than that within the furnace, is conveyed. The escape opening for the products of combustion can be altered in area by the insertion of small pieces of fireclay. Several fireclay tuyeres are used for conveying the heated blast, which is also at a pressure from 2lb. to 6lb. higher than that in the furnace. A plan is also shown whereby powdered materials may be conveyed by the blast into the furnace. The cupola can be taken in two in order to be able to line it, in the same way as the Bessemer converters are lined. To show the transformation operated on the ordinary cupola furnace by Mr. Bessemer, we have chosen this form for illustration, though the cupola on trunnions, like the ordinary Bessemer converter, may be regarded as a more perfect shape.

Fig. 1 is a vertical section on the line A B of fig. 2, fig. 2 is a horizontal section on the line C D of fig. 1, fig. 3 is a front elevation of the furnace, and fig. 4 a plan of the upper part of the same, and figs. 5 and 6 vertical sections of the escape aperture. *a* is the outer shell of the furnace, formed of strong plates of iron, riveted and caulked airtight, and having gusset pieces a^1 to strengthen the bottom of it; *b* is an internal lining of firebrick, plumbago, ganister, or other refractory material; *c c* are fireclay tuyeres, moulded square externally, and having a round hole through them for the passage of the blast; they are inserted through the square iron frames *d*, which are secured by countersunk rivets to the shell *a*, and are bevelled on the inside; the outer end of the tuyeres *c* are enlarged or made taper, and the space between this enlarged part and the bevelled sides of the frames *d* is caulked with iron cement (iron borings and sal ammoniac), so that the escape of gases from the furnace around the tuyeres is prevented, and the pressure of the flanges *e* of the blast pipes *f* against the enlarged end of the tuyeres is also prevented from forcing the tuyeres *c* into the furnace by reason of its enlarged end and the iron cement around it, while the blast pipe flanges *e*, by being bolted to the iron frames *d*, also prevent the internal pressure acting on the end of the tuyeres from driving them outward; the blast pipes *f* are bolted to the main air trunk *g* by flanges f^*. An equilibrium valve is placed in the main pipe g^* near to the furnace, by means of which the blast may be turned on, or off, or moderated. The feeding door of these furnaces is so small that it is necessary to provide a special means of entering the furnace for re-lining the interior from time to time for the purpose of giving convenient access to all parts of the interior. The furnace is divided into two parts by massive angle flanges *h h*, which are faced so as to form an airtight joint, and are secured together by bolts and nuts, as shown at h^*. When the furnace is to be repaired, the upper part may be lifted off with a crane, when the lower part will be readily accessible. A small flange a^1 prevents the brickwork of the upper part from being displaced when lifted off. The furnace is provided with a spout *i*, lined with loam, for conducting the metal into the casting ladle. A door *j* is formed at this part, having only a small opening in it. By unbolting the door and removing part of the lining the furnace may be cleaned out, the lining being afterwards made up as in ordinary cupola furnaces, or a conical piece of firebrick, as shown at *n*, may be inserted, so that when the metal is to be drawn off from the furnace, the workmen, instead of having to drive a hole through the solid material with a pointed bar, will simply drive the cone *n* into the furnace, and thus open a passage at once equal to the size of piece attached. A small crossbar and screw may be employed to prevent the accidental blowing out of the cone, the bar extending across the door *j*, and the screw pressing against the small end of the cone *n*.

In order to secure the feeding door against a leakage of the products of combustion, and against the force tending to force it open, on the upper or crown plate or dome a^* of the furnace is riveted a stout ring of iron *p*, around which a hoop *r* is tightly shrunk on, leaving a space or annular channel S, in which water circulates, for the purpose of keeping it cool. The water is supplied by the pipe *o*, and after circulating round the ring *p*, it escapes by the pipe *q*; the ring *p* is also further protected by the lining of the furnace, as shown at b^*. The frame *u* has a channel *x* formed around its exterior surface, over which a hoop of iron *w* is shrunk, so as to complete the annular passage *x*. The lower surface of the frame *u* rests on the upper surface of the ring *p*. The under side of the frame *u* has a small V-shaped groove turned in it, and at about an inch apart all round this groove small holes are drilled, which pass upward at an angle and connect the V-shaped grooved channel with the annular space *s*. A pipe 2* conducts air from the main blast pipe into the channel *x*, which passes thence down the numerous small drilled channels, and thus supplies air under pressure to the V-shaped groove before named. Now, the pressure of the blast exceeds the pressure of the gases within the furnace; consequently, any imperfection in the fitting of the door frame *u* down upon the upper ring *p* of the furnace, instead of allowing the highly-heated gases to escape and act destructively on the metal fittings, such gases are prevented from escaping, because, in case of imperfect fitting of the metallic surfaces, the air under pressure in the V-shaped groove will, by reason of its superior pressure, force its way between the imperfect joint, partly escaping in the upper part of the furnace and partly into the external atmosphere.

In order to remove the door *u* from the mouth of the furnace, and readily replace it as required, a sort of crane arm is employed, consisting of two stout plate iron cheeks A A, bolted to the crane post B; this latter is supported at its lower end in a socket C, bolted to the angle flange *h*. The upper end of the crane post is supported by a strong bracket D, having a hole through it, in which the crane post turns; at E is a movable collar, fitting into a journal formed on the crane post, for the purpose of preventing the crane post from lifting upward, when pressure is applied to the furnace door; between the cheeks A a piece of iron A* is firmly bolted, having a slot in the centre, in which a worm wheel G is fitted. This wheel and its elongated bosses G* form also a screw nut, through which the screw H works, a square part H* being formed on the upper end of the screw, to prevent its turning round, but not preventing its free motion upward or downward through the block of iron A*, the holes in which are of a diameter equal to the largest diameter of the screw, and have no internal threads formed in them, the holes merely acting as guides for the screw H, which carries on its lower end a plate fitting loosely inside a flanged ring K, which is secured by bolts to the upper plate of the furnace door. The object of the ring K and the loosely fitting plate is to cause the door when lifted to be suspended in a horizontal position. The freedom thus given to the door is for the purpose of allowing it always to find its proper bearing on the ring *p*, the end of the screw H then coming in contact with the upper plate *u* of the door will bind it firmly on its seat. For this purpose the handles L are mounted on the shaft N, which also carries the worm P; this worm gears into the wormwheel G, by the rotation of which the screw H is made to rise and fall without rotation, carrying with it the door *u*. Two stops may be used to prevent the crane arm from being moved too far in either direction. For the introduction of fuel and metal into the furnace there is used a vertical feeding cylinder I, made of thin plate iron, secured by a strong iron bracket O to the crane arm. The lower part of the cylinder I has a plate Q (fig. 3) fitted to it. The plate Q is keyed on to an upright spindle R, supported by bearings S attached to the side of the cylinder, the upper end of the spindle having a handle T, by means of which the plate Q is made to close or open the bottom end of the cylinder.

While the furnace is under blast, the workmen will put a charge of coke or other fuel into the cylinder, and along with it the scrap or other malleable metal to be fused, and when the cylinder is filled the blast may be turned off, the handles L put in motion, and the door *u* lifted sufficiently to allow the crane arm to be moved round until the feeding cylinder I is brought vertically over the mouth of the furnace. A slight movement of the handle T will remove the plate G from beneath the cylinder, and allow all the fuel and metal to fall at once into the furnace. The crane arm is then quickly moved back into its former position, and the door is again forced down by turning the handles. Immediately after the closing of the furnace, the blast is turned on, and the operations of the furnace resumed, and at such intervals as is found necessary, the same operation may be repeated. In the plan, fig. 4, the crane arm is shown in the position it occupies during the time that the fuel is being discharged into the furnace. The plate Q is also shown removed from under it. Mr. Bessemer prefers to take the supply of air to the door *u* from the main blast pipe at a point where the equilibrium valves does not shut off the supply. The air will thus continue to flow during the time the fuel is being supplied to the furnace, and the act of moving the door again over its seat will cause the numerous jets of air from the small drilled passages before named to blow away with considerable force any small particles of fuel or other matter from the surface against which the door fits.

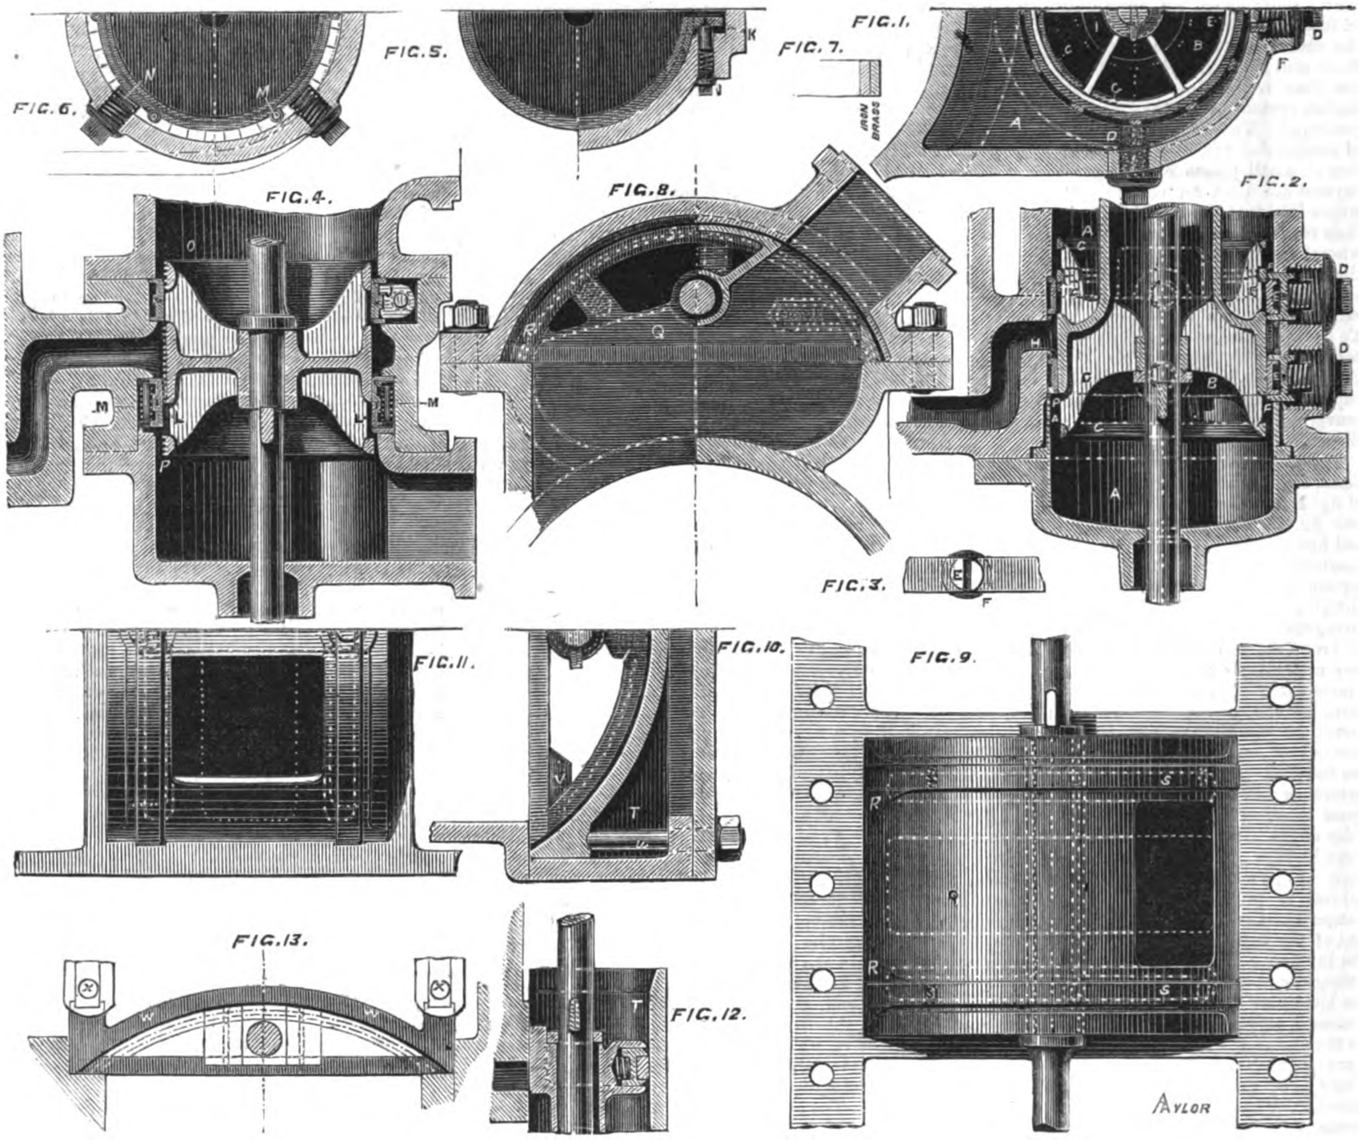
In order to admit of the motion of the crane arm and to continue the connection with the air supply, the pipe 2 is taken to the top of the crane post, and is there jointed to the pipe 2*; this piece of pipe 2* is made of thin copper or pewter, and will spring sufficiently to allow of the slight rise and fall of the furnace door. One of the chief peculiarities of this mode of working furnaces under a high pressure of the gaseous products within them is the outlet for the escape of flame, so different to the ordinary cupola furnace, where the outlet is generally equal to the full diameter of the furnace. When working under pressure in one of these high-pressure furnaces, an opening of 2¼in. in diameter has been found sufficient for a furnace whose transverse area is 572 square inches, the outlet being about 144th part of the sectional area of the furnace. Thus it has been found that with an internal pressure of 16lb. to 18lb. per square inch in excess of the atmospheric pressure, one square inch area of outlet may be reckoned approximately as the area required for every 2cwt. of coke burned per hour in such furnaces.

The outlet of the furnace at U in its simplest form consists of a square block of firebrick, having a round hole in it of the desired size. It is made with a shoulder externally, which abuts against the interior of the casing *a*, to prevent its being forced out by internal pressure; a slight difference in the area of the outlet materially affects the condition of the furnace. In fig. 5 is a vertical section of the outlet block V, having two internal diameters, forming a shoulder. Into this a small fireclay cylinder W is put, for the purpose of contracting the area of outlet; and at fig. 6 a similar outlet block is shown at X, having a small piece of moulded firebrick Y inserted therein, and projecting sufficiently to be lifted out by a pair of tongs and be replaced by other pieces of different sizes. In both figures is shown a flange plate Z, by which the outlet blocks are retained in place. By unscrewing this flange plate, the outlet block, when too much worn, can be readily replaced by a new one.

The amount of pressure up to which the gaseous products are kept within the furnace will depend chiefly on the regulation of the pressure of the blast, the escape aperture being also regulated so as to prevent the pressure going below or getting above the point desired. In some cases, the escape of the flame and heated matters may be regulated by a loaded valve, the face of which is formed of well-burned clay, in which case, a stop may be provided, so as to prevent the valve from entirely closing. There is also specified and illustrated, as before stated, a cupola movable on trunnions, but embodying a similar mode of constructing the outer shell, of making and fixing the tuyeres, the crown and upper part and crane post, furnace door, and feeding cylinder. The fuel used in these furnaces is preferably hard coke or anthracite coal; but combustible gases may also be used. The gas is generated in the ordinary way, and forced by a blowing engine into a gas receiver, where it is compressed. The form of furnace then used for melting steel and malleable iron by gas is the reverberatory, of brickwork, as usual, but enclosed in a strong iron casing, with a door on the plan described for the cupola. In the reverberatory form of furnace, liquid hydrocarbons can also be employed, either alone or with solid fuel. The liquid fuel is introduced into the blast pipe, and taken in by the blast in the form of spray. The metal to be melted may be protected from undue oxidation by coating it with a mixture of clay, lime, and sand, with or without red ore or alkaline salts. Crucible furnaces on this system are made with a cylindrical fuel chamber, supplied with blast in the same manner as the cupola furnace, with a similar regulation for the pressure.

IMPROVED SLIDE VALVES.

BY MR. BEATTIE.



BEATTIE'S SLIDE VALVES.

In our notice of the last conversazione of the Institution of Civil Engineers we briefly referred to an improved slide valve, which was exhibited by Mr. Beattie, the locomotive engineer of the London and South-Western Railway. We now place before our readers full particulars and illustrations of that gentleman's invention in that respect, which he has recently patented. We may premise that Mr. Beattie's improvements consist in constructing slide valves in such a manner as to relieve them from or to reduce the pressure of the steam thereon and the consequent friction attending their movement. For that purpose he forms the valve and the interior of the steam chest of a cylindrical shape, and extends the steam ports partly round its circumference. He forms the steam port bars of loose circular rings of metal, in one or more parts, inserted in grooves in the steam chest, and compressed against the cylindrical valve by metallic springs or by an adjusting screw, arranged to draw the ends of the rings together, so as to form a steamtight contact with the valve, and to compensate for the wear of the valves and rings. At each part where the rings are cut a circular recess is made in the steam chest, larger in diameter than the width of the rings, and into this recess is fitted a small cylinder, grooved across the end to receive the ends of the ring, and shaped to the same radius as the inside of the rings, and in this manner the steam is prevented from passing through the space between the ends of the rings. Beyond each end of the valve, and inside the exhaust port of the valve, a ring of metal is projected, forming part of the valve and connected with it, and turned to the same diameter as the body of the valve, so that the packing rings are prevented contracting to a less diameter than the valve when it is open for the admission of steam or for the exhaust.

This invention and its modifications are shown in the accompanying engravings. Figs. 1 and 2 show transverse and longitudinal sectional views of a cylindrical steam chest A A and valve B B. The valve B B is formed smaller in diameter than the interior of the steam chest, and is carried by the circular rings C C, which form the bars of the steam ports, and are compressed on to the valve B B by the springs at D D. The packing rings are formed of the section shown at C C, fig. 2, and are cut at E E. At the parts where the rings are cut the steam is prevented passing between the ends by means of the cylindrical bolts F F, figs. 1, 2, and 3, which are formed to receive the ends of the rings and to overlap the openings. At suitable distances from the body of the valve the rings G G are formed, and placed so as to prevent the packing rings contracting to a less diameter than the valve when it passes beyond them. In figs. 1 and 2 the rings C C are shown retained in their position by the rings H H, which are not in contact with the valve and serve only to control the position of the rings C C, and are suitably formed for that purpose. The valve is shown constructed to allow the passage of steam through it at I I. Figs. 4 and 5 show the rings designed so as to be contracted on to the valve by the screws at J J acting on the lugs K K, and placed so as to be adjustable from the exterior of the steam chest.

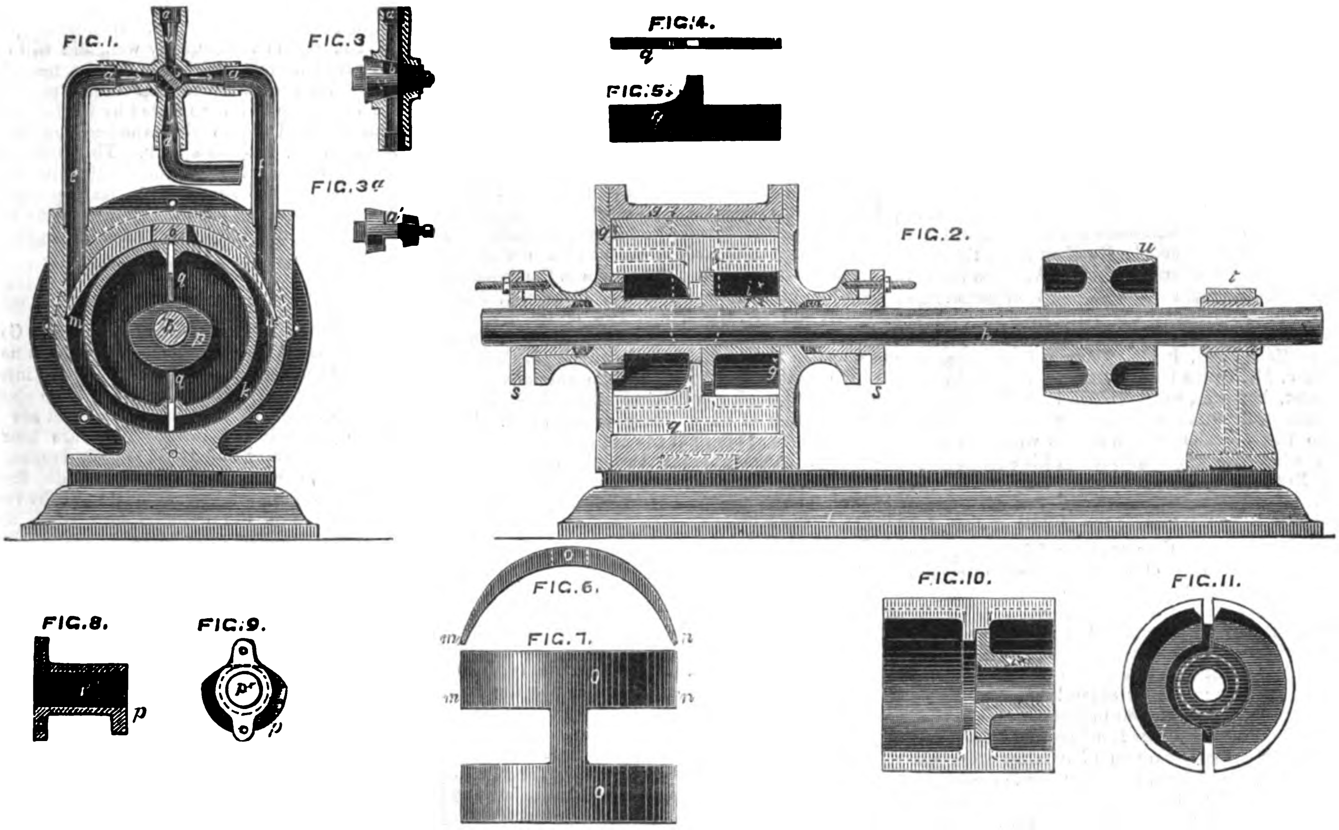
Figs. 5 and 6 show the packing rings formed of two narrow rings connected together laterally by suitable projections and recesses L L, and expanded against the sides of the grooves which contain them by the springs M M. In fig. 5 the steam chest is shown constructed in several parts for the facility of introducing the packing rings. The packing rings may be contracted inwardly by the springs N N, or fitted externally with rings of some more expansible metal, and riveted together at the ends where cut so that they will be contracted together inwardly when warm (see fig. 7). At O O, fig. 5, the outside of the valve is shown, having grooves formed in it to assist lubrication, and reduce the pressure of the rings if the steam be admitted behind them, as at P P, figs. 5 and 2. The valve shown at fig. 5 is for the steam ports of one end of the cylinder, and is connected with the valve of the other end of the cylinder by means of the valve spindle.

Fig. 8 is a transverse sectional view of a valve and steam chest, and fig. 9 is a plan of the valve. The valve Q Q is formed to a slightly less radius than the interior of the cover, but is fitted to the cover, as shown at R R, for a short distance of the curve. The rings S S are pressed into the angles formed by the cylinder facing and the steam cover. The valve is formed hollow to allow the passage of steam through it, and the exhaust steam passes out through the back. The packing rings are pressed against the cover by springs, as shown at *s s*.

Figs. 10, 11, and 12 are views of a valve adapted to the common form of steam chest. The cover T T is secured to the cylinder face by the studs U U, and the valve is shaped to a less radius than the interior. The packing rings are in two pieces, and the steam is prevented passing the ends where the rings are cut by the cylindrical cover plate, as described in figs. 1 and 2. The ends of the rings are pressed by the springs at V V into the angles

BENNISON'S ROTARY ENGINE.

MANUFACTURED BY MESSRS. BRAE AND CO.



formed by the cylinder facing and cover. Part of the back of the valve between the packing rings is removed to allow the exhaust steam to circulate there, and to reduce the weight of the valve.

Fig. 13 shows a valve adapted for the inside cylinder of locomotive engines, and is similar to the valve shown in figs. 8 and 9, with the exception that the valve spindle is attached to one end only, and the valve is not hollow for the passage of steam. The steam covers W W are pressed to the cylinder facings by the wedge bolts X X.

BENNISON'S ROTARY ENGINE.

WE have recently examined a novelty in rotary engines and pumps, which works without friction or loss of steam. The credit of the invention, which is illustrated in the annexed engravings, is due to Mr. H. L. Bennison, of Greenwich. The engine is constructed with a four-way cock for working supply and exhaust, and has the larger cam made H-shaped in plan, by which means, while the advancing pallet is kept in its necessary position by the extremities of the H, a free passage for the steam or water is provided on both sides of the pallet. By this means, the force exerted by the inner cam to work the pallet is reduced to a minimum, and the back pressure, which otherwise would be exerted against the advancing pallet, is entirely removed. There are also other improvements in detail which will be seen as we proceed with the description of the engine. In our engraving, figs. 1 and 2 are transverse and longitudinal sections of the engine. Fig. 3 is a section through the improved four-way cock. Figs. 4 and 5 show one of the pallets; figs. 6 and 7 the larger cam; figs. 8 and 9 the smaller or inner cam; and figs. 10 and 11 the internal cylinder by which the motion it receives is transmitted to the driving shaft of the engine.

The four-way cock is seen in figs. 1 and 3, at the extremity *a* in each arm; the internal form is circular, and thence, as seen in fig. 1, it changes by a diminishing taper to or very nearly to the plug seat or plug *b*, which, in the figure, appears in cross section; but, in fig. 3, which presents the plug to view so as to show its side or length, it will be noticed that the internal form changes from *a* by an increasing taper to the plug seat or plug. Fig. 3^a is the plug removed, side view showing the recesses a^1 a^1 on each side, which make the communications between *a a a a*, fig. 1. As placed in the engraving, the upper and lower arms of the cock are for supply and exhaust respectively, and the side arms for passage ways through pipes *e f* communicating with the engine, and to be used one for supply and the other for exhaust, but interchangeable in the use accordingly as the engine is to be worked in one direction or the other. *g* is the external cylinder forming the stationary case of the engine; *h* is the driving shaft passing through its ends; g^x g^x are the cylinder covers, and *i* the internal cylinder which revolves; *k* (fig. 1) is an annular space or pressure chamber between the cylinders, into which the ports open from the pipes *e f* between the extremities of the H-shaped cam *m m* and *n n* respectively of the larger H-shaped cam *m n o*, the extreme ends being recessed into the inner surface of the case *g*, and the central portion *o o* being truly fitted and seated against the top and along the entire length of the annular space, as seen in fig. 2.

By this means, the larger cam occupies a fixed position; *p* is a smaller cam formed at extremity of a flanged collar p^x by which it is held to one end g^x of external cylinder, and also occupies a fixed position; *q q* are the sliding blades or pallets or pistons which lie across the annular space when compelled to do so by the smaller cam (see lower pallet in fig. 1), and lie sheathed within a recess formed for them in the internal cylinder, when compelled to do so by the larger cam (see upper pallet in fig. 1), the action of the cams ensuing on the revolution of the cylinder, which is driven by the pallets, and these being driven by the steam or water power employed. The inner cylinder is so constructed that, in its rotary motion, its periphery forms, by its close contact with the lower side of the H-shaped cam, and with the inner sides of the covers g^x g^x, a perfectly steam tight joint, or nearly so. The internal cylinder is keyed on to the shaft *h*, as at i^x, and drives the shaft *h*. The stuffing box bearings *s s*, at ends of cylinders which partly support the shaft and its further bearing *t* and driving pulley *u*, present no features of novelty. We have described the apparatus as an engine for driving the shaft *h*, but, when employed as a pump, the shaft *h* is used as the driver, the other (moving) parts being driven.

This apparatus is being manufactured by Messrs. J. A. Brae and Co., of the Phœnix Wharf, Greenwich, where we recently examined the working of several which were being used both as engines and as pumps. The engine and pump were each 6in. diameter, the pump having three pallets and the engine two. The engine was geared to the pump by spur wheels, and the latter had a 2-inch suction and a 1½-inch delivery pipe. On being timed, the little pump delivered 75 gallons of water per minute, throwing it to a considerable distance. Both the pump and engine worked very easily, and at high speeds; at low speeds, also, the action was equally even and uniform. It is easily started, and is stopped very quickly. The engine has been driving machinery in Messrs. Brae's shop for the last seven months, and has not required any repairs whatever. In Messrs. Brae's turning and planing shop we found a 12-inch engine which was used for driving machinery that had previously been driven by a much heavier engine. We were well pleased with the working of this engine, which will assuredly find favour with the public on account of its simplicity, efficiency, and economy.

AERONAUTICAL SOCIETY OF GREAT BRITAIN.

A GENERAL meeting of the members of this Society was held at the Society of Arts on the evening of July 14. The chair was occupied by Mr. Charles Brooke, F.R.S., and there was a considerable attendance of members.

Mr. F. W. Brearey, the hon. secretary, requested permission to say that he had lately received a newspaper from Chicago, United States, giving very full particulars of an intended balloon voyage across the Atlantic. Some months ago he had seen an announcement that a M. Chevalier was preparing to leave Liverpool with a balloon of large capacity, having that object in view, but as several such statements had been made, which had resulted in nothing, he had not paid much attention to this one. M. Chevalier claims credit for the discovery of an uniformity of currents. He says:—"In every ascent during his long career, he found, on reaching an altitude anywhere between 8,000ft. and 10,000ft., that the wind was invariably from the west, or rather from the north-west, whichever way the wind was blowing near the ground. And it is for the glory of establishing this theory, rather than of sailing 3,000 or 4,000 miles over the water, that he undertakes this voyage." But this is certainly no discovery of M.

Chevalier's. Mr. Wise, an American aeronaut, says that he "early made it an object to note the influence upon the course of my balloon of the currents of air which I might then happen to encounter. The result of my observations was the discovery of an uniformity in their direction, so marked as to leave it almost impossible that it could be the effect of accident, or otherwise than the natural and prevalent condition of the atmosphere in that portion of the ethereal space. Under whatever circumstances I made my ascent, however contrary to the direction of the winds below, I uniformly found that, at a certain elevation, varying occasionally, but always within 10,000ft. of the earth, a current from the west, or rather from the north of west, invariably prevailed, nor do I recollect a single instance out of 275, the number of my existing aeronautical excursions, in which a different result ensued." He then gives this as a reason why he should fix upon America in preference to England as the point of departure from which to cross the Atlantic. Mr. Low, also an American aeronaut, has made the same observation; and, lastly, though first in point of time, Mr. Green has expressed the same theory. It must, however, be remarked that Mr. Glaisher has recorded "that the too readily accepted theory as to the prevalence of a settled west or north-west wind was not confirmed in his experience." Mr. Brearey said that we might soon have the truth about this theory established, as M. Chevalier intended to start about the middle of July.

Mr. D. S. Brown then read the following paper "On the Economy of Using Power Intermittently for Aerial Support; also Observations on Light Motors and on Balloons":—

In a former paper, I alluded to the apparent ease with which birds support themselves in the atmosphere, notwithstanding that the specific gravity of their bodies exceeds by several hundred times that of air; and I endeavour to account for the fact, by the theory, that power is not required to sustain a weight where no elevation of it takes place, not even in the atmosphere, beyond what is consumed by friction, and the loss, if any, occasioned by the support being of a yielding kind. But, although the air is a yielding support, it is, nevertheless, a most substantial one, for birds use it as a fulcrum in flying, just as well as they do the ground in walking. I therefore inferred that more depended on the application or manner in which force is employed for aerial support than on its absolute quantity, and directed attention to the econmy likely to result from using the power intermittently, as done by birds, and to a still greater extent by insects. The principle is based on the rate at which bodies fall by the force of gravitation, this rate being, as well known, an accelerating one; for example, a body which falls 16ft. in a second only passes through a space of 1ft. during the first quarter of that time, so that if it were momentarily arrested four times during its course, it would only fall 4ft. instead of 16ft., or if arrested sixteen times, only 1ft. It is very desirable that this theory should be put to a practical test, by experiment on a large scale, which may be done in an inexpensive manner, by attaching artificial wings to a light framework, a large central pair, for instance, to act alternately with two smaller pairs on either side of it. By such an arrangement, the machine would be properly balanced, and a sufficient number of strokes obtained to secure permanent support. The wings could be moved by bellows engines, worked by atmospheric air, conveyed in any quantity or manner required, by an india-rubber tube from a pump placed on the ground, and worked by a powerful steam engine, where weight would be of no consequence. If the ground apparatus were placed on a railway carriage, and made to follow the machine in its horizontal course, the aeroplane theory of support suggested by Mr. Wenham could also be tested, and thus the actual amount of power required for flight under every known circumstance ascertained. The intermittent principle may also be tried with rockets, by allowing the gas to escape from them by a number of rapid explosions, following in quick succession, instead of, as at present, in a continuous wasteful stream. Hydrogen gas, or any other explosive substance, could be employed, or even jorks of steam.

A great deal is expected from this society, but I think we may complain of the little support we receive from the public. There is no subject more important than locomotion, and we aim at accomplishing the most perfect system known. Of this, what can be a greater proof than the fact that a small bird like a swallow can in a few days fly from here to Africa, and in as many more cross that continent from one side to the other, whilst it has taken Dr. Livingstone years to perform the same journey on the ground, amidst heat, dust, and other obstacles too numerous to mention. We are not wanting for suggestion, and the scientific resources at our command are unlimited. I have no hesitation in saying that if only a thousandth part of the money which has been worse than thrown away in horse-racing had been expended in aerial experiments, the problem would have been solved long ago.

(To be continued).

NEW POWER LOOM.

DURING our recent visit to the show at Manchester we came upon a power loom which, for simplicity of construction, gives promise of a great change in the arrangement of the working parts of such machines. The loom is the patented invention of Mr. Moore, of 83, Piccadilly, Manchester, and Mr. Gadd, and two of them are in operation in Brown-street Mill, Salford. The loom in question has no crank shaft or tappet shaft, or their consequent wheels, all the motions being conveyed through one driving shaft, placed in the usual position of an ordinary crank shaft. The shaft revolves at one-half the ordinary speed—that is to say, the loom makes two picks during one revolution of the shaft, the cam causing the sley to perform two complete strokes during one revolution of the said cam. The cam is formed with a flange, the outer surface of which operates upon an anti-friction bowl, revolving on a pin fitted in bearings formed in the sley-sword, while the inner surface of the flange operates upon a second anti-friction bowl revolving upon a stud fixed to a drag link, the link oscillating to some extent around the centre of motion of the bowl as the cam revolves, in order that the bowl may accommodate itself to the movements of the cam. As the cam revolves, the bowls are acted upon alternately, and the sley is caused to vibrate, moving forwards to beat up the weft when the one bowl is acted upon, and backwards to admit of the passage of the shuttle when the other bowl is acted upon, the form of cam being such as will impart a movement to the sley similar to the movement which would be imparted thereto by a crank and connecting rod acting in the ordinary manner. The picking shaft is actuated by a tappet fixed upon the shaft, the tappet acting on the arm of the picking shaft, a corresponding arrangement being employed at the other end of the loom. The healds are actuated by levers, a vibrating motion being imparted to them by means of eccentrics mounted on the shaft. Attached to the loom is a new arrangement for putting the requisite drag on the yarn beam without the use of levers and weights, with a very simple letting-back motion—worthy of notice, as it is a cheap substitute for the heavy and cumbrous levers and weights ordinarily used. As the patentees state that the cost of one of their looms, including royalty, is at least 10 per cent. less than the cost of looms similar in reed space and strength hitherto and now being made, it becomes a matter of interest to machinists and manufacturers to give care and attention to this new loom, and to decide whether a radical change in loom construction, such as that here shown, is henceforth to obtain. We hope to illustrate this machine in the course of a week or so.

METALLIC TUBING MACHINE.

AN apparatus has just reached England from the States, which promises to effect a revolution in the manufacture of various kinds of tubes. As we purpose in our next to give an illustrated description of this machine, it will suffice here to say that it consists of a frame or table fitted with a succession of variously grooved rolls set at different angles. The metal strips are fed in at one end of the machine, and the perfect tube rapidly appears at the other. There is also a table with a pair of cutting rolls, by which the sheets of tube metal are cut into strips of sufficient width for the tube. The inventor is Mr. C. Granville Smith, of Chelsea, Mass. We saw yesterday one of these machines in operation at 42, Kirby-street, Hatton-garden; it was working exceedingly well, and turning out lock-jointed tubes with rapidity and exactness. These machines will produce all the various kinds of pipe in common use, either with the lap joint, lock joint, or butt brazed. The lap joint it produces ready for soldering or brazing, and the butt joint the same, while the lock joint leaves the machine completed and in marketable condition without soldering. All these various kinds of pipe or tubing the machine produces at the rate of 60ft. to 80ft. per minute, in any length required. The metal to be made into pipe is passed into the machine in a flat sheet of the proper width, and, passing through, leaves the machine at the opposite end completed. The apparatus is operated by one man, whose only duty is to feed the machine. It works copper, brass, tin, iron, or zinc, equally well, and will certainly prove a great acquisition to tube manufacturers. We are informed that tubing produced by this machine has been tested by the following pressures of cold water:—Brass and copper, 250lb. to square inch, without a leak. Tin, 70lb., with slight leak at about 18lb. Iron, 250lb., with slight leak at about 75lb. Zinc, 115lb., leaking slightly at about 25lb. These are the results of many tests on tubing 1in. in diameter and 12in. in length.

THE GREAT WOLF ROCK.

THE dangerous pile of rocks lying off the Cornish coast known by the above name, is now about to be converted from a source of peril into a beacon of warning. The rocks are situate about eight miles S.S.W. of the Land's End, and are in extent 56 yards by 88 yards. They are nearly covered at low water, and to add to their dangerous character, the water immediately beside them ranges from 30 to 40 fathoms. Placed at the very commencement of the Channel navigation, and their existence almost completely concealed, they have caused the loss of many ships and of many hundreds of sailors. For nearly eight years the Trinity Board have been engaged in the erection of a lighthouse upon this dangerous point, but from the peculiar nature of the foundation the work has been arduous and progress necessarily slow. The time available for working on each tide has been reckoned by minutes, and in the whole eight years the greatest number of hours during which workmen could land has been 313 in one year, but in some years that number has been as low as 83. On Monday the last stone of the lighthouse which now surmounts the Wolf Rock was laid by Sir F. Arrow, the Deputy-Master of the Trinity House. The lighthouse tower is built of solid granite, and stands 110ft. above the high-water level. The lantern and lens have yet to be fitted, but it is hoped that these works will speedily be completed, so that before the present year has run out, the Wolf Rock may no longer be dreaded by the homeward-bound sailor as a hidden peril, but be looked for as a guiding beacon to his welcome home.

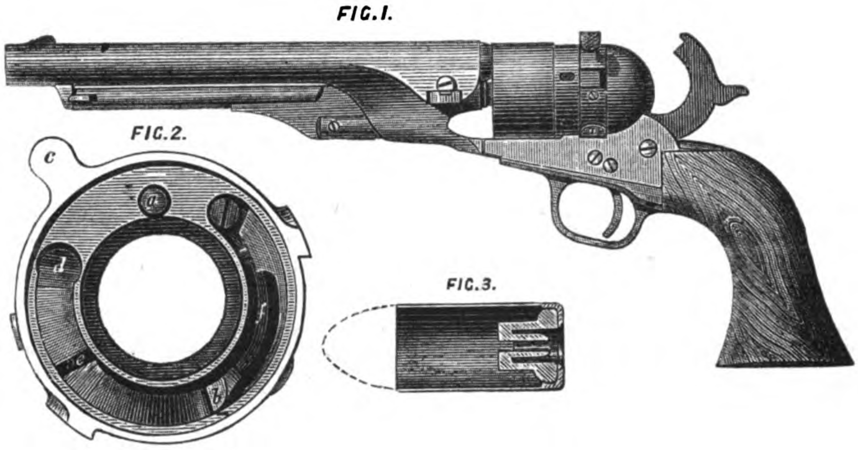
A NEW HOT SPRING.

A STRANGE geological phenomenon caused some excitement last week at Murat, a village situated between the valley of Mont Dore and that of St. James. A civil engineer had caused a rectangular well to be sunk to a depth of 53 metres through a stratum of hard tufa, which covers the primitive formation in that district. At this depth, which is insignificant compared to the shaft of a mine, the heat, nevertheless, became so intense that the workmen had to be relieved at short intervals. Their wooden shoes soon got intolerably warm, and they could not lie down to rest themselves on the hot ground. On the other hand, the appearance of the tufa denoted that the well had nearly reached the granite. The engineer, on leaving the spot for a while, had recommended his men to be very careful during his absence, and to content themselves with removing the rubble, without going further down. One of them, however, in throwing the last shovelful into the skip, took it into his head to remove with his pickaxe a piece of tufa, about 30in. in circumference; but no sooner had he done this than he saw the bottom of the hole he had made swell up. At the same time a loud rumbling noise was heard. The men in a fright jumped into the cage and called to be pulled up; but they had barely got to a height of a dozen metres when a thick column of hot water, preceded by a violent report, rose up in the air, projecting huge stones upwards. The water in falling scalded the men grievously. The jet diminished, and the well filled rapidly, the poor fellows succeeding, however, in getting out in time. In the course of ten hours the well got quite full, and from that time a rivulet of thermal water has been flowing from the spot into the Dordogne. The liquid, on arriving there, still retains a temperature of 40deg. Centigrade. Upon analysis it has been found to contain upwards of 20 milligrammes (nearly half a grain) of arseniate of potash per litre, a proportion unheard of before.

THE COLT BREECH-LOADING REVOLVER.

IT has always been our opinion that breech-loading firearms could only come into universal demand when measures were afforded the user of making—or, rather, of re-making—his own cartridges. A breech-loading weapon, firing cartridges carrying their own ignition, would be useless in some parts of the world, where fresh cartridges were not procurable, after the stock in hand had became exhausted. On the other hand, gunpowder and caps can be had almost anywhere, so that if we give a man a central-fire cartridge, the case of which can be reloaded and primed, we prepare him for almost any emergency of time or distance. The Colt Firearms Company—whose offices are at 14, Pall Mall, London—appear to have had these ideas in view when working out the most recent improvement in their revolvers. This improvement consists in converting the ordinary Colt muzzle-loading revolver into a breech-loader, and especially in providing a cartridge which can be fired and the case re-charged and re-capped a great number of times. The new arm is seen at fig. 1 of our engraving; fig. 2 shows the breech disc, whilst fig. 3 is a section of the new cartridge shell. In converting the present muzzle-loading Colt revolver to a breech-loader, the rear end of the chamber with the cap nipples is cut off, and the disc shown in fig. 2 is substituted. This disc contains the striker and the injector. The striker is a pin, acting freely in the ordinary way; the action of the injector will be gathered from the following descriptions of the manipulation:—The cartridges are placed in the chambers from the front in the ordinary way, and after firing, the disc is rotated a short distance by the projecting lug *c*, until the head *d* of the extractor arrives under the hammer, where the striker was previously. On pulling the trigger, the hammer drives forward the head of the striker and the small bar hinged at *e*, and at the same time causes the ejector *b* to strike smartly the base of the shell, and so to drive it forward out of the chamber. The spring *f* returns the ejector when the hammer is raised. The new cartridge consists of a cylindrical shell of thin sheet brass, open at the upper end, but closed at the lower with a slightly concave disc, which is perforated in the centre, the edge of the orifice being raised externally to receive the cap. The cap having been placed on this projection or anvil in the base of the cartridge, the shell receives a charge of three-fourths of a drachm of powder, over which is laid a lubricated wad, and the whole is surmounted by the conical bullet, and rammed close. The necessary apparatus for re-charging the cartridge cases, consisting of five pieces, is supplied with each revolver, and is very easily manipulated. Some public trials were recently made at the Crystal Palace with the improved revolver and ammunition, and which clearly demonstrated their value. Accuracy and penetration were all that could be desired, whilst it was abundantly proved that with a pound or two of powder and a handful of caps, a man could keep himself well supplied with central-fire cartridges for a very long time. This improvement is a step in the right direction, and will add to the fame of the already far-famed Colt revolver.

THE COLT BREECH-LOADING REVOLVER.



THE "CITADEL" WEDGED-BOLT LOCK.

BY MR. HODGSON.

FIG. 1.

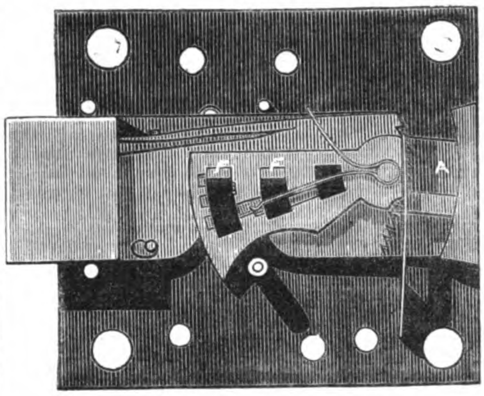


FIG. 2.

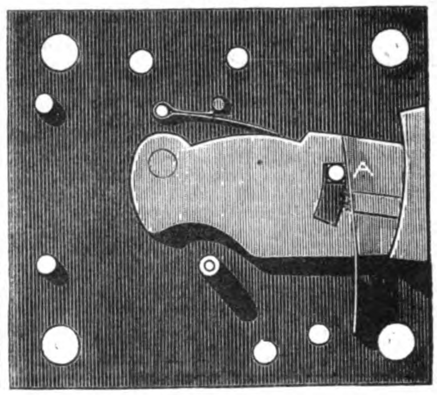

THE "CITADEL" WEDGED-BOLT LOCK.

THE liability of all locks made up to this time to be opened by violence, *i.e.*, by forcing the bolts back, is well known to locksmiths and probably also to most of our readers. The whole resisting force against violence has hitherto been simply the small pin or stump, as it is technically called (marked F in our engraving), which is riveted into the bolt. Thus, whatever the thickness of the head of the bolt, the whole real strength of all other locks depends upon that small pin, and directly that is broken off, the bolt slides back. The object of the inventor of the "Citadel" wedged-bolt lock was to render a lock impregnable against violence as well as fraud, and the "Citadel" lock has therefore a tumbler or lever turning on a pivot underneath the bolt, and carrying a block or wedge A, which, when the bolt is shot out on locking, descends between the rear end of the bolt and the end of the lock, and thereby completely and mechanically fills the space hitherto left vacant behind the bolt of all other locks, and securely wedges the bolt in its locked position. The absolute security from violence, which is the most ordinary fraudulent method of opening a lock, will be apparent to everyone. The key to unlock the bolt first arranges the levers in the usual way, and then, by a simple action on an incline on the talon of the bolt, sends it just sufficiently far forward to release the teeth of the wedge-lever from those of the bolt, and then adjusts the wedge-lever correctly, and withdraws the bolt in the ordinary manner.

The construction of the lock is not complicated in any way, as may be seen from our illustration, nor is there any part of the lock that is liable to get out of order. There are only the same number of pieces as in any other of the best patent locks, but, by their arrangement and action, a double lock is formed by a single action, and thereby double security given against fraud, and, mechanically speaking, absolute security against violence. The principle of the "Citadel" lock is applicable to locks used for every purpose. The engraving, fig. 1, shows a lock made on the "Citadel" principle for banks, iron safes, or other purposes where extraordinary strength and security are required. This lock has a secondary bolt-slide carrying another stump, also marked F. Fig. 2 shows the wedge-lever, with all the other parts of the lock removed. We would add that the "Citadel" lock is the invention of Mr. Hodgson, and is manufactured by Mr. Hodges, at the Bloomsbury Works, Wolverhampton, whose offices are at No. 114, Chancery-lane, London, where we recently inspected several varieties of locks made on the above principle, which is one involving perfect security at a very small cost. The inventor has perfected a highly ingenious mechanical arrangement, and has embodied it in a lock which will ensure the safety of our goods and chattels wherever it is adopted.

THE MAURY BAROMETER.

(E. T. LOSEBY'S PATENT.)

THIS instrument, invented by Mr. E. T. Loseby, of Leicester, in 1860 and 1861, and patented by him, is named after the eminent American geographer and meteorologist, Captain Maury, late director of the Washington Observatory. Captain Maury while visiting England in 1860, pointed out to Mr. Loseby that an accurate and durable pocket barometer was much wanted for many purposes, especially for measuring high mountain ranges, and urged him to exert his mechanical skill in an attempt to produce such an instrument. The conditions laid down by Captain Maury were that the new barometer should range through not less than 15 barometric inches, should be readable to hundredths of an inch, should be compensated for change of temperature, and should not be larger than an ordinary pocket chronometer. Mr. Loseby undertook the task, and in the beginning of the year 1861 he completed an instrument perfectly fulfilling these conditions. But to produce such an instrument in sufficient numbers for successful sale, a staff of workmen, trained to this particular manufacture, was necessary. Meanwhile aneroids were reduced from the original diameter of 5in. to about 3in., and subsequently still further to a size that could be carried in the waistcoat pocket. Time has, however, shown that although the pocket aneroids are handy little instruments, the reduction of size has augmented the errors inherent in the principle. Many inquiries have been made for Mr. Loseby's patent, and one foreign government has offered any reasonable price for it. But it cannot be manufactured for sale to the public until complete arrangements are made for setting up the special machinery which has been invented for producing the several parts in large numbers quickly and accurately, and until workmen have been trained to the use of the tools; considerable division of labour being necessary, to secure cheapness and accuracy. A company has therefore been formed for the purpose of co-operating with Mr. Loseby in carrying out his arrangements for the production and sale of the instrument in large numbers. In the following description, the details of the new barometer are compared with those of the aneroid, in order that the difference of construction may be clearly understood. The Maury barometer contains a vacuum box resembling that of the aneroid in appearance, but made of a material and by a process which give greater permanence to its elasticity in long ranges. The rise and fall of the box is measured by a fine micrometer screw, worked by the observer, and furnished with an index hand. The range may be extended through 24 barometric inches, if required, and the indications will still remain more accurate than those of an average aneroid through one quarter of the range.

The main spring, which keeps the vacuum box distended, is about four times longer than that of the best aneroids, and thus the spring is enabled to expand and contract through four times the range without more strain on each portion of its length. This and the permanent elasticity of the vacuum box are important points; for if their elastic force varied, the top of the vacuum box would not rise and fall equal distances, under equal variations of atmospheric pressure. This rise and fall is exceedingly minute. In the Maury barometer it is only 1-50,000th of an inch for a rise of 10ft. in elevation, and in a pocket aneroid of the same size it is much less, because the Maury vacuum box is larger in proportion to the size of the case, and exposes more than twice the area to the action of the atmosphere. To enable this minute motion to be realized, it may be mentioned that a piece of ordinary note paper would require to be split about 160 times to represent it. To render this motion visible to the eye, it is multiplied in the aneroid by a system of pivoted levers, ending in a chain which is coiled round a small drum, having the index hand attached to its spindle. Now, it will easily be understood by those acquainted with fine mechanism that such minute motions as 1-50,000ths of an inch will be absorbed by the flexure of the levers, the necessary play of the pivots in the holes, and the irregular action of the links of a plate chain not lying closely to the small drum, with only a few grains of power to overcome the stiffness of its riveted links, and displace any dirt that may prevent its close contact; and, further, that the slightest resistance at the multiplied end of the motion will become a large force at the vacuum box, where it will be increased some hundreds of times, seriously opposing its free action; and this disadvantage is increased in the aneroid by the vacuum box having to move all the mechanism and overcome its friction, &c.

In the Maury, the motion of the vacuum box is multiplied by a fine micrometer screw, which is brought into contact directly with the top of the vacuum box, so that its entire motion is shown on the dial by a hand fixed on the screw, and all the intermediate mechanism of the aneroid is dispensed with. The power required to work the screw is supplied by the observer; the vacuum box has nothing to do with moving the indicating mechanism, but is left perfectly free and disconnected with it at the time of observation, with nothing to oppose it in truly balancing itself against the pressure of the atmosphere. The simplicity and firmness of its mechanism, and the small number of acting surfaces, render the instrument very durable, and not liable to injury. It may be subjected to violent shaking or other rough usage, short of breaking the glass or bruising the case, without interfering with its subsequent action; whereas the aneroid is easily deranged by a jerk or a violent shaking. The Maury is compensated for change of temperature, and the higher priced instruments are tested in artificial heat and cold, in a chronometer apparatus, and adjusted until all error from change of temperature has been removed.

The dials have the divisions engraved in a spiral of several coils from the outside towards the centre, and the hand in traversing the whole scale makes as many revolutions as there are coils. This distinguishing feature of the Maury enables the scale to be very long, and allows about four times the number of divisions that could be put on the dial of a pocket aneroid of the same size, if it ranged through as many barometric inches, because the hand of the aneroid would only make one revolution. By this method, and in a small compass, a longer and more open scale is obtained than even that of the upright mercurial barometer, for if the spirals were straightened out, the line would be longer than a corresponding number of inches on the mercurial tube. The dials are usually divided to show feet of elevation direct, without having to refer to a table, as this is found far more convenient for general use in measuring altitudes; but for meteorological purposes they will be divided to show barometric inches instead. Each dial is graduated under the air pump throughout the range, to suit the individual vacuum box to which it is applied, and this is done with all the works in place as they will be used; so that any irregular motion of the box will be allowed for in the dial.

In the aneroid a few points only in the scale are correctly determined; and the interspaces are then divided equally; thus any irregular motion of the vacuum box will always give an erroneous reading at that point; and as it is impossible to make vacuum boxes rise throughout their range with perfect uniformity to the 1-50,000th of an inch, such erroneous readings must be frequent in the aneroids. The table generally used for graduating the Maury dials to show feet of elevation is one prepared by the Astronomer Royal, and a copy of it will be supplied with each instrument, to enable any one to convert the readings into barometric inches, or to employ a different table of values for altitudes. The few acting surfaces in the Maury are of hardened and polished steel, and the workmanship throughout is of a high order. The weight of the instrument is only 8½oz. troy, and of this the silver case forms a large proportion.—"Horological Journal."

PROPOSED GREAT DOCKS FOR THE BRISTOL CHANNEL.

Two schemes of great importance are now occupying much attention in the mercantile circles of Bristol, Gloucester, and South Wales. The Gloucester and Berkeley canal, 16 miles long and of sufficient depth to float ships of 1,000 tons, was constructed 40 years ago by the two greatest engineers of that time—Upton and Telford. The trade, mainly in timber and corn, has rapidly increased, until now it has overgrown the facilities of the port, having regard especially to the enormous vessels employed in the mercantile navy. Brunel, Harrison, Page, and other eminent engineers, have from time to time been consulted, and have recommended extensions, but all their plans were deemed too costly. Last year, the trade of Gloucester was immense, and in consequence of the short time given for the entrance and outlet of ships, and the limited area of the tidal basins there, ships were often detained in Kingroad for weeks. To remedy this state of things, the "Times" states that a plan of improvement has been proposed by Mr. Clegram, the resident engineer, and endorsed by Mr. T. E. Harrison, the hydraulic engineer, for an extension from a point one mile above the present outlet to Holy Hasle Pill, three-quarters of a mile below. It is more than curious that this extension has never been proposed before, inasmuch as by an outlay of £150,000 a new entrance can be provided, with a tidal basin 700ft. long and 300ft. wide; a lock 320ft. long—inside this a dock 2,000ft. long and 355ft. wide; and a new communication to the present canal of about 800ft. in length, 150ft. in width at the top, and with a depth of water of 19ft. Thus accommodation would be given for the largest ships that can navigate the estuary of the Severn from Kingroad to Sharpness. This scheme may, therefore, be regarded as that for the greatest improvement of which the port of Gloucester can at any time be capable. The Board of Trade has been consulted, and it is understood that the president has approved the plan; and as the harbour, in the event of war, would furnish a refuge for gunboats and a means of repairing them, the right hon. gentleman is believed to be prepared to recommend the Government to make the grant of the necessary capital. The new docks would enable steamers of the largest ordinary class to discharge, and then to turn before leaving; they would avoid in many cases the necessity for swinging ships in the rapid tidal way of the Severn; and as the site is only some four or five miles from the trunk line of the Midland Railway, the docks and the line might easily be brought into communication. In connection with this matter has been revived the great project of bridging the Severn, which, it will be remembered, excited so much attention in Parliament, when, four or five years ago, Mr. Fowler proposed a monster bridge, and an Act for its construction was obtained, notwithstanding that the scheme was opposed by all the local and nearly all the railway interests; the purpose was the bridging of the river from Oldbury across the sands to the western shore, a distance of five miles, at an estimated cost of about £800,000. Nothing has been done, either by way for carrying out this scheme or of carrying out another for which an Act was also obtained—that for bridging the river at Newnham, some ten miles higher up. A plan is now under consideration for constructing a subway from the western shore to near the contemplated new docks. This would materially shorten the distance between London and the Dean Forest and the South Wales coalfields; and the result of a recent survey is that by the construction of the new docks and of the subway, or of an equivalent bridge, the Government mineral and woodland property in Dean Forest, 25,000 acres in extent, would be improved to the value of £40 an acre, or, in all, £1,000,000 sterling. The cost of the subway is set down at £250,000—a mere trifle when contrasted with the enormous cost of the gigantic bridge at Oldbury, which would be the largest in the world, and not greater than the cost of the Newnham bridge. The present scheme would be far more efficient than either of the other two; for it would connect the South Wales and Midland systems, and would afford a constant export trade in coal and iron from the contemplated docks at Hazle Pill. Last year, shipping representing between 200,000 and 300,000 tons left Sharpness empty to seek cargoes in South Wales. If the docks are constructed and the subway is made, ships will be enabled to load at Hazle Pill, and the consequent improvement in the value of the Forest of Dean coalfield will be enormous. It is therefore understood that the Office of Woods and Forests is prepared to recommend a loan of £250,000 for the construction of the subway. The Gloucester and Berkeley Canal Company will meet within the next few days to decide whether they will apply to Parliament for powers to carry out as much of this great work as they are immediately interested in.

Mr. Theed has finished the heroic-sized marble statue of Lord Derby, for which he was commissioned by the town of Liverpool, and which is about to be placed in the Town-hall.

Correspondence.

RIFLING SMOOTH-BORE GUNS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—In the Mechanics' Magazine for May 14 1869, we observed a drawing and description of a plan for enabling smooth-bore guns to spin elongated projectiles by means of a spiral rod secured to the breech of the gun in the centre of the bore. The plan is there attributed to Mr. C. Pemberton, R.N., who is stated to have commenced his experimental firing with it in 1865. We wrote on May 21 to inform Mr. Pemberton that the plan had been invented by us more than three years before his experimental firing commenced; but the letter, which was addressed to the Mechanics' Magazine Office, has been returned to us without having found him; we therefore send the facts for publication in your journal.

Our experimental shooting with the plan commenced in February, 1862, and was chiefly carried on by Colonel Sir H. Halford and ourselves at his private range at Wistow, near Leicester. The shooting occupied some months at various ranges from 200 to 700 yards, and led to some important improvements which advanced the principle considerably beyond the stage shown by Mr. Pemberton. During the experiments, many hundreds of rounds were fired from our different small models, and the accuracy of our smooth-bore "spit gun," as we named it, exceeded that of a gun of the same bore rifled in the ordinary way. Having arrived at this point, Messrs. Robertson, Brooman, and Co., of 166, Fleet-street, took out a provisional patent for us in June, 1862, and we submitted the invention to the Government in September following, and asked that the plan might be tried on large guns. But the Government declined to take up the matter, and we found that any experiments in shooting large guns would have to be conducted at our own expense, and further trials were therefore stopped.

But the results we had obtained left no doubt then, and we have none now, that the principle will answer for large guns in the form we left it seven years ago; and that it will either spin elongated shot for accurate shooting at long ranges, or discharge spherical shot for battering at short ranges.—We are, Sir, yours, &c.,

M. Turner and E. T. Losbey.

Leicester, July 17.

[Not having Mr. Pemberton's address, we inserted two notices in the Mechanics' Magazine to the effect that a letter awaited Mr. Pemberton at our office. This failing, we opened and returned Messrs. Turner and Loseby's letter to them.—Ed. M. M.]

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscriber of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the Mechanics' Magazine. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, Mechanics' Magazine Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the Mechanics' Magazine, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Naval, Military, and Gunnery Items.

From a Parliamentary return issued on Monday it appears that the expenses incurred in connection with the royal naval review at Spithead, in honour of the Sultan in July, 1867, as nearly as can be determined, were £8,882 14s. 6d.

An official report of the Minister of Militia and Defence of the Dominion of Canada states that the Imperial Government has intimated its opinion that the naval and military assistance afforded by Great Britain to the Dominion must be largely reduced. Halifax is to be considered, however, an imperial station, and 2,000 men are to be left for its defence

CAPTAIN W. E. LEOHE has had the honour of submitting and explaining to his Royal Highness the Commander-in-Chief the principle of his new repeating and breech-loading rifle.

AN armour plate supplied by Sir J. Brown and Co., of the Atlas Works, Sheffield, and selected from a batch intended for the armour of the "Swiftsure," now building, was tried on board the "Comet" target ship in Porchester Creek, Portsmouth Harbour, on Tuesday. The extreme length of the plate was 16ft. 6in., width 3ft., thickness 6in., and weight about 5 tons. It was secured by 16 2½-inch bolts, with ordinary nut and screw, to the backing in the testing battery.

MANY reductions in the coastguard service are about to be made by the Government. The first step in this direction will be immediately taken by the abolition of the coastguard stations at Sittingbourne and Conyer, on the Kentish coast. Judging from the fact that between 7,000 and 8,000 vessels annually enter the creek upon the shore of which Sittingbourne and Conyer stations are situated, many others on less important points of our seaboard are likely to meet a similar fate.

IN the House of Commons on Tuesday evening, Mr. Mills asked the Secretary of State for War whether any decision had been arrived at as to compensation or remuneration to Mr. Parsons for his invention in strengthening cast-iron guns, and, if not, if he could state whether it was probable that such decision would be made at an early date. Mr. Cardwell said that upon a point of considerable importance a reference had been made to the President of the Institution of Civil Engineers, whose report had only been received that morning. No delay would take place in arriving at a decision.

A DARING attempt was made early on Monday to obtain possession of about £4,700, which had been deposited in an iron chest, and placed in the paymaster's office on the main deck of her Majesty's ship "Octavia," Captain J. H. J. Alexander, C.B., lying off the southern jetty at Portsmouth. John Aickin, a marine belonging to the ship, was on duty as a sentry on the jetty when he saw two men coming out of the port on the main deck leading from the paymaster's office. They had an iron safe in their hands, and had lifted it on to the half-port, from whence he supposed they intended to lower it on to a stage. He gave an alarm and the men made off, but were pursued and captured. They are both watermen living in Portsea.

THE King of Prussia has awarded a telescope to Captain George D. Taylor, of the barque "Flying Fish," of London, in acknowledgment of his services to the crew of the Papeuburg ship "Maria" in February last; also gratuities of £5 to the second mate, and £3 to each of the four seamen who manned the boat of the "Flying Fish," by means of which the crew of the "Maria" were rescued. The "Maria," whilst on her voyage from Runcorn to Cette, became so leaky that it was deemed advisable to abandon her. In answer to her signal of distress the "Flying Fish" bore down and launched a boat manned by the second mate and the four seamen above alluded to, who, after great exertions and considerable risk, succeeded in taking the crew, seven in all, safely on board the "Flying Fish." Some days afterwards they were transferred to another vessel, which landed them at Dover.

THE National Artillery Association commence their annual competition at Shoeburyness on August 2 next, under the same rules and regulations as hitherto existed. The sum of £50 given by the National Rifle Association, which has been heretofore distributed in carbine prizes, and competed for at Wimbledon, has this year been given over to the National Artillery Association, and by the council appropriated towards great gun prizes. Artillery volunteers in general think this sum ought still to be maintained for carbine prizes, the competition for which might be carried out at Shoeburyness. It is to be hoped that some improvement will be effected this year in the *cuisine* department of the camp, and that better means of conveyance from Southend to Shoeburyness, and at a cheaper rate, will also be established.

ATTENTION has been directed to the question of the consumption of coal by our ships of war, and on Friday week, the "Lucifer," 1, paddle vessel, went out of Portsmouth harbour, and made a run outside of the Wight, for the purpose of testing some Lancashire coal. At the present time, Welsh coal is generally used, at a considerably higher cost than north country coal, which has been considered objectionable in consequence of the large quantity of smoke it produces. The experiments made on Friday week, proved, however, that by using a smoke-consuming apparatus, no more smoke is produced than from Welsh coal, and it is anticipated that the north country coal will be brought into general use, by which means a considerable reduction in the heavy item for coals is expected. Captain E. B. Rice, A.D.C. to the Queen, and superintendent of the steam reserve at Portsmouth, and Mr. George Murdoch, inspector of machinery afloat, were on board for the purpose of witnessing the result of the experiments.

Miscellanea.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending July 17, was 8,349. Total number since the opening of the Museum, free daily (May 12, 1858), 1,604,884.

A DISCOVERY was made on the 7th inst., at Herculaneum, of two gold brooches of moderate size still fastened to two pieces of stuff. They probably served as the clasp for a peplum. A small faun was also found—an indifferent copy of a very valuable original.

ON Friday, the bronze statue of Mr. George Peabody, the work of Mr. Story, the American sculptor, was placed on its granite pedestal in the enclosed small area at the north end of Exchange Buildings and Treadneedle-street, opposite the Royal Exchange. It is stated that the unveiling of the statue is to take place to-day.

ARRANGEMENTS have been made, by permission of the directors of the East London Railway, and of Mr. Hawkshaw, the engineer, for a visit of the members of the Society of Engineers to the works, on Friday, the 30th of July. Members are to meet at the Wapping shaft of the Thames Tunnel at 2 p.m., proceeding thence to New Cross.

A DESPATCH from San Francisco (June 29) says—"Successful experiments have been made in this city with a working model of an aerial navigation machine. It not only ascended into the air, but was propelled in any required direction by the machinery, and it has the capacity for carrying eight or ten persons, being constructed for the purpose of making trips to New York. The inventor is confident that the trip can be made in 24 hours."

THE number of visitors to the South Kensington Museum during the week ending July 17, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 10,707; Meyrick and other galleries, 2,303; on Wednesday, Thursday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,892; Meyrick and other galleries, 245; total, 15,147. Average of corresponding week in former years, 12,715. Total from opening of Museum, 8,624,876.

A FEW days since a thunderbolt struck Mdlle. Franconnet, aged 19, who was with her mother in the vineyard of Neuves-Maisons, Vosges, France. The young girl expired on the spot; the electric fluid, entering by the feet, furrowed all the right side of the body and came out by the chin. The unfortunate mother, who was also prostrated, was enabled to rise from the ground without serious injury, but the sudden death of her daughter appears to have affected her intellect.

DURING a storm at Strasbourg recently three soldiers were sitting on a bench under the shelter of a tree when the electric fluid fell upon them, killing one instantly, his shako and necktie being strewed about in minute fragments. The second was struck on the back of the neck, and only lived a few minutes. The third had his legs burned, but not severely. A Custom House officer, who was standing not far off, was flung down, but received no injury. His watch was, however, broken into a great number of pieces.

THE General Omnibus Company have hit upon a style of omnibus which is calculated to reduce their dividends for the summer quarter. That would be a slight matter if the health of the public also were not involved. They have succeeded in so constructing their newer omnibuses as to absorb as much heat and to exclude as much air as possible. On several days last week, the air of these omnibuses was like that of a badly ventilated Turkish bath. The new windows are fixtures—they cannot be opened; and the feeling of closeness produced by this arrangement on a hot day is intolerable. Oh! for the double-ended tramway cars.

MR. H. A. CHURCHILL, C.B., her Majesty's consul and political agent at Zanzibar, has just arrived in this country, and we are happy to hear that he speaks with confidence as to the safety of Dr. Livingstone, from whom he has had letters of a date more recent than that of his reported murder. It is Mr. Churchill's opinion that Dr. Livingstone, having heard of the discovery of the northern portion of Lake Albert Nyzanza by Sir S. Baker, has directed his route in search of the southern boundary of that lake, and that in the course of a few months it is probable that further news will be heard from Dr. Livingstone himself.

AN appalling disaster has fallen upon the usually busy and thriving town of Gefle, in Sweden. On Saturday, the 10th inst., a fire broke out in a carpenter's shop in the centre of the town, and a strong gale from the west blowing at the time, the fire spread rapidly, and in a few hours the whole of that part of the town which is situated on the north side of the river was burnt down; 700 houses and tenements were destroyed, and 8,000 houseless persons, out of a population of 13,000, having lost almost everything they possessed, are now camping i the open air. The loss is estimated at above £500,000.

THE Netherlands International Exhibition a Amsterdam was opened yesterday week by Prince Henry of the Netherlands, his Royal Highness o on arriving at the palace being received by the Ministers, the Corps Diplomatique, the civic authorities, and a number of distinguished foreign visitors invited to take part in the ceremony. There are 14 countries exhibiting, the Netherlands numbering 928; Belgium, 338; France, 308; Great Britain, 201; Austrian, 144; North Germany, 129, out of a total of 2,325 exhibitors. Mr. Thurlow, at present attached to her Majesty's Legation at the Hague, has been instructed by the Foreign Office to draw up a detailed report upon the exhibition for presentation to Parliament.

THE Marseilles journals state that a mine having been exploded in a quarry on the side of the hil Notre Dame de la Garde, an enormous mass of stone, containing not less than five cubic meters, and weighing about 15 tons, was detached, and rolled down the declivity as far as the church of St. François d'Assizes, on the Bouleuard Vauban. It broke through the wall of the sacred edifice, making a hole of five square yards in extent, and only stopped at the high altar, part of which it smashed. Happily the building was empty at the time or the consequences might have been most serious. The block was so large that it was obliged to be sawn in pieces to get it out of the church.

A PARLIAMENTARY return on the subject of the adulteration of food shows that, in the metropolitan district in the year 1866, 22 persons were convicted under the Revenue Acts of adulterating food and drink; in 1867, 7 persons; and in 1868, 5 persons. In 1866, the convictions were all for selling adulterated coffee, adulterating chicory with mustard husks, or having in possession materials for adulterating beer; in 1867 and 1868, the convictions were all for possessing or supplying materials for adulterating beer. In 1866, the penalties, as mitigated by the Board of Inland Revenue, amounted to £153; in 1867, to £97; in 1868, to £236. These cases are doubtless but a small percentage of the offences committed by adulteration of food.

DURING Sunday night and Monday storms o much violence passed over the north-east of Yorkshire, hanging chiefly to the Cleveland edge of the moors. The crops in the course have been considerably knocked down, but will recover themselves, being yet quite green. Damage in this way will be slight, particularly as most of the district is moor, and the storms did not reach the corn-growing districts, and the wolds altogether escaped. In Barkley Howl Wood, a great number of trees are demolished, a shed was fired, and a cow roasted. In Eskdale, the Egton vicarage, a new house, inhabited for the first time, was struck and damaged. The Marquis of Normanby's seat, near Sandsend, was also damaged by the lightening.

MORE than 300,000 head of cattle have been lost in Sicily by typhus. The pasturages produced nothing, and the animals remaining are insufficient for the cultivation of the corn crops. The prices of milk and meat have risen considerably, and there is a complete dearth of the latter in the centre of the island; at Palermo, it has become an article of luxury, and is sold in the markets at 1f. 25c. and 1f. 50c. a pound. The middle and lower classes have almost ceased to eat animal food, and, in a town of 200,000 inhabitants only about twenty oxen a day are killed, and a portion of those are for the use of the troops and the hospitals. Even to provide for the small consumption in Sicily, recourse has to be had to importation. Foreign breeders might therefore find a good market for their produce in that country.

ON Wednesday morning, a colliery explosion occurred in the 9ft. mine at the Queen's Colliery, Haydock, belonging to Messrs. Evans and Sons, seven miles from Wigan, at the same place where there was an explosion at the beginning of the year. One hundred colliers went down in the morning, and, after the explosion, at 11 o'clock in the forenoon, about one-half of them fought their way through the choke-damp and escaped. Forty-eight dead bodies are lying at the bottom of the shaft; one man has died since he was brought out, and the searchers are groping in the dib-hole for others who are believed to be there. A large crowd surrounds the pit, waiting for the bodies which will be brought up at dark.

IT appears by the last accounts from Australia that the advices received by the Melbourne Meat-Preserving Company respecting the sale in London of their tinned meats, had given very great satisfaction throughout the country, and that in consequence it was confidently expected the various boiling-down establishments will have factories for similarly preserving and shipping to Europe the large quantities of meat hitherto literally wasted and destroyed by the process of boiling down the stock to extract the tallow. At one establishment near Ballarat 180,000 sheep were boiled down for tallow during the past

eighteen months, and the mutton destroyed by the process is estimated at 1,800,000lb. weight, which, if preserved, might have been sold in Europe for £41,000.

THE Dominion of Canada has enacted a new patent law, which goes into operation at once. It is a ponderous statute, filling nearly four columns of the Montreal "Telegraph," but inasmuch as it excludes all non-resident alien inventors from the benefits of its provisions our inventors can feel no special interest in its full details. Section 6th provides, however, that "any person having been a resident of Canada for at least one year next before his application, and having invented or discovered any new and useful improvement not known or used by others before his invention or discovery, may obtain a patent therefor." This provision, to say the least, is one step in advance of the old law, as, under the new system, a citizen of the United States who is willing to suffer an exile of one year by summering and wintering in the Dominion may secure a patent for his invention.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—3991
BUILDINGS AND BUILDING MATERIALS—3031, 3936, 3939
CHEMISTRY AND PHOTOGRAPHY—3954, 3959, 3967
CULTIVATION OF THE SOIL, including agricultural implements and machines.—3951, 3966
ELECTRICAL APPARATUS.—3925, 3932
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3915, 3960, 3968, 3970
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—3918, 3920, 3923, 3929, 3937, 3942, 3947, 3948, 3949, 3950, 3957, 3958, 3961, 3964, 3969
GENERAL MACHINERY—3924, 3926, 3928, 3935, 3940, 3952, 3956, 3962, 3963, 3972
LIGHTING, HEATING, AND VENTILATING—3917
METALS, including apparatus for their manufacture—3930, 3944, 3965, 3971
MISCELLANEOUS—3819, 3927, 3973
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—None.
SHIPS AND BOATS, including their fittings—3916, 3933, 3938
STEAM ENGINES—3922, 3941
WARFARE—3946

3915 B. NORTON, Huddersfield. *Pile fabrics.* Dated December 22, 1868.

The inventor applies colour, or it might be lacquer, or resist or discharge, to the tips of the pile by means of circular revolving brushes. The pile fabric, whether it be a cut pile or a raised pile, is led around a portion of a circumference of a roller or drum, with the pile outwards, and whilst so supported by the roller or drum, colour or lacquer, or resist or discharge, is applied to the pile by means of the circular revolving brushes. It is preferred to employ two revolving brushes, which act in succession upon the pile surface; as the fabric is moved onwards continuously each of the brushes may be supplied with colour, lacquer, or resist by rollers from a trough, or the first brush only may be thus supplied with colour or material, and the second brush may be employed to rub it more intimately into the pile surface. Both brushes may also be made to revolve in opposite directions, as they may both revolve in the same direction, but it is preferred that they should revolve in opposite directions. In addition to the revolving brushes, other brushes may be employed, either circular revolving brushes or flat brushes, to move to and fro endwise across the piece or otherwise when the colour, lacquer, or resist is required to be worked very deeply into the pile. Any or all the rollers which supply the colour or material to the brushes may, if required, be heated by steam or by other means. The trough containing the material may also be similarly heated.—Patent completed.

3916 W. E. GEDGE, Wellington-street. *Floating docks.* (A communication.) Dated December 22, 1868.

This floating dock is composed of main supports or ribs placed in a plane perpendicular to the keel, and about 6ft. 6in. apart from axis to axis. Each of these ribs is composed of five rows of pieces of wood, placed end to end, the one above the other and breaking joint; the fall of each of these ribs is about 36in. for the straight parts. They are strengthened at the curves and above the keel; these pieces are united to each other by a number of pins of compressed wood or of iron, passing through at least three pieces, and by bolts or iron passing through all the pieces and the ceiling or foot-walling. The head of the ribs is tied by two braces bolted together. These ribs are kept apart from the interior by sixteen rows of braces, which serve at the same time to uphold the scaffoldings. The ribs may be composed of ten, fifteen, and twenty pieces, the one on the other, and breaking joint, and the pins of compressed wood or of iron should pass through at least half the thickness. Once bolted or pinned together all these pieces of wood become dependent upon each other. On these ribs is placed the ceiling or foot-walling, composed of horizontal pieces from bottom to top until under the planking of the bridge. This foot-walling is fastened on the ribs by pins of compressed wood or of iron passing through two or three rows of the pieces of wood composing the ribs. On this foot-walling is placed the frame, which is composed of two thicknesses of planks or timbers; this frame is placed obliquely; it passes all round the dock, and envelopes the foot-walling. All this combination is jointed on the entire extent of the dock, and with cross joints sloping in inverse direction. This frame is held on the ceiling by a quantity of treenails of compressed wood passing through the whole, and it rises to the bearing line of the gallery.—Patent completed.

3917 B. W. MAUGHAN, Goswell-road. *Heating water, &c.* Dated December 23, 1868.

This consists in exposing the water or other liquid intended to be heated directly to the action of heat, the liquid being submitted to the action of the applied heat while in the condition of thin streams or sheets. The water or other liquid intended to be heated is conducted through a suitable pipe, fitted if necessary with a regulating tap or valve, into the upper part of a chamber or box or any equivalent receptacle, which acts as the heating chamber. This chamber may be conveniently made of metal or other material, capable of sufficiently resisting heat, and may be covered externally with a substance that is a non-conductor of heat. The chamber is fitted internally with a diaphragm or diaphragms or their equivalents, down or along which the liquid is caused to flow in thinly divided sheets, or to trickle in numerous small streams, so as to expose a large surface of the liquid to the action of heat, and so facilitate its absorption by the liquid.—Patent completed.

3918 E. M. THORNTON, Holborn. *Footstools, &c.* Dated December 23, 1868.

This consists in adapting to, and employing in the interior of a footstool, foot cushion, or hassock, a square or other conveniently shaped vessel or receiver, constructed of metal or other suitable material, to contain boiling or hot water. The vessel or receiver is enclosed in the footstool, footcushion, or hassock, and is surmounted on all sides except the top with a non-conducting material or substance to prevent the escape of heat from the water, excepting through apertures or holes in a perforated cover, which is attached by hinges or other fastenings to the vessel or receiver.—Patent abandoned.

3919 G. M. WOLMERSHAUSEN, Mayfair. *Modelling figures.* Dated December 23, 1868.

This consists of a jointed combination of metallic bands or belts provided with clips and catch fastenings for arranging and adjusting the same to the body through the medium of perforations formed in the under slips (constituting the bands or belts) with corresponding projections on the upper ones, which are made to slide together in their position face to face, and admit of being extended or contracted to the various sizes and inequalities in the measurement of the body by the employment of sliding loops together with the spring catches aforesaid, and at the same time prevent their shifting out of place whilst being adjusted to or removed from the figure.—Patent abandoned.

3920 W. G. REEVE, Greenwich. *Inkstands.* Dated December 23, 1868.

This consists in supporting in bearings or pivots on a suitable frame a cylindrical or other shaped vessel or reservoir, for containing ink, the cylindrical reservoir or other vessel having an opening and lip in any convenient part thereof, for the admission of ink into the reservoir, and the supply of ink to the pen, and being so balanced by a weight, or acted upon by a spring, that on liberating a catch engaging in a notch or recess on the cylinder, the cylinder will by the gravity of the weight or the action of the spring turn upwards on its axis, thereby causing the opening to come in contact with a plate above the cylinder, by which means the opening is closed, the ink returned to the reservoir, the evaporation of the ink prevented, and the entrance of dust avoided.—Patent completed.

3921 G. HOOKMAN, Oxford. *Sash lines.* Dated December 23, 1868.

Instead of the ordinary sash line made of cord, the inventor uses a strip of steel, either tinned or otherwise plated to preserve it from rust, or, in addition, he binds it with wire to improve its appearance, and the better to adapt it to run on the pulleys. If bound with wire, it may be coated, in addition to or instead of the tinning, with gutta-percha or some other waterproof material, or a solution of such material, the wire covering the whole. In some cases, he uses a line of gut, similar to the small bands of lathes and other machinery. This he also binds with wire in the same manner, and for the same purpose as in the former case, and this prevents its wearing, and forms a spiral spring which does not interfere with the flexibility of the gut; or a hempen line, heated with a solution of gutta-percha or other waterproofing material, might be substituted for the gut. He fastens the above lines to the sash frames and to the weights in such a manner as to obviate the necessity of removing the sash from the window frame on each occasion of replacing a broken line; to this end, he ploughs or forms a groove along the whole length of the side of the sash frame.—Patent completed.

3922 G. LOWRY, Salford. *Ferrules.* Dated December 23, 1868.

This consists in forming a ferrule or bush of malleable iron or other suitable material with a flanch at one end; this ferrule or bush is inserted in a hole previously made in the barrel, into which the ferrule or bush has to be fixed, the said flanch coming against the stave of the barrel. An expanding mandril is then introduced inside of the ferrule, which presses or bulges out the ferrule with sufficient force to make it secure and a water-tight joint.—Patent completed.

3923 H. G. THOMPSON, New York. *Carpets.* Dated December 23, 1868.

According to this invention, when weaving the above-named fabrics, after the warp threads have been raised to the surface in such order as they are successively required to form part of the ornamental surface or design, they are woven for a short distance (one, two, three, or more picks) into the body of the fabric, and then withdrawn and cut off from the back of the fabric, the ends of such threads when again required being first woven into the body of the fabric next raised on to the surface to form the pile or figure, then again woven for one, two, three, or more picks into the fabric, and then withdrawn and again cut off from the back of the fabric. A Brussels carpet or other terry or cut pile figured fabric manufactured according to this invention will have as large a quantity of the more costly figure or ornamenting threads thrown on the surface throughout the entire length of the fabric as those heretofore manufactured, but in place of such more expensive yarns extending and being hidden from view within the body of the fabric, between the points at which they appear upon the surface of the fabric, such yarns in a fabric manufactured according to this invention are only introduced into the fabric when and so long only as they are required to form part of the terry or cut pile or other ornamental figured surface. According to the invention, a "stuffing chain" or additional warp threads are introduced, to fill up and give substance to the fabric, and take the place of the more expensive figuring or ornamenting threads which have been withdrawn.—Patent completed.

3924 J. H. JOHNSON, Lincoln's Inn-fields. *Teeth.* (A communication). Dated December 23, 1868.

This consists essentially in making the plates to which artificial teeth are secured of an elastic or springy material, and of such shape or form that whilst adapting themselves to the form of the mouth they will be held in their place when inserted in the mouth by their inherent elasticity alone without the aid of clasps or suction. This is accomplished by cutting away from plates, as ordinarily made of an elastic substance, the roof or upper part thereof having wings or spring-like arms, or by forming the plate holding the artificial teeth of an elastic strip fitting the sinuosities of the roof of the mouth at or near that part of the mouth which corresponds to the roots of the teeth.—Patent abandoned.

3925 W. E. GEDGE, Wellington-street. *Electric bell.* (A communication). Dated December 22, 1868.

This consists of a wooden box more or less ornamental holding the pile composed of a piece of gas retort charcoal dipping into a liquid coming from a glass vase or reservoir, the lower part of which extends over the entire breadth of the box, and presents a cavity in which the coal dips being immersed in an excited liquid, always maintained at the same level, although used and evaporated by contact with the air and a temperature more or less warm. This action, however, takes place but very slowly, the liquid offering but a very small surface to contact, being under the same conditions as an ordinary bottle uncorked full of liquid, and with a narrow neck dipping in a small vase of the same liquid when reversed between the reservoir and the coal. A zinc cylinder is superposed on the surface of the exciting liquid, into which it lowers and is to be immersed, and thereby constitute an electric pile acting on a combined bell-ringing or alarm-sounding apparatus and indicating board or plate. This pile may remain charged and sufficiently powerful for use during as many years as may be desired, according to the capacity of the square glass vase contained in the box. The immersion of the lower extremity of the zinc is effected by pressing on a knob communicating with the upper part of the box, and which rising again by means of a spiral spring instantly interrupts the current. The zinc is held perpendicular in a copper tube, which permits its being slightly lowered, when by long use it has lost its usual position. This pile in action for 24 hours without interruption with the striking work, and the indicator admitting that each apartment rings twenty times a day, which may be done twenty times in a minute, the pile being excited by about the 1-10th of a quart of exciting liquid, is only used 365 minutes in a year for twenty times a day, equivalent to 7,300 touches; and as there are more than three times this number in 24 hours, would be equivalent to more than three years' service. A 1-10th part of a quart of liquid would be absorbed by contact with the air during this period, but it is replaced by the reservoir.—Patent completed.

3926 F. P. WARREN, Lee. *Cooking.* Dated December 23, 1868.

The apparatus consists of a grate supported upon a box or ashpit contained in a casing, the lower part of which is formed to contain water. The boiler is made of wrought iron and has two projecting parts of peculiar form so arranged that the space between the lower parts of their inner sides constitutes a furnace or fireplace, the side walls of which are formed by the said projecting parts, and the crown of the furnace or fireplace is formed by the under surface of a boot projecting from the inner side of the projecting part, and this boot takes into a corresponding cavity or recess situated between an upper boot and a lower boot of the inner side of the projecting part of the boiler, thereby forming a peculiarly curved flue, by which the product of combustion first pass for a certain distance, horizontally in one direction, between the under side of the boot of the projecting part and the upper side of the lower boot of the projecting part of the boiler, thence upward for a short distance in a semicircular or curved direction, afterwards proceeding horizontally or nearly so for a short distance between the upper surface of the boot of the projecting part and the under side of the upper boot of the projecting part of the boiler, in a contrary direction to their first-mentioned horizontal course, and, lastly, in a vertical direction till they enter the flue, situated between the upper surfaces of the projecting parts of the boiler and the under side of the oven, from whence the products of combustion proceed to the flues or spaces, and at the sides and top of the oven, and escape into a suitable pipe or tube provided for the purpose of inducing a draught and conveying them away.—Patent completed.

3927 T. W. WILSON, Craven-street. *Hydraulic lifts.* Dated December 23, 1868.

The inventor sinks in the foreshore of the estuary of a river or other suitable locality, two parallel lines of hollow columns or hydraulic cylinders, set at such distance apart as will enable any vessel or vessels which it is desired to raise out of the water to be floated in between them. These cylinders he prefers to make of cast iron, and he determines their number, capacity, and distance apart according to circumstances or the requirements which the hydraulic apparatus is intended to meet. These cylinders will stand up out of the water any desired height, determined somewhat by the height of lift required. At their upper ends all the cylinders of each line are connected together by means of compound hollow longitudinal girders, which are fitted with transverse partitions and bottom plates, whereby a large portion of the space comprised within the hollow girders is converted into water tanks. The several tanks formed in each girder are connected together by horizontal pipes, so as to equalize the height of the water in all the tanks of the series. Each of the cylinders is provided with one of these tanks, and leading down from the horizontal pipes connected with the tanks are pendant pipes which enter the cylinders from

the top, a vertical recess or hollow rib being cast in the cylinder from end to end thereof to receive them. A sluice cock or valve is provided at or near the point of junction of the pipes with their respective pipes, for regulating the discharge of water from the tanks into the cylinders.—Patent completed.

3928 A. V. NEWTON, Chancery-lane. *Cod liver oil.* (A communication). Dated December 23, 1868.

This consists in the employment of carbonic acid gas, either in a gaseous form or in the form of a carbonated water, in combination with oils and fatty substances, the said combinations being either chemical or mechanical, or both. In order to sweeten oils and fatty substances, the rancid material is worked over into a vessel charged with either carbonic acid gas or carbonated water, and the plan of preserving these substances is to seal them up in airtight vessels charged with carbonic acid gas or carbonated water. In general, it is preferred to have a pressure of the gas within the vessel, so as to insure the contents against any possible entrance of the external air. In preserving milk it is preferred first to condense it by any known process used for this purpose, and then to charge the condensed milk with gas in a vessel completely air tight.—Patent completed.

3929 A. M. CLARK, Chancery-lane. *Gas burners.* (A communication). Dated December 23, 1868.

A burner is provided with a central air space and with a screwed stem bored for the passage of gas. The burner is cast in a single piece, and the part is connected to cone by arms, also made hollow, and uniting with the orifice for the admission of the gas. There is a cap enclosing the burner, to which it is fitted. This cap is perforated at the top, and receives the gas from arms. A socket carrying the burner screws on to the stem, or it may be made in one with the cup. The ordinary mounting of the burner, through which the air is supplied thereto, supports the gallery which holds the chimney.—Patent completed.

3930 W. H. WALLEN, West Holloway. *Copper and brass.* Dated December 24, 1868.

The object is to enable the electro deposition of copper and brass upon iron and other substances to be made with less battery power, with greater economy, and more solidly and perfectly than has hitherto been done. A solution for electro-depositing brass is made as follows:—Crystallized sulphate of zinc (1 part by weight) and crystallized nitrate of copper (2 parts) are dissolved in the smallest quantity of water that is possible. Sufficient strong ammonia water is added to precipitate, and then fully redissolve the oxides. Then the purple tint of this solution is completely removed by a standard solution of cyanide of potassium. The resulting solution should be left to stand for a day or two, and may then be worked with from one to three battery cells, using heat if a brass anode be employed. It is, however, preferred to work this solution by either of the porous cell arrangements hereinafter described, the hydrated oxides of copper and zinc being from time to time supplied, and, if necessary, ammoniuret of copper being added. Before adding the hydrated oxides, it is advantageous to add as much of the cyanides of the metals as will dissolve in the menstruum. ammonia water and a standard solution of cyanide of potassium should be added occasionally to this depositing liquid, in order to keep the salts of copper and zinc well in solution. The hydrated oxides of copper and zinc are mixed and thoroughly incorporated in the proportion of two parts by weight of the hydrated oxide of copper to one part of the hydrated oxide of zinc before they are added to the solution. During working, little or no hydrogen should be evolved from the article.—Patent completed.

3931 T. WARREN, Glasgow. *Glass furnaces.* Dated December 24, 1868.

This consists, first, in making the sides of the melting tank of solid brickwork; second, in making the furnaces with the outer parts of their roofs considerably lower than at the inner end; and, third, in forming a thin air flue under the passage or throat leading from each furnace to the tank, air being admitted to such flue from the heating flues below, and continuing on to the air inlets into the tank.—Patent completed.

3932 J. H. JOHNSON, Lincoln's Inn. *Telegraphic despatches* (A communication). Dated December 24, 1868.

It is proposed to adopt a stenographic arrangement of the letters of the alphabet, single letters being not only indicated by certain conventional signs but also such combinations of two or more letters as must frequently occur in the common words. The despatch to be transmitted is first printed upon a strip of metallized paper in non-conducting ink by the aid of type, worked by three series of keys, each series being composed of two rows containing four keys in each row. The signs which are printed by the type on the paper in transverse lines consist simply of broad and narrow square dots, used either singly or in various combinations of not more than four, and with the spaces or internals between the dots differently disposed, according to the particular letters or cominations of letters required. This printed despatch is then conveyed to the transmitting instrument, wherein tracer points are caused to traverse along each line of signs previously printed in non-conducting ink on the metallized paper, and thereby, as is well understood, direct the corresponding currents along the line wire, the message being received and recorded by the well-known Morse instrument.—Patent abandoned.

3933 W. R. LAKE, Southampton-buildings, Chancery-lane. *Carriage boats.* (A communication.) Dated December 24, 1868.

The boat has a flat bottom which is double as far as above the water line. Between the two bottoms, which are very slight and thin, and which are made of sheet metal or wood, is placed a thick bed or layer of cork, which renders the boat buoyant. In the fore part of the boat is arranged a driving shaft, which is supported upon the hull by two bearings, and which carries at its centre a crank. On the extremities of the said shaft outside the hull are placed two large wheels, which serve as driving wheels when the boat is on land. The shaft may also be provided with paddle wheels. A connecting rod is attached to the crank, the other end of the said connecting rod being jointed to a horizontal rod which rests on rails supported on small columns or standards. Small rollers attached to this rod at suitable distances apart permit the same to work without friction on the rails. Above these rollers, and through rings or eyes, are passed transverse bars which serve as handles, whereby the sailors sitting on seats provided for them can impart a reciprocating motion to the horizontal rod, and thereby turn the driving shaft.—Patent completed.

3934 C. D. ABEL, Southampton-buildings, Chancery-lane. *Rolling mills.* (A communication.) Dated December 24, 1868.

The object is to convert the sliding friction of the axles of the rolls of rolling mills in their bearings into a rolling friction, and thus to obviate almost entirely the loss of power which results under existing arrangements from the first named friction. For this purpose the rolls have gudgeons running in ordinary bearings in the headstocks, as heretofore, but these bearings do not take any of the upward and downward pressure exerted by the rolls, but only serve to steady them in their motion, the pressure being taken by the following arrangement:—At the inner side of the headstocks framing necks are formed on the rolls, the necks on the lower roller being made with V grooves, while those the upper roller are made with projecting V surfaces. The necks of the lower roller take a bearing directly upon corresponding projecting V surfaces on the inner circumferences of large strong rings or hoops, which pass round the necks of both rollers, being of such a diameter, however, that the upper roller does not bear directly upon their inner surface, but through the intervention of antifriction rollers having V grooves corresponding with the V surfaces of the upper roller and the ring.—Patent completed.

3935 H. ROBINSON, Lewisham, and J. SMITH, Carshalton. *Millstones.* Dated December 24, 1868.

This consists in dressing millstones so that the cracks or lines are made coarser or wider apart at or near the skirt or periphery of the stone than near the centre thereof. In order to carry out this invention, the inventors place in or near the eye or centre of the stone a pivot supported by a flange, which may be screwed or otherwise fastened to the said stone during the operation of dressing. Upon the pivot a hollow casting having a curved slide affixed thereto is bolted or otherwise fastened, so that the casting and its curved slide can revolve on the pivot by reason of the bolt heads running in grooves cut in the flange above mentioned, the nuts on the bolts being screwed tight when the casting and its slide are in a proper position for working; or the said grooves may be dispensed with, and a check nut used in lieu thereof.—Patent completed.

3936 R. BOBY, Bury St. Edmunds. *Floors for malt kilns, &c.* Dated December 24, 1868.

The panels composing the floor consist severally of a rectangular frame of wrought iron of about 3ft. square, fitted with rods or wires set parallel to each other, and sufficiently close to prevent the escape of wheat or other kernels between them. These rods or wires the inventor rivets to the panel frame, and he further supports them by intermediate crossbars also made fast to the frame. When applying the panels as a flooring for a kiln or drying room, he supports them on iron girders and transverse beams, carried by the walls of the building, and he thus forms a strong floor, which will effectually expose the superincumbent grain or produce to the action of the ascending currents of air. When the drying season is over, and the use of the kiln is not required, the panels may be lifted out of their place, oiled, and packed away, to prevent all unnecessary exposure, and the consequent oxidation of the metal which would take place if the panels remained in place in the kiln.—Patent completed.

3937 R. C. M. TURNBULL, Piccadilly. *Working punkahs.* Dated December 24, 1868.

This consists of a train of wheels caused to rotate by means of weights, so as to drive a flywheel to which the punkah or fan is connected by cords or otherwise, the apparatus being, when out of gear, wound by a crank handle, or otherwise, so as to raise the weights to their highest position, the apparatus is ready to act. As soon as the parts are put into gear the weights begin to descend, and in so doing drive the train of wheels and the flywheel, and thus work the punkah. In order to give a sudden movement or jerk to the punkah, which it is desirable it should receive at one portion of its travel, the inventor weights the flywheel at one part of its periphery. When this weight in its revolution passes the centre of gravity it temporarily increases the speed of the flywheel, and thus gives the necessary jerk. The inventor leads the two ordinary suspending cords from the ends of the punkah rod to a ring at the centre of the rod, and he leads the steadying cords to the same ring. The four cords can thus be readily let out or drawn in, and the punkah lowered or raised as required.—Patent completed.

3938 H. CLIFFORD, Greenwich. *Cables.* Dated December 24, 1868.

This consists in coating or serving the core with powdered silica. The silica is preferably made to adhere to yarn or tape which has been previously steeped in tar, pitch, or other suitable material, the yarn or tape being afterwards wound upon the core outside the usual serving of yarn. The core is afterwards surrounded by the usual outer covering.—Patent completed.

3939 W. H. RIDGWAY and F. W. WALKER, Hanley. *Bricks.* Dated December 24, 1868.

This relates to a peculiar method of inlaying bricks, tiles, slabs, and other articles composed of ground clay, or what is commonly called "dust." The inventors use, in addition to the ordinary plunger a loose plunger or plungers, built up of two or more parts, and placed on the surface of the dust in the mould, by which they are enabled to inlay and press up a tile or slab with the face upwards by the usual stroke of the fly press. The loose plungers are composed of two or more plates or sections perforated to any pattern, the inner plate fitting accurately into the outer one, and both being removed from the press every time a brick or tile is made. The loose plungers are made from 1-8th to about 3-8ths of an inch thick, but their thickness will depend upon the depth of the inlaid portion and strength of plate required. In a pattern of elaborate character the loose plungers are divided into several sections, each of which is manipulated separately and then adjusted together with the others, in order to be placed on the dust in the mould.—Patent completed.

3940 A. C. PILLINER and J. C. HILL, Oakfield Works, Newport. *Motive power.* Dated December 24, 1868.

The inventors obtain their object by mounting one of the wheels of their machine upon a stationary axle which is hollow and has fluid admitted to its interior. A number of slots or ports are formed in the axle, which are made fluidtight by the wheel fitting truly on to the axle, with the exception of certain passages formed in the wheel, which, as the wheel revolves, pass over the slots or ports in the axle, and so allow the issue of the fluid. The inventors usually employ wheels having eight teeth, but with only every alternate tooth adapted to make a tight joint with the casing. In this arrangement there will be four passages in the wheel, one for each quadrant of the wheel, and the passages lead through the wheel into the spaces between the teeth—Patent abandoned.

3941 G. T. BOUSFIELD, Brixton. *Steam valves.* (A communication). Dated December 24, 1868.

The first portion of the invention is designed to obviate the tendency of the water to prime or be drawn over with the escaping steam, and this is accomplished by the use of an auxiliary valve secured to the lower end of the primary valve or its stem, the auxiliary valve also serving the purpose upon failure of the spring by fracture or otherwise, of closing the lower end of the steam passage of the valve and entirely cutting off the flow of steam. In carrying out this part of the invention the inventor screws or otherwise secures to the lower end of the valve stem of the primary valve an auxiliary valve, and he also forms in the base of the steam chamber or passage of the valve an auxiliary valve seat disposed below the primary valve and valve seat or another valve, the two valves being so arranged with respect to each other and their seats that, when the primary valve is controlled and operated as designed by the valve spring, the auxiliary valve shall be and remain open, so as not to obstruct the action of the steam upon the primary and acting valve. The auxiliary valve is designed to perform two offices, first, to prevent a current of water being drawn by and with the escaping steam into the open air, upon the sudden action of the steam upon the primary valve; and, second, to act as a stop safety valve in the event of the fracture or breaking of the spring of the valve. Should the spring which serves to depress the primary valve become broken or disabled, the upward pressure of the steam upon the lower and auxiliary valve will force such valve tightly up to its seat, and by this means prevent the escape and loss of steam which would otherwise find free vent into the open air, and probably lead to fatal results.—Patent completed.

3942 W. EHRAHARDT, Birmingham. *Watches.* Dated December 24, 1868.

This relates, first, to keyless watches, that is, to watches which are wound up by the rotation of an axis passing through the pendant of the watch. The inventor arranges the mechanism for winding up the watch by means of the axis, and also for setting the fingers of the watch, in the following manner:—The inner end of the axis carries a bevelled pinion which engages with a toothed wheel working in the manner hereinafter described on one of the plates of the watch. The toothed wheel engages with a second toothed wheel, and the second toothed wheel with a third toothed wheel, all in the same plane. The third toothed wheel acts directly on the spring barrel of the watch, and is provided with a click to prevent its return motion. The axis of the first-named toothed wheel is not fixed to the bottom plate, but is stationed in a slot nearly concentric with the circumference of the said bottom plate, and the axis is capable of a slight motion in the slot; a spring bearing against the axis presses it in the direction proper to make the first-named toothed wheel engage with the second-named toothed wheel. By turning the winding axis in the proper direction the winding up of the watch is effected. When the winding axis is turned in a direction contrary to that proper to wind up the watch, the pressure of the teeth of the first-named wheel against those of the second-named wheel causes the axis of the first wheel to recede in its slot, and the teeth of the first-named wheel to escape over the teeth of second-named wheel without injury to the winding mechanism.—Patent completed.

3946 C. GORDON, Goswell-road. *Firearms.* Dated December 26, 1868.

This consists in certain improved combinations and arrangements of mechanism in the construction of breech-loading firearms in which central-fire ammunition is employed. The mechanism hereinafter described may be inserted in and carried by a shoe attached to the rear end of the barrel (a portion of which has been previously removed), or the "shoe" may be dispensed with, and a portion of the rear end of the barrel removed for the admission of the mechanism. The breech block or closer is hollow, and has two parallel vertical faces respectively coinciding with the rear end of the barrel and the face of the breech plate or tang. The breech block is attached to a longitudinal bar or spindle which is placed at the side of the breech chamber and mounted in suitable lugs or projections attached to or formed on the rear end of the barrel and the breech tang, and in which it is free to rotate when the breech block or closer is elevated or depressed. On the side opposite to the before-mentioned bar or spindle (which may be termed the "hinge spindle") is a circular bar mounted in suitable lugs or bearings attached to or formed on the breech block, and in which it is capable of rotating. This bar may be termed the "cocking bar," and on the exterior thereof is formed a V-shaped groove and also a longitudinal groove connecting the arms of the latter for the reception of the stud or pin on the discharging "block" hereinafter mentioned. The cocking of the bar is actuated by means of a lever or projection attached thereto. In the interior of the breech block is placed the discharging and percussing mechanism.—Patent abandoned.

3947 G. ELDRIDGE, Dalston, and J. SMITH, Islington *Casks.* Dated December 26, 1868.

The inventors screw into the bunghole or into the tap hole of a cask, as the case may be, a metal ring or bushing with a flange or collar upon it, which in screwing the apparatus into its place is drawn tightly up against the cask, so as to ensure a good joint. This ring or bushing is prolonged so as to form a hollow cone which projects into the cask, and the sides of the cone are perforated. Into this cone another similar cone is fitted, and is secured in its place by a screw passed into its end through a disc applied at the extremity of the first cone. When the perforations in the two cones coincide, free passage is provided for the liquid into or out of the cask, but by turning the inner cone partly round the passages are closed.—Patent abandoned.

3948 J. P. MILLS, Middlesex. *Musical instruments.* Dated December 28, 1868.

According to this improvement, when the string (whether wire or catgut) is wound up to the required pitch, the spring being confined in the plate or wood and working in the groove of the flute in the rest pin or key, cannot return, whatever the strain may be, without withdrawing the pin at the end of the spring, which, when

withdrawn, allows the pin or key to turn either way, as the pin or key in present use. The present pin or key, from its construction, begins to give or move from the moment it is wound up, there being no check.—Patent abandoned.

3949 A. S. HARINGTON, Piccadilly. *Tobacco pouch.* Dated December 28, 1868.

The exterior portion of this pouch is made of leather, skin, or similar or suitable good wearing material (pig skin being preferred, as being considered more durable than other leather). The pouch is made with gussets and an overlapping cover (also of the same material), the whole being so made to roll up into a portable form. To this cover is firmly attached a strong narrow piece or thong of the same or similar strong material, long enough to be passed two, three, or more times round the pouch, so as to secure it when closed, and either full or only partially filled, in a very simple and effective manner, without any other fastening. The inside of the pouch is formed of vulcanized india-rubber, which is firmly attached as a lining (by stitching or otherwise) to the external casing of leather or other material, and fits closely the interior of the pouch both inside the gussets and the overlapping cover.—Patent abandoned.

3950 W. R. LAKE, Southampton-buildings, Chancery-lane. *Machinery for pegging boots, &c.* (A communication). Dated December 28, 1868.

This consists in operating the driving bar by a rack and pinion, the rack being secured to the driving bar and the pinion (which is revolved by a crank) being provided with teeth on a portion only of its surface. The invention also consists in producing a positive motion of the feed lever by means of a cam, and it also consists in an improved device for adjusting the gauge to regulate the distance of the pegs from the edge of the sole. The invention furthermore consists in improved mechanism for feeding the peg wood forward into the peg tube at the required time, and in a peg tube of peculiar form, and peg holder.—Patent completed.

3951 H. YORATH, Cowbridge. *Corn, hay, &c.* Dated December 28, 1868.

The object is elevating corn, hay, and other crops, into stacks. For this purpose the inventor erects a mast by the side of the stack, and stays it suitably with ropes. Upon the mast there is a gaff with haulyards to raise and lower it. The gaff carries two pulleys, one at its outer end and the other close up to the mast. A rope passing over these pulleys descends to a third pulley at the foot of the mast, and after passing this pulley a horse is harnessed to the rope. The other end of the rope descends from the pulley at the outer end of the gaff, and is attached by a swivel to a fork resembling a hay fork, but much larger. This connection is made close up to the prongs of the fork, and to the end of its long handle a line is attached which the workman holds in his hands. The fork having been stuck into a sheaf or bundle of the crop, the horse is driven along a horse run, and so the fork with the bundle upon it is lifted, the fork, as it rises, being held by means of the hand line in such a position as to retain the bundle upon it, and the hand line also serves to guide the fork. When the fork is raised sufficiently high the hand rope is released, and the bundle dropped on to the stack. The mast is erect, in a position inclining towards the stack, so that the weight of the bundle causes the gaff to swing over the stack, when, by the hand line, it is allowed to do so. The horse is back to lower the fork, which is guided down by means of the line.—Patent completed.

3953 J. A. A. LANDER, Paris. *Engraving.* Dated December 29, 1868.

This consists in certain improved machinery for engraving letters, medallions, and other ornaments in stone or metal. The machinery consists of a table or foundation on which the machine is placed; of a sliding bed plate for adjusting in advance or backwards the plan or design to be engraved by means of the screw provided with a ratchet scale indicator which regulates the distances; of a plate for removing the plan to the right or left by means of a shaft provided with a ratchet indicator. This rod carries a movable bevel pinion which gears with another bevel pinion fixed to the screw, the bearing of which is in the plate. The two pinions having the same number of teeth, the movement given to the shaft is communicated to the screw in a convenient manner. There is a turning plate for obtaining circular movements to form radial lines, circles, small oval or variegated devices operated and controlled by a quick-threaded screw furnished with a spring rack and tooth; and there is a bracket supporting the pantograph and its apparatus for suspension and motion. This bracket rises and falls in the vertical slide by means of a screw worked by a crank, placing the pantograph at the exact height necessary for bearing on the plan to be engraved.—Patent completed.

3954 G. BROWNE, King William-street. *Manufacture o as.* (A communication). Dated December 29, 1868.

This consists in operating upon petroleum or other hydrocarbon, and some of the products derived therefrom, in novel and improved apparatus, for the purpose of producing illuminating gas. In two closed tanks the inventor places crude petroleum and benzole, separately. The tank containing the petroleum he places above the ground, and that containing the benzole below the ground, and surrounds the latter tank with water. In tank one he places a worm or steam coil, to heat the liquid in the tank; he also connects an air pump with the bottom of this tank, for forcing air thereinto. He conveys the warm vapour and carburetted air from tank one into tank two by a pipe reaching nearly to the bottom of tank two, and from the top of this tank he leads a pipe to deliver the non-condensable or permanent gas into the gas holder or gasometer.—Patent abandoned.

3956 F. A. V. MICHEL, Paris. *Printing surfaces.* Dated December 29, 1868.

The object is the production of printing surfaces from set up or composed type; also from engraved plates and surfaces bearing letters, characters, devices, or designs. For this purpose the inventor first produces by pressure from the type, engraved plate, or surface, whence the printing surface is to be obtained, a mould, matrix, cast, or impression, in unsized and damped paper, which he coats, covers, impregnates, or treats with an agent, which renders it water and acid proof, that is to say, resistant to moisture and the acids or chemicals used in the process of electrotype or electro-metallurgy. The agent which the inventor recommends for the purpose is a solution of resin or a resinous substance in alcohol or spirit of wine, preferring, in many cases, one part resin with two parts alcohol. But other proportions and ingredients may be used. The paper mould, cast, matrix or impression, after having been duly coated, impregnated, or covered, is placed in the galvanic electrotyping or electro-metallurgical bath or cell with the suitable acids or chemicals used in the electro-chemical and electro-metallurgical process, and a metallic deposit, cast, copy or shell will be obtained. To impart the required strength, evenness, and thickness to the electrotype, lead, or other ductile material is run behind the deposit, cast, copy, or shell, and made true and smooth to form a backing. The electrotype is fixed to a wood or other rigid block by nails, screws, hooks, or other fastenings. For this purpose the inventor forms round the paper mould, matrix, or impression a frame or border having a flange or projecting portion with inclined sides and with a flat rim beyond, level with the mould surface, so that a corresponding frame or border will be produced on the electro metallic deposit or copy in the electro bath, having, of course, a sunken or recessed part, with sloping sides, corresponding with the projecting part of the paper mould frame, and also a flat rim. Ridge pieces are placed on this flat part, and the molten lead is run in. The nails or other fastenings used to fix the backed plate to the wood or other block, used as a foundation, are inserted or applied so that their heads or tops are in or on the bevelled or sloping border or edge of the electro-plate, and thus do not project to or come flush with the printing surface.—Patent completed.

3957 J. GILLMAN, Wolverhampton. *Scales.* Dated December 29, 1868.

This consists of a lever with arms of unequal length, acting upon the principle of distance. The fulcrum supports the beam or lever, and on it the latter plays freely, as upon an axis. A bent arm is extended from the pillar of the fulcrum to support the long arm of the lever. The long arm is graduated into divisions by notches and figures, and there is a ball of a certain heaviness which can be slipped along the bar to any required point.—Patent abandoned.

3958 H. M. GISBORNE, West Strand. *Sewing machines.* Dated December 29, 1868.

The object is to improve the means for giving motion to sewing machines. For this purpose he employs a weight, which, by special arrangements of gearing, gives motion to a toothed pinion taking into a toothed wheel fixed on to the driving shaft of the machine, or, if desired, motion may be communicated to such driving shaft by means of pulleys and straps or bands. The weight is connected to a drum or pulley by means of a chain, cord, or band, which is wound upon such drum or pulley in any suitable manner, as will be readily understood. Upon the axis of this drum or pulley is fixed a broad internal toothed wheel, which is caused to rotate by the falling of the weight, and in so doing it gives motion to a toothed wheel carried by an arm mounted loosely upon the axis, and causes such arm to travel around the axis. This toothed wheel gives motion to a pinion, also mounted loosely on the axis, and fixed rigidly to another arm carrying another toothed wheel, which, in its rotation around the axis, also receives motion from the internal toothed wheel, but at an increased speed, and so on, there being as many pinions and arms carrying toothed wheels mounted on the axis as may be required to obtain the desired speed, the last pinion being fixed to a toothed wheel giving motion to the drum or toothed wheel by which the driving axis of the machine is driven. In order to enable the speed to be regulated as desired, the inventor employs a brush surface, which is pressed up against the periphery of a wheel by means of a screw, so as to apply such an amount of friction thereto as may be required to regulate the speed.—Patent abandoned.

3959 G. T. BOUSFIELD, Brixton. *Extracting colouring matter.* (A communication). Dated December 29, 1868.

The colouring matter of madder has hitherto been found to be practically insoluble in water. This invention is based upon the discovery that when the madder root is subjected to a temperature of about 305deg. Fah., the colouring matter becomes soluble in pure water, and can be removed from the woody fibre by successive washings with water of about that temperature, and that the colouring matter carried off by the water may be precipitated in a flocculent state from the water, the precipitation being effected by cooling down the solution from the said temperature. The invention consists, first, of the process of extracting the colouring matter of the madder root by treating it with water at a temperature of about 305deg. Fah., and then precipitating the colouring matter from the water while out of contact with the madder root. The invention consists, further, in the process of extracting the sugary and colouring matters from the madder root by dissolving the sugary matter in water at a moderate temperature, and extracting the colouring matter by treatment with water at a high temperature (say about 305deg. Fah.) and precipitating the colouring matter from the resulting liquid out of contact with the ligneous matter of the root.—Patent completed.

3960 G. SLATER, Lamb's-passage. *Plaiting cloth.* Dated December 29, 1868.

This consists chiefly in the peculiar method in which a pair of rollers are caused to operate, in combination with a folding bar or plate to feed forward the fabric and form the plaits or folds transversely in the same; and it also consists in the mechanism for giving the required motion to the various parts of the machine. The rollers are formed with suitable journals, which are fitted to turn in bearings in a vibrating or oscillating frame, whose axis or centre of motion is the axis of the lower roller, or some point below the same. The two rollers are geared together, and the lower roller is connected by suitable gearing with the driving shaft. The shaft is provided with a crank, which is connected by a rod to the vibrating frame, which is thus, by the rotation of the said driving shaft, caused to vibrate and give to the upper roller a reciprocating motion upon the lower roller, while the two rollers rotate on their axis. The folding plate is fixed in front of the vibrating frame, with its edge resting upon the lower roller, and in such a position that as the frame moves towards the plate or bar a fold of the fabric is carried over its edge. This fold is then compressed between the two rollers, and the plait thereby formed is held between the rollers while the frame moves back and carries the fabric forward far enough to form another plait.—Patent abandoned.

3961 J. MARSH, Westminster. *Corking bottles.* Dated December 29, 1868.

Instead of placing over any cork or stopper of the bottle, jar, or surface, pieces of leather or other similar substance, binding the same with string or wire, and then cutting or shaping the same into proper form, as ordinarily adopted, the inventor takes india-rubber, vulcanized or prepared, so as to be really elastic, or other suitable elastic substance, and manufactures the same into caps or covers, which, when placed on the bottles, jars, or surfaces, and over any corks or stoppers, tightly fit upon the same, that is to say, he makes them in the form of small conical or sugar loaf or other suitably-shaped caps. These caps he presses on to and over any corks or stoppers of the bottles, jars, or surfaces to be capped or covered, so as to tightly encompass the same, and prove a secure and efficient closure without the necessity of using string or wire.—Patent abandoned.

3962 R. and T. HUGHES, New Cross. *Velocipedes.* Dated December 30, 1868.

The front part of this velocipede consists of the wooden horse or seat for carrying the rider. This is placed over the front or steering wheel, which has the usual guiding bridle rising from its axle and passing upwards. It partly supports the horse, and is actuated by the hands of the rider, enabling him to turn the wheel, and with it himself and the horse in any direction. The horse is partly supported by and attached to a pair of shafts (preferably metallic), which connect it with a pair of hind or trailing wheels mounted upon an axle and supporting a seat within which one or more persons may sit. The distance between the front wheel and the horse and the hind wheels with the seat may be increased or diminished according as the shafts are made long or short, and when not in use they may be detached from each other by removing the horse from the shafts.—Patent abandoned.

3963 J. LAURIE and J. WHITTAKER, Chester. *Screwing and tapping.* Dated December 30, 1868.

This consists in applying to any practicable part of ordinary bolt and nut tapping and screwing machines, but preferably to a disc holding or attached to the chuck, a band or other mechanical contrivance acting as a brake, which, by an adjusting screw or other means, causes the part to which it is applied to remain a rigid portion of the machine, while the thread is cut on the bolt or in the nut; but should any foreign substance or any other cause intervene to prevent the thread being cut, the resistance of the brake is overcome, and the part which had before been rigid revolves with the other moving parts of the machine. The action of cutting a thread thus ceases, or the machine continues in action without those parts to which the invention is applied, and the same effect produced.—Patent abandoned.

3964 S. and W. FOX, J. REFFITT, and G. GRANGE, York. *Cutting wood, &c.* Dated December 30, 1868.

This relates, first, to constructing a machine for roughing or preparing wood to be afterwards formed into bobbins or spools. This machine consists of a suitable framework, on which is a stationary headstock with a centre point, pin, or holder, and a slidable headstock, carrying a rotary hollow spindle, on which is mounted a cutterbox, having three or more cutting tools, and another sliable headstock, carrying a spindle or pin capable of sliding in the hollow spindle, and having a centre point, pin, or holder thereon; also a rotary shaft carrying a cam or tappet mounted in this framework, formed and set to operate upon the two slidable headstocks at suitable times. The slidable spindle being pushed forward to hold the block of wood to be operated upon betwixt itself and the pin or holder of the stationary headstock, while the said cam also operates upon the headstock carrying the hollow rotary spindle and cutter box, which thereby cuts and reduces the block of wood to the proper size and form, according to the setting of the cutters, the cam also operating to return the cutter head and the slidable spindle when the block thus roughed is thereby released and another introduced to be roughed in like manner, and so on.—Patent completed.

3965 A. S. CAZALAT, Paris. *Steel.* Dated December 30, 1868.

The inventor employs a peculiar construction of continuous reverberatory furnace, which he urges with compressed hot air and superheated steam, alone or combined together, escaping under the grate by a jet or jets. Through the vault of the reverberatory furnace he makes openings, in which he places the pigs of iron to be melted vertically, their lower ends resting upon the hearth or floor of the furnace. In similar openings he also places cylinders or hollow cases containing the titaniferous or other mineral to be mixed with the cast iron. When the furnace is urged to the required heat, the pigs of cast iron run down and flow into the hearth, after which he augments the temperature of the bath of metal by jets of superheated steam or air, or both combined. The vessel containing the titaniferous mineral or other mixture becomes fused, and the several ores and metals mingle in fusion upon the hearth, from whence he draws off the fused steel into suitable moulds.—Patent abandoned.

3966 J. and A. HUTCHESON, Glasgow. *Elevators.* Dated December 30, 1868.

This consists, substantially, in the construction and use of a fixed or stationary pipe, hollow barrel, or cylinder, having a smooth-surfaced deep-threaded screw revolving within it, driven in the opposite direction, to which the screw ascends at the necessarily sufficiently higher speed within it, so as to effect the screwing, raising, or elevating of water or other liquid or semi-liquid or fluid, granular or lumpy substance, or a mixture of these, such as could easily pass into the lower end of the screw and pipe, from this lower end and level to the top of the pipe, whether it be placed vertically or at an angle, the lower end being immersed in the particular substance to be raised, and the upper end provided with a slanting spout or other convenient or equivalent means of delivery, all against the gravitating power and tendency to run down the screw, owing to the angle of the thread allowing the fluid to run down on all sides round to the lower level, and in contradistinction to the modes in use of having elevating screws with their axles lying at such an angle that the rising incline or angle of the thread really runs down to the horizon, on the side rising out of the liquid or substance, running in and down the screw by its gravitation and fluidity, and thereby rising up the screw at whatever speed the screw is turned, and rather assisted than obstructed by the revolving of the case or cylinder along with the screw.—Patent abandoned.

3967 T. F. HENLEY, Pimlico. *Gum lac, &c.* Dated December 30, 1868.

This consists in placing stick lac, or gum lac, or seed lac, either broken up or otherwise, in bags or chambers of any required shape; in placing the same between heated

metallic surfaces, to which heat may be applied by means of the circulation of steam or oils or otherwise, or the plates may be heated in an oven; and in placing the same in a press—preferably an hydraulic press. Under these circumstances the heated surfaces liquefy by convection the resinous portion of the lac material, whilst the pressure being applied causes the fluid resin to exude in a filtered state through the texture provided, leaving the colouring matter or lac dye as a residue, to be afterwards removed and ground into powder, or otherwise treated for the purposes of the dyer.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated July 12, 1869.

2103 C. F. Dunderdale, New York, U.S.A. An improved apparatus for generating hydrogen gas, and for carburetting hydrogen gas or atmospheric air for illuminating and other purposes.

Dated July 13, 1869.

2104 C. A. C. de G. de Lianeourt, Queen's-road, Da'ston, Middlesex. Improvements in life belts.

2105 C. Chapman, Salford, Lancashire. Improvements in the application of pumps to artesian wells.

2106 J. Piret, Boulevard Bonne Nouvelle, Paris. Improvements in the slide valves of steam engines and elastic power engines generally.

2107 T. Restell, Birmingham. Improvements in breech-loading arms and cartridges, and a pouch or cartridge-holder.

2108 C. P. E. Roche, Rue Sainte Appoline, Paris. Improvements in the conversion of cast iron into a metal having a steelified nature, or forgeable steel.

2109 W. P. Bain, Poplar, Middlesex. Improvements in sails for ships and vessels.

2110 F. J. Smith and L. J. Abbot, East Dereham, Norfolk. Improvements in effervescing and aerated drinks and waters.

2111 R. Craig, New Battle Mills, Dalkeith, Mid Lothian. Improvements in machinery or apparatus for paper making.

2112 A. V. Newton, Chancery-lane. Improvements in mowing and reaping machines.

2113 R. Whitaker, Birmingham. Improvements in tee-totums.

2114 S. E. Crispe and J. West, High-street, Poplar, Middlesex. Improvements in apparatus for heating by means of steam.

2115 J. Barnett, Minories, City. Improvements in breech-loading firearms.

Dated July 14, 1869.

2116 I. Baggs, High Holborn, Middlesex. Improvements in the generation and treatment of ammonia.

2117 C. Shether, Edmund-place, Aldersgate-street, City. A duplicate lock or fastening.

2118 J. A. Horlick, British Hotel, Cockspur-street, Middlesex. Improvements in the construction of piano-forte hammers.

2119 J. A. Horlick, British Hotel, Cockspur-street, Middlesex. Improvements in the construction of piano-forte bridges.

2120 T. Richards, Wincanton, Somersetshire. Improvements in stoves or fireplaces.

2121 R. Willcox, Kingston, Dublin. Improvements in appliances or instruments for finding and for picking up submarine cables, and apparatus connected therewith.

2122 M. Jack, Crammond, Mid Lothian. An improved agricultural implement.

2123 J. W. Reid, Great Western-terrace, Bayswater, Middlesex. Improvements in beating engines employed in the manufacture of paper.

2124 J. Leetch, Broadley-terrace, Blandford-square, Middlesex. An improved self-adjusting spring stopper for closing the mouthpiece of speaking tubes and bottles, and for other like purposes.

2125 J. Leetch, Broadley-terrace, Blandford-square, Middlesex. Improvements in apparatus for effecting communication between the different parts of a railway train in motion.

Dated July 15, 1868.

2126 V. Coine, Boulevard Bonne Nouvelle, Paris. A vertical aero-hydraulic engine with a double action.

2127 J. Crowther, Blackburn. Improvements in the construction of the seats of railway carriages, so as to lessen the force of concussion when trains meet or run into each other.

2128 J. Crowther, Blackburn. Improvements in working hoists.

2129 J. Crowther, Blackburn. Improvements in velocipedes.

2130 J. and J. Leeming, Bradford, Yorkshire. Improvements in looms for weaving.

2131 G. Lowry, Bury-street Foundry, Salford, Lancashire. Improvements in machinery for dressing and preparing flax for spinning.

2132 W. W. H. Smith, Birmingham. New or improved machinery to be used in the manufacture of upper leathers for boots and shoes, and other articles made wholly or mainly of leather.

2133 B. J. B. Mills, Southampton-buildings, Chancery-lane. An improved process and apparatus for annealing metals.

2134 A. Adamsz, Hoxton, Middlesex. Improvements in cigarettes.

2135 C. de Bergue, Strand. Improvements in locomotives and other railway carriages.

2136 J. J. Cousins, Allerton Park, Chapel Allerton, near Leeds. Improved apparatus for indicating the points made, and registering the number of games played, at billiards and other games of skill.

2137 J. T. A. Mallet, Boulevart St. Martin, Paris. A new and improved mode of, and apparatus for, charging atmospheric air with oxygen.

2138 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in coiled springs, and in the machinery employed for making the same.

2139 J. T. Way, Russell-road, Kensington. Improvements in the manufacture of hydrochloric acid.

2140 J. Bernard, Salisbury-street, Strand. Improvements in smelting, and in furnaces, machinery, and apparatus connected therewith.

2141 J. H. Johnson, Lincoln's Inn-fields. Improvements in agricultural implements.

2142 J. Bernard, Salisbury-street, Strand. Improvements in the obtaining and utilizing heat in the operation of smelting.

Dated July 16, 1869.

2143 J. E. Millar, Sowerby, Halifax. Improvements in machinery or apparatus for raising the nap of woollen cloth.

2144 W. Hosack, Edinburgh. Improvements in evaporating liquids, and in the means or apparatus employed therefor.

2145 W. Hosack, Edinburgh. Improved ship or vessel specially applicable for rapid transit on water.

2146 J. Grint, Battersea, Surrey. Improvements in circular saw benches.

2147 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in propelling machinery for canal boats and other vessels.

2148 R. P. Williams, Great George-street, Westminster. Improvements in railway crossings.

2149 J. W. Ormiston, Shott's Iron Works, Lanarkshire. Improvements in the construction of blast furnaces.

2150 G. Yates, Heaton Norris, Lancashire, and J. R. Williams, Bowden, Chester. An improved apparatus for opening and closing the lights of cucumber and other frames, so as to give air, and for actuating and regulating the ventilators in hothouses, and in other places where it is necessary to maintain an even temperature.

2151 F. G. Fleury, Merrick-square, Southwark, Surrey. Improvements in apparatus for drawing or raising and forcing liquids.

2152 R. B. Evered, Drury-lane, Middlesex, and R. Hurst, High Holborn, Middlesex. Improvements in apparatus for raising, forcing, and regulating the flow of water.

2153 A. Rollason, Pembroke-road, Clifton, Bristol. Improvements in the mode of extracting ammonia, purifying gas liquor, and utilizing the same.

Dated July 17, 1869.

2154 B. Russ, Lime-street, City. Improvements in bicycles, velocipedes, and manumotive carriages.

2155 P. Murray, Chancery-lane. Improvements in rocking firebars for steam boiler and other furnaces.

2156 W. Pidding, Walcot-square, Lambeth, Surrey. Improvements in the mode or modes of the production or manufacture of cut piled mosaic, mosaic, textile, and tesselated fabrics, in the treatment of materials used, and in machinery and apparatus used for the said purpose.

2157 H. Mege, Paris, Boulevart de Strasbourg. The preparation and production of certain animal fatty bodies.

2158 E. F. Jones, Middlesborough-on-Tees. Improvements in machinery for making nails, spikes, and like articles.

2159 H. E. Newton, Chancery-lane. Improvements in breech-loading firearms.

2160 H. E. Newton, Chancery-lane. Improvements in electro-magnetic machines.

2161 A. Simpson, Chiswell-street, Middlesex. Improved apparatus for cleaning knives.

2162 M. Eyth, Steam Plough Works, Leeds. Improvements in carrying the steering or other road wheels of implements, traction engines, or other machines adapted for moving over common roads or fields.

2163 D. N. Defries, Metropolitan Works, Euston-road, Middlesex. Improvements in gas meters.

2164 A. Ancion, Liege, Belgium. Improvements in breech-loading firearms.

2165 C. Hook, Bridgewater, Somersetshire. Improvements in velocipedes.

2166 J. H. Johnson, Lincoln's Inn-fields. Improvements in blasting, and in the apparatus or means employed therein.

2167 C. J. Harcourt, Dozells, Aston Manor, near Birmingham. Improvements in axle pulleys for suspending window sashes, and for other like purposes.

2168 J. Bernstein, Bethnal-green. Improvements in the manufacture of umbrella, parasol, and walking-stick handles.

2169 W. Furness, New-street, Borough-road, Surrey. Improvements in cutting files and rasps and in the machinery to be employed therein.

2170 J. H. Johnson, Lincoln's Inn-fields. Improvements in sewing machines.

2171 J. Imray and G. G. M. Hardingham, Great George-street, Westminster. Improvements in sewing machines.

2172 B. Looker, Kingston-on-Thames, Surrey. The construction of an improved earthenware box or pan for growing, raising, or forcing seeds, plants, or cuttings.

2173 W. Leftwich, Tufnell Park, West Holloway, Middlesex. Improvements in the construction of velocipedes.

2174 W. Macgeorge, Castle-court, Birchin-lane, London, and A. Bigg, jun., Chester. Improved mechanism for starting and working steam engines, partly applicable to other purposes.

2175 R. Neale, Brooklyn, New York, U.S.A. An improvement in transfer engraving.

2176 W. E. Gedge, Wellington-street, Strand. An improved method of and apparatus for generating steam.

2177 A. M. Clark, Chancery-lane. Improvements in cables for the transmission of electric currents.

2178 R. Schoelesser and J. Irving, Manchester. A new process of converting wood shavings, flax, tow, hemp, jute, esparto grass, straw, hay, and other materials of a fibrous nature into paper pulp.

2179 V. E. Mauger, The Temple, Liverpool. An improved blotter or ink absorber.

2180 B. Hunt, Serle-street, Lincoln's Inn. Improvements in looms for weaving.

2181 R. Duerre, Chelsea. An improved lever manumotive apparatus.

2182 J. B. Fondu, of Braine-le-Comte, Belgium. A new and improved process and compound for blowing glass and for the apparatus connected therewith.

2183 T. Thomas, Bridge End, Cardigan, Pembrokeshire. Improvements in mills for grinding and crushing corn or other grain.

2184 W. Williams, Edinburgh Veterinary College. An elastic horse boot.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

1861 W. Thompson
1863 G. Plant
1874 N. Salamon
1915 G. Mountford and G. L. Loversidge
1936 G. B. Woodruff
1979 W. Beaumont and W. M'Master
2146 J. Whitworth
2325 E. Fitzhenry

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2027 R. Ridley and J. G. Jones
2067 C. A. Day and T. Summers
2042 R. Dunn
2060 R. Barrett
2088 T. King
2096 A. Vignon

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," July 20, 1869.

669 F. Windhausen
677 R. Badger
680 A. Morrall
687 J. A. M'Elroy
695 H. Tylor
729 W. Walker
732 W. Weldon
743 W. Wells
744 G. Glover
750 W. E. Newton
754 H. Ormson
755 J. M. Napier
769 C. E. Brooman
770 L. Labadie
774 W. H. Harfield
778 E. W. and M. Slade
780 C. Vero
782 W. T. Carpenter
784 J. Tenwick
789 C. D. Abel
798 W. M'Adam and S. Schuman
804 J. L. Norton
818 J. H. Bennett
822 G. R. Mather
825 J. H. Johnson
837 F. W. Fox
855 J. Kay
889 J. B. Fell
907 J. R. Baillie
954 A. Barclay
994 W. Allan
1027 W. Jones and T. Sheffield
1070 J. Pattinson
1335 J. R. Jefferies
1358 B. Hunt
1443 B. J. B. Mills
1557 Z. E. Coffin
1593 W. Mitchell
1804 W. E. Newton
1899 W. R. Lake
1939 C. Cochrane
1948 W. H. Perkin
1964 H. Yates
2004 W. A. Biddell and J. Redgrave
2009 P. G. Gardiner
2036 L. and L. Clayton and J. Smith
2048 F. Trappes
2103 C. F. Dunderdale

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 16, 1869.

157 P. Oldfield
165 H. and J. Parnall
167 S. G. Archibald
169 G. Lowry
170 W. and J. Pain
172 J. Armstrong
178 J. Siddeley and F. N. Mackay
179 F. A. Paget
184 P. C. Evans and H. J. H. King
199 W. R. Lake
210 W. E. Gedge
213 J. Beattie
217 W. Huggins and H. Horsnaill
215 J. Ortton
233 R. J. Green
259 J. Silman
277 W. M'Lean
287 F. Jay

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE
MECHANICS' MAGAZINE.

LONDON: FRIDAY, JULY 30, 1869.

THE COURT OF CHANCERY AND SEWAGE WORKS.

EVERY Act of Parliament tends to prove that "law begets law." It appears to be beyond the power of our legislators to frame an Act that shall be "self executing," and the birth of every fresh offspring of St. Stephen's, duly baptised with the comprehensive name of "Victoria, by the grace of God," must be hailed with delight by the gentlemen of the long robes. Some years ago, legislation was brought to bear vigorously upon the sewerage and drainage of our towns, and, in fact, upon all matters intimately connected with the sanitary welfare of our ever increasing population. Ever since the authorities took up the question, not a session has passed without witnessing some increase of the already existing regulations bearing upon it. The pollution of rivers, streams, and watercourses, by the discharge of sewage matter into their channels, has been expressly forbidden, and yet we have recently a couple of instances where it has been necessary to apply to the Court of Chancery to have the law enforced. Surely, it appears somewhat of a farce to be compelled to apply to the law to enforce its own provisions. If sewage and other refuse prohibited by an Act of Parliament is discharged into a stream, it does not require all the roundabout proceedings of a chancery suit to discover the fact and apply the remedy. No wonder that local boards and ratepayers complain of the infliction of sewage works, when their commencement is attended with heavy legal expenses which might be altogether dispensed with. If local authorities are to be saddled with the costs of a chancery suit or other legal process before they lay a drain or sewer of proposed works, our national progress in sanitary reform will be rather slow. It is true, that by its own proceedings a local board may draw down upon itself a serious responsibility in the matter of expenditure, as has happened frequently; but the question is whether it is just to the ratepayers that such should be the case. If the authorities of a town wilfully violate a law, the aggrieved parties should have some shorter and quicker remedy against them, than entailing upon the unfortunate ratepayers the onus of a chancery suit. However willing the corporate bodies of a place may be to carry out their duties and avail themselves of the advantages of sewage irrigation, it is by no means an easy task for them to do so. The Legislature has certainly provided some facilities for enabling them to execute sewage irrigation works, but there are so many obstacles in their way that they are in the position of a person whose friend has pointed out the road for him, but has previously dug a plentiful supply of pitfalls in it for his benefit.

Recently, the corporation of Halifax and the local board of Merthyr Tydvil have been in the same boat. While hard at work in endeavouring to "get rid of their sewage," instead of adopting the only safe method of dealing with it—by irrigation—they were altogether oblivious of the legal maxim

Sic utere tuo, ut alienum non lædas.

Reckless of what the consequences might be to others, they both discharged their sewage into the nearest watercourse. The former party polluted the Hebble, and the latter poisoned the Taff, inflicting, in the one instance, a serious nuisance upon large collieries, and, in the other, upon the whole establishment and inhabitants of an extensive worsted manufactory. If we consider the case of the Merthyr Tydvil people, it appears that nearly a year ago an injunction was granted against them, and yet the authorities persisted in the same course notwithstanding. The law is evidently here defective. It is absurd to grant an injunction to restrain evil doers, and subsequently take no measures to insure its enforcement. Virtually, the injunction becomes a farce, unless some private parties who are injured by the nuisance appeal to have it executed. At the same time, a reasonable period should be allowed after the issuing of an injunction, before it be stringently enforced, as in many instances it would be absolutely impossible to carry out its provisions in a summary manner. This is particularly the case where local boards are concerned, as may be readily perceived. A certain watercourse has been used from time immemorial, for the reception of the town sewage, and no one perhaps ever gives a thought to the discharge of it anywhere else. As their fathers did, so do they, and so they would continue to do, in spite of all consequences, but for the legislative enactment forbidding the continuance of such a system. Thus it happens, in the majority of cases, that when an injunction is granted, closing the only outlet a place has had for the disposal of its sewage and drainage, the authorities are completely "at sea." It has probably never occurred to a single member on the Board, that the time must come when some other means must be adopted for draining the town, and, therefore, naturally, it is in a dilemma. But it should at least make a vigorous effort to emerge from its usual lethargic state. The authorities should as speedily as possible determine upon some definite course of action, and set vigorously to work to remedy the many abuses that must inevitably attend a persistence in the old system of sewage and drainage. Instead, however, of acting in this manner, the Merthyr people have allowed matters to remain *in statu quo*, alleging that they cannot obtain the land necessary for utilizing the sewage by the only correct system, namely, that of surface irrigation. There may be a good deal of truth in this statement, and it is here where the legislation is defective respecting sewage regulations. It is true, that it confers upon a local board powers of compulsory purchase of land for the purpose of sewage irrigation, but it by no means follows that the powers can always be exercised in its favour. One or two instances where it has been sought by the authorities to put these powers into operation have failed completely, although there was no doubt of the eligibility of the land in question, with respect to position and other advantages of a local nature. Before sewage irrigation can be thoroughly carried out, greater facilities must be afforded for the acquisition of the necessary land. It is idle to say to the local authorities of a town, "You must no longer discharge your sewage into the river, you must dispose of it in some other manner," and then to practically bar the only remaining avenue for so disposing of it.

Proceeding to the Halifax case, it is interesting to notice the defence set up. It consisted partly of the assertion that the plaintiffs, as actual members of the council, had not only assented to the poisoning of the stream, the Hebble, but had even by their own decisions contributed to that circumstance. The Vice-Chancellor, however, looked at the question in a broad light, as a public nuisance, no matter how, or by whom it might have been created, and granted an injunction against the town council. It is quite time that a stop should be put to such pleas, as a denial of the nuisance in a case where it is beyond doubt that the sewage of a town is discharged into the nearest river or stream. The committal of such an act must be a nuisance, and the sooner it is understood that it will be recognized and treated as such by the Legislature the better. There is no need of any evidence respecting the magnitude of the alleged nuisance, or of any defence whatever. Let it be once shown that the sewage of a town is discharged into a river, and the single fact ought to be sufficient to establish the case and obtain the requisite injunction. The large increase of the population of most of our manufacturing towns has considerably contributed to hasten the crisis with respect to the compulsory disposal of sewage by other means than those formerly employed. The purifying action of a large volume of water, together with the influence of the atmosphere, exercises a certain amount of neutralizing effect upon sewage matter, and thus it is that where a small quantity of it is discharged into a considerable volume of water, it is exceedingly difficult to trace it at some distance down the stream. But the question assumes another aspect when the proportion of the sewage is large compared with that of the water into which it flows, more especially when it is permitted to semi-stagnate for weeks and weeks, forming a daily augmenting evil. In summer time, many of our small streams, which are at present the receptacles of the drainage and sewage of the houses in the neighbourhood, have scarcely, in some parts of their channel, 12in. of water, and yet the drainage can be seen trickling into them, and constituting accumulations which are neither slow in their formation nor their consequences.

THE FRENCH ATLANTIC CABLE.

SINCE our last notes of the above cable appeared, the work has been brought to a completion, and Europe is now united to America by three submarine cables, and communication has been freely carried on by the new route. Our latest account stated that 545 nautical miles had been payed out of the St. Pierre and Duxbury section. Since then, the work proceeded steadily onward until the "Scanderia" had payed the whole of her cable; the submerging was then continued from the "Chiltern" until 2 p.m. on the 23rd, when they anchored off Duxbury, and prepared to land the shore end, which was successfully accomplished at 5 p.m. The tests were perfect, and the cable at once taken over by the engineers of the company; the total amount of cable payed out being 749 miles. Everything throughout this trip appears to have gone on in the most satisfactory manner, the paying out being easy and uninterrupted—no faults, the insulation being throughout perfect.

The satisfactory state of the whole cable may be shown from the fact that on Sunday last the two sections of the cable were joined together at St. Pierre, and direct communication established between Brest and Duxbury, a distance of over 3,330 nautical miles. Sir William Thomson telegraphs: "During five hours to-day we have made experiments, in the course of which minute directions given from one end have been instantaneously executed at the other."

The following extract from a private communication is full of interest, as conveying a notion of some of the risks of submarine telegraphy:—

The end of the cable is hanging to a buoy somewhere near here. We have successfully laid our section. There have been four faults found, and cut out. All but one were quietly hauled in astern. One occurred when it was blowing a gale of wind. As the sea heaved the ship about, of course a greater strain was put on the cable. Three seas struck her in succession, each one breaking over the stern, deluging the decks with water, carrying several men off their feet into the scuppers. Some of the staging and bulwarks astern were smashed, and the cable parted. The end, fortunately, fouled in the paying-out-drum, and thus they had time to put on the "stoppers," which are ropes held round the cable, and always ready to be pulled tight in case of need. It was useless trying to haul in again, so we made the buoy rope fast and let go. Then, to mark the

spot, we let another buoy go, anchored to a "mushroom," with 2,030 fathoms of rope. The "Scandaria" did the same. All day and night and the next day we dodged about these buoys. When the sea went down we got the buoys in, hauled the cable up, cut out the fault, joined up, and went ahead again. The sea was most magnificent, and our ship behaved splendidly. The other two were deluged fore and aft, and tossed about like corks, while we simply rolled in a slow, deliberate, magnificent manner, though we sometimes made a tremendous angle and pitched a little. Yesterday was a miserable Sunday—thick fog, which soaks everything and drips from every rope and spar. No service, and everyone anxious and uncomfortable generally. While we were at dinner it was calculated that we ought to have reached the spot where we should meet the "Cory," so guns were fired. Suddenly the fog lifted, and there she was right ahead. She and a surveying boat had come out to pilot us between the banks. The fog was so thick that you would scarcely have found your way on land, and here we had come across the Atlantic and found exactly the right place.

In an early number, on receipt of accurate details, we trust to bring the history of the submersion of the French Atlantic cable to a conclusion.

THE ROYAL AGRICULTURAL SOCIETY'S SHOW AT MANCHESTER.

SECOND NOTICE.

IN resuming our notice of the very successful exhibition at Manchester which closed on Saturday last, we will first take the stand of Messrs. Amies, Barford, and Co., of Peterborough. Here we found a very large number of exhibits of the class usually shown by this firm. There was no great feature of novelty, but there was the special recommendation of sound principle and construction throughout. We were especially pleased with their combined hay, corn, and straw elevator, which delivers to a height of 30ft. It is worked from the steam thrashing machine, but, in hay time and harvest, the body is raised so that a horse can be worked underneath within its own length. We would also call attention to the Peterborough Gas Boiler, as patented and manufactured by this firm. It is designed to meet the requirements of all who use gas for heating purposes. The boiler is constructed upon an entirely new principle, the body being made wholly of copper, enclosed in an ornamental iron casing, and the water spaces are so arranged that a complete and perfect combustion of gas is secured, and no danger whatever can arise either to health or to plants. Experiments show that a saving of at least 40 per cent. over any similar apparatus is effected. The boilers can be placed either inside or outside a greenhouse, or in a hall or similar situation, without danger, and require no brickwork for fixing. This firm have also an excellent annular boiler of novel construction for agricultural and other purposes. The firebox being entirely surrounded by water, a saving of 50 per cent. in the consumption of fuel is effected; and, being complete in itself, can be removed at pleasure to any building where it may be required. It is valuable to the farmer for the purpose of boiling water, steeping linseed, corn, &c.; and, in a steamer which fits on the top, potatoes and other roots may be expeditiously and cheaply cooked.

Mr. Edward Gray, of the Moscow Works, Mowbray-street, Sheffield, made a splendid show of agricultural cutlery of every kind, into which he has introduced several notable improvements. To individualize the items at this stand would be to write a decent sized catalogue, whilst a classified description would occupy about three columns of our space. We, therefore, take the leading features of Mr. Gray's exhibits, foremost amongst which and perhaps most generally attractive were his steel-faced grooved horse shoes. The under side or face of the shoe is made with serrations, the shoe being made from steel or steel-faced bars manufactured by Mr. Gray for this special purpose. This is a very important invention, and one that has long been wanted, as it will enable horses to obtain a firm foothold, and prevent them slipping or falling, which is of daily occurence in London and other large cities and towns. Shoes made from this material will not require sharpening in winter, and will be found of universal advantage on the road or in the field; they are one-third lighter, and from the nature of the material will last longer than any other shoes. Crucible cast steel appears to be Mr. Gray's great material, and of this were made most of the implements exhibited. For instance, there were cast-steel fingers for mowing and reaping machines, which will keep sharp at the points and cutting part much longer than any other kinds. Then there were a variety of crucible cast-steel plough shares, coulters, and breasts, as well as a variety of machine knives, cutters, and blades of every kind. Mr. Gray had also some samples of steel-faced rails, which appeared to meet the requirements of the times as regards economy and durability. We likewise noticed a splendid pair of rag engine plates and a roller bar, as well as some steel beating bars for thrashing machines. On the whole, we were very pleased with this exhibition of Sheffield ware, which was highly creditable to the exhibitor, and well worthy of the occasion.

Messrs. Hayward, Tyler, and Co., of Upper Whitecross-street, London, had a variety of interesting exhibits. First, there was Mortlock's millstone dressing and levelling machine, of which Mr. J. L. Norton, of Abyssinian pump notoriety, is sole licensee. This apparatus is very simple in construction, the diamond being the cutting agent. One of its recommendations is the rapidity and cheapness with which a stone can be dressed, as one man can dress a stone in about an hour; only one hand is required to work it, no gearing or motive power of any kind being necessary. It is also very portable, and no fixing is required, so that the dressing may be commenced immediately the machine is placed upon the millstone. A novelty at this stand was Redup and Brigg's shive cutting machine for brewers. It cuts and finishes the shives at one operation, and makes them more rapidly than any other method. It uses up every waste piece of wood, and can be managed by a boy. This firm also exhibited their universal steam pump, which was recently described and illustrated by us. They had also a well-arranged portable pump for irrigation purposes, to be worked either by horses or bullocks. This pump is very compact, and insures the greatest amount of water thrown. The gearing is about 20 to 1; and, as the bullocks travel at the rate of about two and a-half turns per minute, the pump will work at 50 strokes a minute. The pump is the well-known 6-inch California double-acting pump—one of the simplest, or perhaps the simplest and best, of its kind, and well suited for places where no skilled labour can be had, as the valves are very easily got at, are of the plainest construction, and most effective. The pump and its gearing are fixed to a light but strong cast-iron bedplate, which again is bolted to a wooden frame, which carries the front axle (with a simple locking gear and drag handle), and the hind axle with their cast-iron travelling wheels. This pump, worked by a pair of bullocks, will draw water 30ft., and force it 20ft. at the rate of upwards of 4,000 gallons per hour. In steam engines, this firm were well represented; especially so by a 2-horse power horizontal high pressure engine, which was priced at a remarkably low figure considering the completeness of the equipment and the character of the work.

At the stand of Messrs. Burney and Co., of Millwall, we found a variety of cisterns, cattle troughs, corn bins, &c., in wrought iron, and a very good petroleum store. The cattle troughs have a patent safety undamageable edge, which is produced by riveting a rolled iron moulding around the edges of the utensils. The petroleum store is made with a magazine of sand on the top to ensure safety.

In water filters, we have first the well-known pure charcoal block cistern filter of Messrs. Atkins and Co., of Fleet-street, London. The peculiar property possessed by block carbon renders it superior to any other substance with which we are acquainted as a filtering medium. The mode by which it acts is to induce a chemical change in the noxious compounds given off by decomposing organic matter, with which water is more or less contaminated, as well as to destroy any injurious gases that may have been absorbed from the atmosphere. It is an established fact in science that there can be no motion without an active principle; hence the absorption of oxygen into the pores of the carbon necessarily involves the evolution of hydrogen, changing the polarity of the constituent particles of vapour held in solution by the water during its gravitating process, and giving off carbonic acid gas. Whenever, therefore, the impurities in water pass within the pores of the carbon, they are neutralized by oxidizing action, the change in the carbon disinfecting the water, not by mere mechanical separation, but by actual nascent combustion.

A very rapid and effective form of filter was exhibited by Mr. George Cheavin, of Boston, Lincolnshire. It is composed of charcoal and sponge, the latter material acting as a mechanical strainer. The filter can be cleaned by the user without being taken apart, a tube being provided, on blowing through which the charcoal is cleansed. These filters purify any kind of water with rapidity and certainty, effectually removing lead, lime, sewage, and animalculæ. Their especial advantages are rapidity of action, durability, and their self-cleansing properties.

Messrs. H. R. Marsden and Co., of Meadow-lane, Leeds, were busily at work with Blake's stone-breaking machine for road making purposes, and an improved stone or ore crushing machine. The rate at which Mr. Marsden was breaking up granite rendered it very probable that the Corporation of Manchester would find a large quantity of material ready to hand for road mending purposes at the close of the Show. It is unnecessary to state that these machines worked most efficiently.

Archer's stone breaker was also in full operation, doing very good work. In this machine a revolving motion is imparted to the grinding or pulverizing roller, and at the same time a short and powerful reciprocating motion is imparted to the lever with the squeezer on its end, thereby operating with a crushing action on the material between the roller and the squeezer as they are carried round by the turning of the roller. The relative distances of the operating faces from the roller are adjusted as required by varying the thickness of the liner in the connecting link. The periphery of the roller is fluted horizontally, and the faces of the operating lever are fluted vertically. The sizes of these flutes vary according to the material to be operated on, and the size required to be broken. This machine is manufactured and was exhibited by the Dunston Engine Works Company, Gateshead-upon-Tyne.

Messrs. J. and H. Gwynne, of the Hammersmith Iron Works, London, exhibited an excellent selection of centrifugal pumping engines upon their well known principle. We specially noticed their pumps, No. 2 and No. 8. No. 2 is fixed on a deep and strong bedplate, which dispenses almost entirely with foundation. The pump is capable of discharging 80 gallons per minute 80ft. high; the whole of the working parts are in steel, tempered in oil, and of the best material and workmanship. Pump No. 8 is capable of discharging 800 gallons per minute, 25ft high, or 1,500 gallons 15ft. high per minute; the engine works direct on to the pump shaft, dispensing with all gearing or belts; the working

parts are all in steel. The pump is suitable for irrigation, drainage, &c. This firm have recently introduced a new feature in their manufacture—that of Schiele's turbine, which gives a very high useful effect, and is exceedingly simple in construction.

An excellent show of wood-working machinery was made by Messrs. Charles Powis and Co., of the Cyclops Works, Millwall, London. First, there was a general joiner, which has been improved in several respects by Messrs. Powis. It has a self-acting feed for moulding, planing, &c., and will plane stuff up to 10in. in width and 4in. in thickness. The drunken saw here is also very effectively arranged. The trying-up machine is remarkably solid in construction, the frame, which is 18ft. in length, being cast in one piece. This machine will plane warped or twisted timber up to 21in. wide by 12in. deep, and 12ft. long. The cutter block and spindle are forged in one, the block being of an improved form. The self-acting saw bench exhibited by this firm was also worthy of notice. It is adapted for cutting planks, deals, and battens, at speeds varying from 15ft. to 20ft. per minute. The saw spindle is made of the best scrap iron, and runs in long gun metal bearings, the outer end of which is supported by an outside standard. A self-acting feed motion is attached, specially designed with a view to economy in space and efficiency in working. The fence can be set at an angle for cutting feather-edge boards, and always maintains a parallel position with the saw, whatever be the angle at which it may be placed. If the bench be required for cross cutting, the fence can be removed with very little trouble. The framing and table top being cast in one piece, great strength, combined with portability, is obtained. No brickwork foundation is required, its own weight being sufficient to keep it steady while working. Various other machines of this class were exhibited by Messrs. Powis and Co., all of them of the most improved design and the best manufacture.

Considerable interest was taken by the public in the Abyssinian tube well, various examples of which were exhibited by Mr. J. L. Norton, of Belle Sauvage-yard, Ludgate-hill, London. At various periods throughout each day these wells were sunk, water pumped, and the tube withdrawn in a very brief period. One of these tube wells—the true Abyssinian, 1¼in. diameter—was driven down 9ft., water was pumped, and the pump withdrawn in ten minutes. These operations were superintended by Mr. C. S. Taylor, City-buildings, Corporation-street, Manchester, the sole licensee for Cheshire, and Mr. G. F. Cox, of the same address, and who is sole licensee for Lancashire. These wells have taken silver medals at all the agricultural shows where they have been shown, including the Royal at Leicester, 1868; Middleton, 1867; Ulverston, 1868; and Southport, 1868. They can now be fixed in any strata, or almost at any depth, by a new system of boring, along with deep well pumps.

No small attraction to visitors was what the inventor terms "the biggest sewing machine out." This was a multiple needle sewing machine for making thatching, by Mr. G. O. Gooday, of Great Leighs, Chelmsford. The principal novelty in this machine, which is applicable to many purposes besides the manufacture of thatch, consists in the arrangement for working two or more needles simultaneously. In making thatch, the straw is placed upon an inclined feed-board, whence it is drawn continuously through the machine, which converts it into a dense woof impervious to rain. The needles are supplied with string, and may be adjusted to produce straight, curved, or zig-zag lines of stitching. As every stitch is perfectly secured, the thatch does not become loose when it is cut into lengths. The machine is adapted for a thatch 5ft. wide, and of any required length, or of any thickness from ¾in. to 2in. It may be worked by ordinary labourers in the winter or during wet weather, and the thatch produced kept rolled up for future use.

Messrs. Headly and Sons, of the Exchange Iron Works, Cambridge, had several novelties. Amongst others, was their hydraulic apparatus for watering streets, lawns, &c., and for extinguishing fires. This useful implement consists of a drum mounted on a pair of wheels, and on which is wound any length of flexible pipe, one end of the pipe being connected to the hydrant. The apparatus is propelled forward, the drum rotates on its axis, the water passes round and through it, and is distributed either by a rigid spreader in front or by a man. A compensating chain gearing is attached for winding up after the water is distributed as far as the pipe extends. We understand that the streets of Reading are now being watered with Messrs. Headly's apparatus. The Cambridge spring chairs at this stand were objects of great interest. The occupier, without leaving his seat, can adjust the chair to any angle at which he may wish to recline.

As a matter of course, Messrs. John Fowler and Co., of Leeds, were strongly represented in steam ploughing and cultivating machinery. They had a very fine 30-horse power traction and ploughing engine, which was kept on the move at the far end of the Show. This engine has been built for Mr. Campbell, of Buscot Park. It has cast steel bearings and weighs 22 tons, and will plough 3ft. 6in. deep. It is fitted with fast and slow speeds, runs well, and stops and reverses rapidly. There were two other engines of 20-horse power each, of this class and make, in the ploughing field. Another great feature at this stand was the Pirie plough, in which the front and back wheels run at an angle in the bottom of the furrow, and are so arranged that they take the whole of the thrust caused by turning over the furrow slice, thus dispensing with the land side and slade, and substituting a rolling for a sliding friction. The left side of the plough is carried by a wheel fixed to a lever. This wheel runs on the unploughed land, and may be arranged as a castor, thus giving great facility in turning the plough at the head-land. This lever also serves the purpose of disengaging the plough from its work at the end of the field, as by lifting it up till a catch on it comes into play, the shares are so raised that they draw themselves out of work and clear the plough from the furrow. The depth of the work is regulated by a T-handle on the lever. On the other end of the rod, connected with this handle, is a screw, by which the man can adjust the depth without stopping the plough. On this plough (unlike all other double furrow ones) the width of furrow may be adjusted from 7in. to 10in. This is done for the first furrow by shifting the front wheel on the bar to which it is attached much as an ordinary wheel plough, and for the back furrow the skief and mouldboard are all shifted on the bevel part of the frame.

We cannot pass the stand of Messrs. Hepburn and Sons, of Long-lane, Southwark, London, without referring to the extensive and varied assortment of leather goods exhibited by them. These consisted of single and double driving bands of every size and length for heavy and light work. This firm have introduced a composite band which is the strongest band made. It will not stretch in work, and the cost of a triple composite is not more than that of an ordinary double leather band. Amongst the other exhibits at this stand were leather hose pipe, fire buckets, laces, hydraulic leathers, &c., &c., all of excellent quality and workmanship—a combination especially desirable in this class of goods.

Mr. Reuben Hunt, of the Atlas Iron Works, Earl's Colne, Essex, had a very good collection of his stock-feeding implements, all of which have obtained a good name, and some of them prizes and medals. Besides these, Mr. Hunt exhibited an improved 1-horse gear about as strong and as compact as any we have seen. It has a driving wheel 3ft. diameter, a cast-iron frame, brass bearings, and is well suited for all purposes to which a horse gear can be applied. Mr. Hunt has effected an important improvement in horse rakes, which consists in almost entirely dispensing with manual labour, any boy old enough to drive a horse being the only attendant required. By simply touching a lever, the rake relieves itself of its load, and, at the same time, the teeth instantly fall to the ground. Its simplicity and certainty of action cannot fail to commend it.

Mr. Walter A. Wood, of 77, Upper Thames-street, London, was strong in mowing and reaping machines, for which he has become celebrated. His new jointed-bar mower attracted attention from the completeness of its details. Some special improvements have been made in these machines during the present year. The shifting lever, for throwing in and out of gear, has been changed from a line, which throws out and in gear by a horizontal side-wise movement, to one which turns in a vertical plane, acting upon a cam-shaped piece, which throws the clutch horizontally out and into gear. The axle on which the machine tilts is not bored to keep the draft iron in place, but is fastened by a separate piece of casting, which clamps the axle by a set screw, thus giving it more strength, as boring the holes tended to weaken the axle. The side pieces of the frame are made wider, which gives more strength to the frame and a wider support to the axle. The steel spring extension piece is fastened to the machine at the lower outer corner of the frame by three bolts, and extends across the joint formed by the front end and outside piece of the main frame, and one of these bolts takes through the end piece. As hitherto made, the extension piece was only fastened to the side piece of the frame, which arrangement afforded no support to the frame from twisting apart at the joint. It may be interesting to note that Mr. Wood commenced the manufacture of mowing and reaping machines in the village of Hoosick Falls, New York, fifteen years since. At that time the manufacture of harvesting machines was confined to a few establishments, and to a class of heavy, cumbersome machines which, although in themselves improvements over the old method of securing crops by hand, were difficult to manage, and trying to the patience of man and beast. Mr. Wood has developed these machines into their present perfect condition, and has stamped them as a class or type with which his name has become identified. The uniform success which has attended the efforts of Mr. Wood is due no less to the careful construction of the machines sent out than to the approved principle upon which they are made. None but the best material of its kind is used, and each machine is put together and tried before shipment. We are informed that the works at Hoosick Falls have facilities for turning out one complete machine every five minutes.

The Beverley Iron and Waggon Company, of Beverley, Yorkshire, had as fine a selection of carts and implements as they ever exhibited. The carts especially were objects of notice and admiration, many detail improvements having been introduced into them by Mr. Norfolk, the Company's managing director. Amongst the new implements was an open cart with a low body for moving stock, &c. The stock can be put in at one end and can walk out at the other on the cart arriving at its destination, thus obviating the difficulty of backing stock out. The cart has a cranked axle, machine-made wheels and springs, and the shafts are easily attached to or removed

from either end. The Beverley Company's wrought-iron wheel —Norfolk's patent—is a valuable invention for hot climates. In these wheels the naves are of cast iron, chilled so hard inside the box or bush part as to resist the file, and fitted with patent wrought-iron oil boxes, bevelled spokes, and convex tires. The axles are forged at the Beverley Iron Works from the best scrap iron, turned and case-hardened. Mr. Norfolk has also introduced some improvements in reaping machines which will be found fully described and illustrated on another page

Messrs. Kinsey, Norton, Hill, and Co., of the Robin Hood Works, Nottingham, had their usual show of engines, in the forefront of which was Mr. Kinsey's horizontal tank and foundation engine, which has met with approval wherever it has been used. These engines are very strong, and entirely self-contained ; the base or bedplate serves as a foundation, and also as a tank and water heater. This firm also exhibited a patent universal suspension steam plough, invented by Mr. Thomas Beards, of Stowe Park, Bucks, and manufactured by the exhibitors. The arrangements are worthy of the attention of agriculturists ; they prevent the sudden strain which causes so many breakages of the haulage-rope on starting. Messrs. Kinsey and Co. are perfecting a new wrought-iron corrugated boiler, which they purpose bringing out ; when the design has been completed, we intend giving particulars.

Messrs. B. and S. Massey, of Openshaw Canal Iron Works, Manchester, exhibited four of their well-known patent steam hammers of small sizes, suitable for the use of agricultural and other machinists. They are very carefully designed and constructed, and are fitted with an exceedingly simple and convenient valve motion, which allows them to be worked either by hand or self-acting at any speed up to about 600 blows per minute.

Although our notice has extended to a considerable length—in fact, as far as we can allow it to extend this week—we find we have not yet used all our notes, several exhibitors still remaining for notice. We shall, therefore, conclude our remarks next week.

We append a list of the prizes awarded at the Manchester Show, which is compiled from the official statement. This statement, we may add, was printed at the Show by Messrs. Gadsby and Arnold, of Crane-court, Fleet-street, London. This firm had a stand at the Show—a regular printing establishment—from whence was issued during the Show a daily paper, and at which the Royal Agricultural Society's printing for the time being was done. Messrs. Gadsby and Arnold were also exhibitors of a double-demy Wharfdale cylinder printing machine, at which their printing was done. They also showed a very good paper-cutting machine and a card machine for printing without ink, the invention of M. Leboyer, of Riom. This temporary printing establishment proved of great use, not only to the Agricultural Society, but to the exhibitors at large, who were not slow to avail themselves of the convenience. A considerable staff found employment both day and night, and turned out their work in a very satisfactory manner.

JUDGES.

F. J. Bramwell, C.E., 37, Great George-street, London, S.W. (engineer judge).

Mowing and Haymaking Machines and Horse Rakes.—John Hemsley, Shelton, Newark, Notts; J. W. Kimber, Tubney Warren, Abingdon; Matthew Savidge, Sarsden Lodge Farm, Chipping Norton.

Reaping, Sheaf-Binding, and Corn-Drying Machines.—John Hicken, Dunchurch, Rugby; W. Sanday, Radcliffe-on-Trent, Nottingham; W. Sadler, Ferrygate, Drem, N.B.

Manure Distributors, Potato Getters, Waggons, and Carts.—John Wheatley, Neswick, Driffield; Henry Cantrell, Baylis Court, Slough, Bucks; John Gibson, Woolmet, by Dalkeith, N.B.

Miscellaneous and Dairy Utensils.—H. B. Caldwell, Monkton Farleigh, Bradford-on-Avon; F. Sherborn, Bedfont, Middlesex; J. K. Fowler, Willowbank, Aylesbury.

Plans and Models.—J. Coleman, Escrick Park Office, York; J. Bailey Denton, 22, Whitehall-place, London; J. E. Watson, Newcastle-on-Tyne.

PRIZES.

SECTION I.

New patent Paragon mower, Richard Hornsby and Sons, 636, £20.

Grass mowing machine, Walter A. Wood, 478, £17.

Two horse grass mower, Burgess and Key, 174, £13.

The judges are of opinion that all the machines exhibited under the title of "one-horse mowers" are far too heavy in draft to be worked by one horse, and, therefore (under clause 3 of their instructions), withhold the sum assigned for prizes in this class.

SECTION II.

Haymaker, W. N. Nicholson, 5636, £16.

Haymaker, J. and F. Howard, 3711, £14.

SECTION III.

The prize for hay collectors is withheld for want of merit.

SECTION IV. CLASS I.

Reaping machine with self-delivery in sheaf, clear of the horse track, Richard Hornsby and Son, 644, £25.

Reaping machine with self-delivery in sheaf, clear of the horse track, Richard Hornsby and Son, 642, £20.

Reaping machine with self-delivery in sheaf, clear of the horse track, Samuelson and Co., 3938, £15.

SECTION IV. CLASS II.

Reaping machine, with self-delivery in swathe, clear of the horse track, A. C. Bamlett, 3975, £25.

Reaping machine, with self-delivery in swathe, clear of the horse track, Burgess and Key, 178, £20.

Reaping machine, with self-delivery in swathe, clear of the horse track, Hornsby, 646, £15.

Reaping machine with self delivery, Richard Hornsby and Son, 648, £12.

Reaping machine with self delivery, A. C. Bamlett, 3981, £10.

Reaping machine with self delivery, Samuelson and Co., 3989, £8.

SECTION IV. CLASS IV.

Combined self-raking, reaping, and mowing machine, Samuelson and Co., 3940, £20.

New patent paragon combined mower and reaper, Richard Hornsby and Sons, 649, £10.

SECTION IV. CLASS V.

Reaping machine with one horse, A. C. Bamlett, 3980, £12.

Reaping machine with one horse, Richard Hornsby and Son, 653, £10.

Reaping machine with one horse, R. Cuthbert and Co., 45, £3.

SECTION V.

Horse rake, Ransomes, Sims, and Head, 766, £20.

Horse rake, J. and F. Howard, 3714, £10.

SECTION VI. CLASS I.

Pair horse waggon, William Crosskill and Son, 1403, £15.

Pair horse waggon, Henry Hayes and Son, 733, £10.

Pair horse waggon, Thomas Milford and Sons, 356, £5.

SECTION VI. CLASS II.

Other waggons, Henry Hayes and Son, 732, £10.

Other waggons, Beverley Iron and Waggon Company, 1716, £5.

Other waggons, Beverley Iron and Waggon Company, 1804, £5.

SECTION VII. CLASS I.

Single horse cart, Henry Hayes and Son, 739, £8.

Single horse cart, Thomas Corbett, 3839, £7

Single horse cart, William Crosskill and Son, 1405, £5.

SECTION VII. CLASS II.

Two horse carts, Henry Hayes and Son, 741, £8.

Two horse carts, William Ball and Son, 1005, £7.

Two horse carts, Beverley Iron and Waggon Company, 1724, £5.

SECTION VII. CLASS III.

Harvest cart, Henry Hayes and Son, 744, £10.

Harvest cart, Frank Milford, 27, £5.

SECTION VII. CLASS IV.

Market cart on springs, Beverley Iron and Waggon Company, 1730, £6.

Market cart on springs, Thomas Corbett, 3841, £4.

SECTION VII. CLASS V.

Liquid manure cart, Isaac James, 392, £6.

Liquid manure cart, Thomas Baker, 351, £4.

SECTION VIII.

Carriage for removing stock, implements, &c., Thomas Corbett, 3842, £15.

Carriage for removing stock, implements, &c., Beverley Iron and Waggon Company, 1740, £5.

HIGHLY COMMENDED.

SECTION I.

Patent grass mowing machine, Samuelson and Co., 3934.

SECTION IV. CLASS I.

Reaping machine, with self delivery in sheaf, clear of the horse track, Richard Hornsby and Son, 643.

Reaping machine, with self delivery in sheaf, clear of the horse track, Richard Hornsby and Son, 645.

SECTION IV. CLASS V.

One horse reaper, Samuelson and Co., 3948

SECTION V. CLASS V.

Liquid manure cart, Robert and John Reeves, 528.

Liquid manure cart, Coleman and Morton, 569.

SECTION VI. CLASS I.

Pair horse waggon, Beverley Iron and Waggon Company, 1714.

SECTION VI. CLASS II.

Other waggon, George Ball, 4089.

Other waggon, Humphrey Bracewell, 4058.

SECTION VII. CLASS I.

Single horse cart, William Chapman, 81.

Single horse cart, Beverley Iron and Waggon Company, 1718.

SECTION VII. CLASS II.

Two horse cart, Thomas Corbett, 3840.

Two horse cart, F. P. Milford, 26.

COMMENDED.

SECTION I.

Two horse mower, A. C. Bamlett, 3968

SECTION IV. CLASS II.

Reaping machine, with self delivery in swathe, clear of the horse track, Beverley Iron Company, 1707.

Reaping machine, with self delivery in swathe, clear of the horse track, Beverley Iron Company, 1709.

SECTION VI. CLASS I.

Pair horse waggon, William Chapman, 28

Pair horse waggon, William Ball and Son, 1002

SECTION VI. CLASS II.

Other waggon, Thomas Corbett, 3838.

Other waggon, Henry Hayes and Son, 737

SECTION VII. CLASS I.

Single horse cart, Thomas Milford and Sons, 359

Single horse cart, William Ball and Son, 1004

SECTION VII. CLASS II.

Two horse cart, Woods Cocksedge and Warner 141.

Two horse cart, Samuel Harrison, 171

SECTION VII. CLASS III.

Harvest cart, Beverley Iron and Waggon Company, 1729.

SECTION VIII.

Carriage for removing stock, implements, &c., Beverley Iron and Waggon Company, 1739.

GOLD MEDAL.

Smut and separating machine, called "Eureka," Nell, Harrison, and Co., 6514.

SILVER MEDALS.

One horse gear, Richmond and Chandler, 885.

Machine for net folding of sheep, R. Winder, 2186.

Patent two-row turnip and mangold sower, T. M'Kenzie and Sons, 2400.

Improved steam road roller, Aveling and Porter, 4301

Weighing machine, Pooley and Son, 6166

Machine for boring in the earth, Mather and Platt, 7608.

Machine for drying corn by steam heater cylinders, Davey, Paxman, and Davey, 6185.

THE ROYAL INSTITUTION.

OWING to the pressure caused by the proceedings of the Agricultural Society, and other business our notice of the closing proceedings of the Royal Institution session has been considerably delayed. Since the last summary, the principal features of interest at the Royal Institution were a lecture by Dr. William Odling, F.R.S., on "The Simplest Organic Compounds," and another by Dr. John Tyndall, M.R.I., on "The Constitution of the Interstellar Ether." At Dr. Odling's lecture, the Prince of Wales presided, and the speaker explained the difficulties which prevent chemists from knowing much of the actual grouping of the atoms in compound chemical substances. Professor Tyndall, in his lecture, spoke of the difficulty of ascribing the phenomena of light to anything but the wave motion of a fluid of definite mechanical properties. We only know of things, he said, by their effects, and the first question relating to light is "What can it do?" It can do mechanical work, and be made to raise weights, and to turn wheels. The human mind cannot conceive of motion being thus produced without motion in the thing causing the movement. Light takes eight minutes to travel from the sun to the earth, and separating in idea a cubic mile of the space between the sun and the earth from the surrounding space, it will be found most difficult to form any other theory than that

of wave motion to explain the phenomena taking place within the said cubic mile. By the wave theory, Sir William Hamilton came to the conclusion that conical refraction ought to take place in certain crystals, such is arragonite. After theory pointed to this conclusion, the crystals were examined, and found to present the expected phenomena, which had never before been seen by human eyes. The wave theory, therefore, is as much strengthened by the foregoing facts, as was the theory of gravitation by the discovery of the planet Neptune, in consequence of the mathematical calculations of Leverrier.

ELECTRICITY AND TELEGRAPHY.

WE regret to have to announce that a fault was discovered on Saturday last in the 1866 Atlantic cable, the distance being estimated at about 130 miles from the Irish coast. The fault is not of so serious a nature but that communication can be carried on; it has been, however, determined to take steps to immediately repair it. This is the fourth interruption in this cable, which may be looked upon as excessively unfortunate; the 1865 cable, however, is, and always has been, in perfect condition.

The manufacture of the British Indian Submarine cable, at the Telegraph Construction and Maintenance Company's works at East Greenwich, is making rapid progress, over 500 miles of the deep-sea section between Aden and Bombay being completed. The "Great Eastern" having arrived at Sheerness from the successful laying of the French Atlantic cable, will be at once put in order to receive the British Indian cable, the major portion of which she will carry out in the winter.

The main Black Sea cable, of about 200 miles in length, has been successfully submerged by Mr. Siemens.

The Norwegian cable from Peterhead to Norway has also just been laid by Mr. Henley.

Mr. Henley is now manufacturing at his works a length of cable for the Mediterranean Extension Telegraph Company, to form a duplicate line between Malta and Sicily.

The various arbitrations between the Post Office and the telegraph companies having been brought to a satisfactory conclusion, the Money Bill has been brought in, and is now passing through its various phases. It will before the close of the session have completed its parliamentary stages, and shortly we hope to place the subject before our readers. The total amount required for the purchase of the various telegraphs is estimated at £7,000,000.

NOTES ON RECENT SCIENTIFIC DISCOVERIES, AND THEIR PRACTICAL APPLICATIONS.

NITRO-GLYCERINE—CHLORIDE OF NITROGEN—SIEMENS' FURNACE IN THE MANUFACTURE OF IRON.

NITRO-GLYCERINE is not a very recent discovery, nor are the dangers of it exactly a novelty. We only allude to it here to point out that if its use in the liquid form must be continued, it can be easily prepared on the spot where it is required, and at the time it is wanted. Such a plan is followed, on the suggestion of M. Kopp, in some French quarries, and might easily be adopted in Wales. Nitro-glycerine is made by submitting glycerine to the action of a mixture of two parts of sulphuric acid and one part of nitric acid, the use of the sulphuric acid being to concentrate the nitric acid which is alone concerned in the re-action. In the apparatus ordinarily used, the glycerine and the acids are allowed to mix in thin streams, and are afterwards agitated together for a short time in the receptacle into which they flow. The nitro-glycerine is then allowed to settle at the bottom, the acids are drawn off, and after a single washing with water the explosive is ready for use. There is nothing in this process which could not be managed by any intelligent labourer, and we do not see why it should not be generally adopted, in place of incurring the risks unavoidable in transporting and storing the article.

While writing of explosives, we may mention the curious circumstance recently discovered by Mr. Abel, that the explosion of perfectly dry chloride of nitrogen in an open vessel produces comparatively slight destructive effects. A drop exploded on a watch glass, for example, only breaks the glass into two or three fragments, while the same quantity of chloride of nitrogen, if wet, shatters the glass to atoms. The thin layer of water, in fact, acts like the water tamping used with nitro-glycerine in a drill hole. Chloride of nitrogen has only been the subject of some researches by MM. Deville and Hautefeuille. As is well known, it is exploded by friction, by percussion, by contact with grease, and by heat, and, in our experience, sometimes goes off without any obvious cause at all. Owing to the extreme danger attending experiments with it, the exact degree of heat at which it explodes has never been ascertained, but the chemists named above have determined that it can be made to boil without exploding. As regards the force exerted by the explosion of chloride of nitrogen, the same gentlemen have ascertained that when exploded in confinement, the pressure of the gas liberated cannot be less than 3500 atmospheres. This is an interesting scientific fact; but chloride of nitrogen appears to be so capricious and unstable a body that no profitable use is likely to be made of the tremendous energy it is able to develope.

We may mention that some experiments on the application of Siemens' furnace to the manufacture of iron in France appear to have yielded extraordinarily successful results. We may give an account of the mode in which the furnace is applied, when fuller details come to hand. At present, we need only say that with the apparently small scale on which it has been tried, a ton of cast iron is produced with the expenditure of an equal weight of coal. This result, if established, would, no doubt lead to a very general adoption of the furnaces.

THE PALLISER GUN.

SOME particulars are to hand relating to the practical working of a number of guns converted upon Major Palliser's system, and which will prove interesting to our readers. In 1866 eight cast-iron 24-pounder and 32-pounder smoothbore guns were converted by Major Palliser into 56-pounder and 64-pounder rifled guns, with a view of ascertaining whether our large stock of cast-iron guns could be advantageously converted into rifled cannon. Of these eight experimental guns one was tested for endurance, by firing continuously, with shot of 64lb. weight, until it had completed 2,285 rounds, of which 2,170 were with 8lb. charge, eighty-eight with 14lb., two with 12lb., one with 10lb., and twenty-four with 16lb. and 86lb. shot. The power of endurance of the converted guns was thus thoroughly proven. Six of the remaining guns were issued for service to home and foreign stations, in order that the Royal Artillery might have an opportunity of practising with them. The preliminary reports from these stations have now arrived, and are, on the whole, very satisfactory. The 64-pounder issued to Devonport has fired over 300 rounds, the gun is reported to be perfectly serviceable, and no complaints have been made of any difficulty in working. The Sheerness 56-pounder gun has fired 200 rounds, and the practice is reported as excessively accurate. The report from Gibraltar speaks in high terms of the accuracy of the 56-pounder issued to that station. The gun has fired 400 rounds, and is perfectly serviceable. The 56-pounder issued to Malta has fired 250 rounds. At Dover a 64-pounder has fired over 180 rounds with remarkable accuracy. The gun is spoken of as being, for handiness and fitness for rough work and exposure, in every way equal to the old 32-pounder. The 64-pounder on board the "Excellent" has fired over 480 rounds with great accuracy, the working of the gun carriage, &c., being in every way satisfactory. These reports are of much interest, proving, as they do, that the converted 64-pounder gun is fully equal to the more expensive wrought-iron gun of the same calibre.

THE plans of Mr. Kneass have been adopted for an iron bridge over the Schuylkill, at South-street, Philadelphia. The centre and river piles will be of iron, sunk by the pneumatic process; the length of the bridge will be 2,488ft., and the clear height 32ft. above high water.

ROGERS' PROJECTILE ANCHOR BLOCK AND LIFE-SAVING APPARATUS.

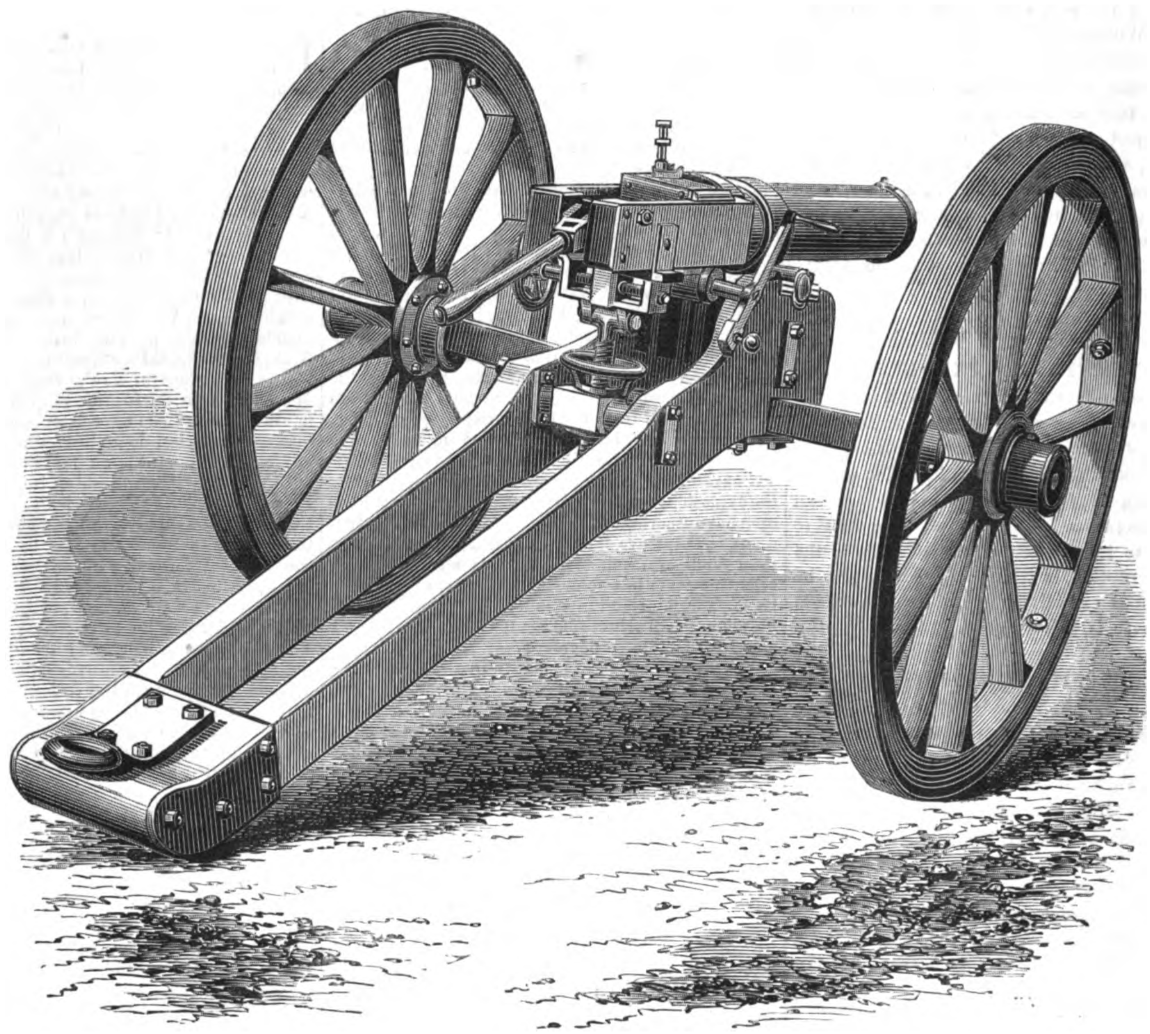
IT is with pleasure we observe that this useful and humane invention is now in a fair way of becoming an established fact, and acknowledged as a requirement. We have commented upon this invention several times, and are satisfied that it deserves the fullest attention of the public as a means of life-saving on seaboard. Mr. Rogers was requested by the Lords Commissioners of the Admiralty to demonstrate his principle before the authorities at her Majesty's dockyard, Sheerness, on Tuesday and Wednesday, the 20th and 21st inst. The trials took place on the above dates with model anchor blocks, cones, &c., to the entire satisfaction of Vice-Admiral R. L. Warren, Commander-in-Chief at the Nore; Captain the Hon. A. A. Cochrane, C.B., superintendent of Sheerness Dockyard; Captain Paul, staff superintendent; Mr. A. B. Sturdee, master shipwright, and other nautical men. The experiments embraced a very interesting series, including, amongst others, the use of the apparatus in making communication with the shore from a ship, by the aid of Mr. Rogers' non-choking block; also from the shore to the sea for the purpose of launching boats through the surf by shore aid and not by the exertion of the crew. Its use as a life-saving means was fully demonstrated in the supposed case of a vessel being wrecked under a cliff, bluff, or headland, where it would be impossible to get boat communication. The anchor, with block and double line, was fired the height of a cliff, proving that it would be a means of escape from the wreck to the top, when no other method could be used. We trust we shall shortly be able to announce that this humane and efficient means of giving aid to seamen and ships in distress will be placed upon our coasts and on board our vessels to be used in case of need.

NEW IRONCLADS.

ANNEXED is a statement showing the armour-clad ships now in course of construction for the Admiralty, and the establishments at which they are being built:—The "Sultan," 12, 5,226 tons, 1,200-horse power, and the "Glatton," 2, 2,709 tons, 500-horse power, double screw turretship, building at Chatham dockyard; the "Iron Duke," 14, 3,774 tons, 800-horse power, double screw, building at Pembroke dockyard; the "Swiftsure," 14, 3,893 tons, 800-horse power, and the "Triumph," 14, 3,893 tons, 800-horse power, building by the Palmer Shipbuilding Company at Jarrow-upon-Tyne; the "Hotspur," 2, 2,637 tons, 600-horse power armour-plated ram, building at the yard of Messrs. Napier and Sons, Glasgow; and the "Vanguard, 14, 3,774 tons, 800-horse power, building by Messrs. Laird Brothers, Birkenhead. In addition to the above, the "Abyssinia," 4, 1,854 tons, 200-horse power, and the "Magdala," 4, 2,107 tons, 250-horse power, double-screw iron armour-plated turretships, are building for the defence of Bombay, the former by Messrs. Dudgeon, at Poplar, and the latter by the Thames Iron Shipbuilding Company at Blackwall. They are said to be in such a forward state that they will be completed during the present or early in the ensuing year. As soon as one of the building slips becomes vacant at Chatham dockyard, a new armour-plated ram, to be named the "Rupert," of 3,159 tons, and 700-horse power, is to be commenced at that establishment. A new armour-plated turretship, the "Devastation," of 4,406 tons and 800-horse power, from the designs of Mr. E. J. Reed, C.B., has been recently commenced at Portsmouth dockyard.

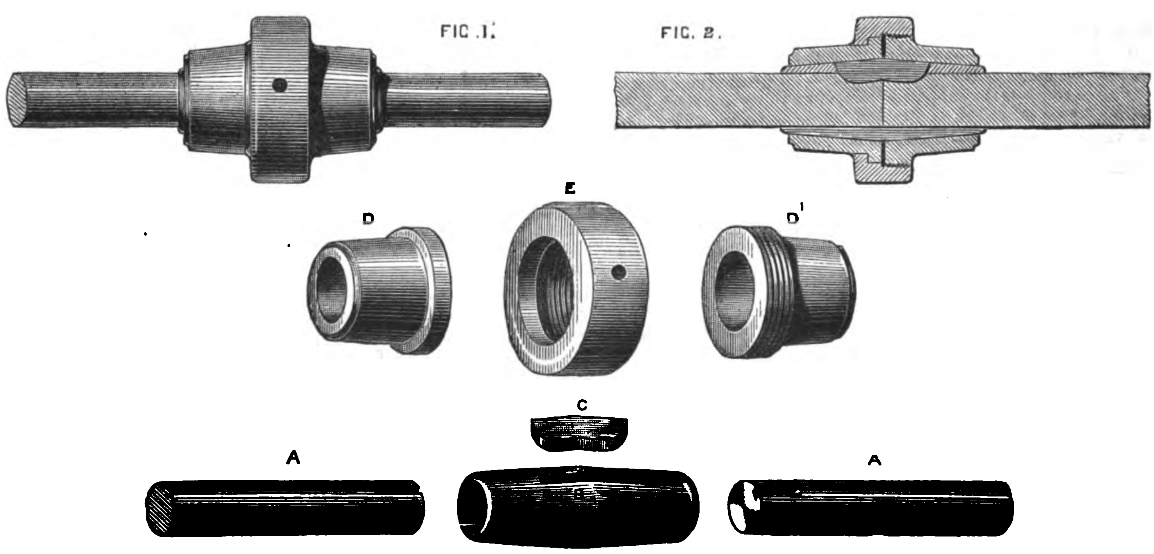
AN interesting discovery has been made near Corbridge within the last few days, by which the true site of the Roman bridge which crossed the Tyne there has been ascertained. Remains of the land pier were found on a rock, which only stands about 4ft. from the bank, beyond which the river bottom consists of mud and shingle. At a distance of 50ft. from the face of the land pier the foundations of the first pier were found by removing about 1ft. of mud. They are constructed in the very strongest possible manner, a strong oak framework enclosing stones 5ft. long by 12in. broad, the oak again inserted across at every five stones, secured to a centre piece, which traverses the whole. At the east end piles are driven in to secure the platform from moving. The most interesting remain is one of the oak beams of the bridge lying on this foundation, burried in mud and rubbish, clearly in the postiion as it fell when the bridge was destroyed a large place a few feet from the end being burnt nearly half through the beam, which, though much decayed, is yet quite in a sufficiently good state of preservation.

THE BELGIAN MITRAILLENSE.



SELF-CENTREING COMPRESSION COUPLING.

BY A. RANSOME AND CO.



THE BELGIAN MITRAILLEUSE.

WE have of late occasionally recorded the remarkable results of firing of a new multiple barrelled field gun in Belgium. It will doubtless interest our readers to know more of this deadly weapon. We therefore give a perspective view of the gun, which is taken from an official photograph. Although the latest weapon of its kind, it is in principle no novelty, having had several prototypes, the well known Gatling gun being one of them. The present gun is the invention of M. de Montigny, of Belgium, and is stated to be the machine gun with which the French military authorities experimented last year. It consists of thirty-seven steel rifled barrels, of about the usual small-bore calibre. These being hexagonal prisms externally, are packed together to constitute a sort of cylinder, which, being fixed within a bored and turned wrought-iron tubular casing, are all soldered to each other and into the tube. The rear end of the tube consists of a stirrup or U-shaped frame, within the vertical jaws or sides of which are the planed chases within which the breech blocks, holding the ammunition to be fired, are in succession placed. The tube (*i.e.*, the whole gun), is mounted on trunnions upon the hard wood cheeks of a light field gun carriage of double trail, and is provided with the usual arrangement of elevating screw, and with a horizontal screw for fine adjustment in azimuth. The sights at breech are movable, and elevate for range, &c., the line of aim being about 36in. in length. The breech block is a solid parallelopiped, bored out with thirty-seven chambers. Behind each of these is a lock—that is to say, a spiral spring and detent, which on the release of the latter drives forward a needle into the centre of the cartridge in the chamber before it, and so communicates a central ignition. One handle which projects in the rear in line with the piece, clamps forward firmly the compound breech

piece when dropped into place, or at once releases it, when it has to be replaced after its exhaustion by fire. At one side of the proper sight of the gun is seen a handle, by means of which each lock of each barrel is in succession released, and that barrel fired. The rate of firing is thus dependent simply upon that at which this handle or winch is manipulated.

It is stated that at least 350 shots per minute can be discharged from one piece, and by one man, but that stands in need of confirmation. The rapidity of fire is, no doubt, great, for Major G. V. Fosbery, V.C., B.S. Corps, who has been investigating this arm abroad, saw ten blocks exhausted in about three minutes, when aiming at a target screen, at the heath of Brascäat, the Belgian Artillery practice range. These experiments appear to have been made at ranges of 430 yards, and at extreme ones of 1,100 yards, the screen being nearly 100ft. long by 9ft. high, with a central portion of about one-fourth the whole length of 12ft. in height. At the short range nearly 85 per cent. of the projectiles struck, and had there been no missfires (there were no less than forty out of the 370) this percentage would, no doubt, have been higher. At the longest range the fire was much more wild, and from the constant divergence of the cone of dispersion, as well as from all other sources of inaccuracy or of divergence, the number struck was so much smaller in proportion that no exact trials seem to have been made. The cartridges are made up with their projectiles and priming, and are readily dropped simultaneously by mechanical means into their chambers, and by the aid of a perforated steel plate which is the cartridge holder, and grips the necks of the cartridge cases, these are easily and simultaneously extracted, so as to admit of the block being recharged. By a change in the nature of the breech blocks or steel plates, or both, this gun may be instantly converted into a strict volley gun, and all the thirty-seven barrels be discharged at once. The main military uses for these pieces will be special.

SELF-CENTREING COMPRESSION COUPLING.

In our notice last week of the Agricultural Show at Manchester, we referred to a very good coupling, which we found at the stand of Messrs. Allen Ransome and Co., of King's-road, Chelsea. The accompanying engraving represents this coupling, which possesses very striking advantages over those hitherto used. Fig. 1 shows the coupling in elevation when fixed upon a line of shafting, and fig. 2 is a longitudinal section of the same, while the various parts are shown below in detail. A A represent the ends of two lengths of shafting which are to be coupled together. B is a cast-iron split sleeve, bored parallel inside to suit the size of the shafting, and having its outer surface turned to the form of a double cone. C is a steel key fitted into corresponding slots in ends of the shafts A A and sleeve B. D D¹ are two outer compression shells, bored conical to fit the double cone of the sleeve B. E is a turned cast-iron collar or ring nut, having a strong thread formed upon its inner circumference on one side, to fit upon a corresponding screw cut on the collar of the compression shell D¹. By screwing up the ring nut E, the conical shells D D¹ are drawn together and compress the split sleeve B, so that it tightly grips the ends of the shafts, and holds them firmly together. The couplings can be supplied of any size, independently of the shafting, and do not require to be turned in their places on the shafting. The split sleeve, when drawn together by the action of the conical compression shells, closes on the centre, and thus necessarily brings the lengths of shafting into a perfectly straight line. A single length in a line of shafting united with the couplings can be readily taken out to shift a pulley without disturbing the other lengths. No bolts, nuts, or tight keys being used, these couplings are readily fixed, one minute being ample time to uncouple or couple up each joint. Although lighter than those in ordinary use, the couplings are much stronger, as from their peculiar construction, the strain is equally diffused throughout every part of them. Being free from any projections, the couplings are not only symmetrical in appearance, but they can be used as driving pulleys for slow speeds, without fear of injuring the belts.

The Keystone Bridge Company, of Pittsburg, has contracted to build a wrought-iron bridge on the Boston, Hartford, and Erie road at Middletown, Connecticut; the bridge will be 1,200ft. long.

PATENT LAW FOR THE DOMINION OF CANADA.

A NEW Patent Law Act for Canada was assented to by the Governor General on the 22nd of June last. We append a copy of a portion of this act, and purpose giving the remainder next week. We shall then enter upon a discussion of its merits, or rather demerits, for it is especially unsatisfactory, and involves matters of great importance to non-resident alien inventors, whom it excludes from the benefits of its provisions.

Her Majesty by and with the advice and consent of the Senate and House of Commons of Canada, enacts as follows:—

PATENT OFFICE CONSTITUTED.

1. There shall be attached to the Department of Agriculture, as a branch thereof, an office to be named the Patent Office; and the Minister of Agriculture for the time being shall be the Commissioner of Patents of Invention; and it shall be the duty of said Commissioner to receive all applications, fees, papers, documents and models for patents, and to perform such acts and things respecting the granting and issuing of patents for new and useful inventions, discoveries, and improvements as are herein provided for; and he shall have the charge and custody of the books, records, papers, models, machines, and other things belonging to the said office.

2. The Commissioner shall cause a seal to be made for the purposes of this Act, and may cause to be sealed therewith letters patent and other instruments and copies proceeding from the Patent Office; and all courts, judges, and other persons whomsoever shall take notice of such seal, and receive impressions thereof in evidence, in like manner as impressions of the Great Seal are received in evidence, and shall also take notice of and receive in evidence, without further proof and without production of the originals, all copies or extracts certified under the seal of the said office to be copies or extracts from documents deposited in such office.

3. The Commissioner may, from time to time, subject to the approval of the Governor in Council, make such rules and regulations, and prescribe such forms, as may appear to him necesssary and expedient for the purposes of this Act; and notice thereof shall be given in the "Canada Gazette"; and all documents, executed after the same and accepted by the Commissioner, shall be held valid so far as relating to proceedings in the Patent Office.

4. The Deputy of the Minister of Agriculture shall be the Deputy Commissioner of Patents of Invention; and the Government may, from time to time, appoint such clerks and officers under him as may be necessary for the purpose of this Act, and such clerks and officers shall hold office during pleasure.

5. The Commissioner shall cause a report to be prepared annually and laid before Parliament of the proceedings under this Act, and shall, from time to time, and at least once a year, publish in the "Canada Gazette" a list of patents granted, and may, with the approval of the Governor in Council, cause such specifications and drawings as may be deemed of interest, or essential parts thereof, to be printed from time to time for distribution or sale.

WHO MAY OBTAIN PATENTS.

6. Any person having been a resident of Canada for at least one year next before his application, and having invented or discovered any new and useful improvement on any art, machine, manufacture or composition of matter, not known or used by others before his invention or discovery thereof, or not being at the time of his application for a patent in public use or on sale in any of the provinces of the dominion, with the consent or allowance of inventor or discoverer thereof, may, on a petition to that effect presented to the Commissioner, and on compliance with the other requirements of this Act, obtain a patent granting to such person an exclusive property therein; and the said patent shall be under the seal of the Patent Office and the signature of the Commissioner, or the signature of another member of the Privy Council, and shall be good and avail to the guarantee, his heirs, assigns, or other legal representatives, for the period mentioned in such patent, but no patent shall issue for an invention or discovery having an illicit object in view, nor for any mere scientific principle or abstract theorem.

7. An original and true inventor or discoverer shall not be deprived of the right to a patent for his invention or discovery by reason of his having, previously to his application, taken out a patent therefor in any other country, at any time within six months next preceding the filing of his specification and drawing as required by this Act.

8. The patent may be granted to any person to whom the inventor or discoverer, entitled under the sixth section to obtain a patent, has assigned or bequeathed the right of obtaining the same, and the exclusive property in the invention or discovery in Canada, or in default of such assignment or bequest, to the executor or administrator of the deceased inventor or discoverer or other legal representative.

9. Any person having been a resident of Canada for at least one year next before his application, and who has invented or discovered any improvement on any patented invention or discovery, may obtain a patent for such improvement, but shall not thereby obtain the right of vending or using the original invention or discovery, nor shall the patent for the original invention or discovery confer the right of vending or using the patented improvement.

10. In cases of joint applications, patents shall be granted in the names of all the applicants; and in such cases, any assignment from one of the said applicants or patentees to the other shall be registered in the manner of other assignments.

CONDITIONS AND FORMALITIES.

11. Every applicant for a patent, before he can obtain the same, shall make oath, or when entitled by law, to make an affirmation instead of an oath, shall make an affirmation that he verily believes that he is, or that the person whose assignee or representative he is or was the true inventor or discoverer of the invention or discovery for which the patent is solicited, and that he, or the person whose assignee or representative he is, was a resident of Canada for one year next before the application, or in case of death of the inventor or discoverer, for one year next before such death. Such oath or affirmation may be made before any justice of the peace in Canada; but if the applicant is not at the time in Canada, the oath or affirmation may be made before any minister plenipotentiary, *chargé d'affaires*, consul or consular agent holding commission under the Government of the United Kingdom, or any judge of the country in which the applicant happens at the time to be.

12. The petitioner for a patent shall, for all the purposes of this Act, elect his domicile at some known and specified place in Canada, and mention the same in his petition for a patent, and he shall in the same petition state the place or places in Canada at which he, or, if his application be as assignee or representative of the person whose assignee or representative he is, was resident during the year of residence required by this Act, and the period of residence at each such place.

13. The applicant shall, in his petition for a patent, insert the title or name of his invention or discovery, its object, and a short description of the same, and shall distinctly allege all the facts which are necessary under this Act to entitle him to a patent therefor, and shall with the petition send in a written specification, in duplicate, of his invention or discovery, describing the same in such full, clear, and exact terms, as to distinguish it from all contrivances or processes for similar purposes.

14. The specification shall correctly and fully describe the mode or modes of operating contemplated by the applicant, and shall state clearly and distinctly the contrivances and things which he claims as new, and for the use of which he claims an exclusive property and privilege; it shall bear the name of the place where it is made, the date, and be signed by the applicant and two witnesses; in the case of a machine, the specification shall fully explain the principle and the several modes in which it is intended to apply and work out the same; in the case of a machine, or in any other case where the invention or discovery admits of illustration by means of drawings, the applicant shall also, with his application, send in drawings in duplicate, showing clearly all parts of the invention or discovery, and each drawing shall bear the name of the inventor or discoverer, and shall have written references corresponding with the specification, and a certificate of the applicant that it is the drawing referred to in the specification; but the Commissioner may require any greater number of drawings than those above mentioned, or dispense with any of them, as he may see fit; one duplicate of the specification and of the drawings, if any drawings, shall be annexed to the patent, of which it forms an essential part, and the other duplicate shall remain deposited in the Patent Office.

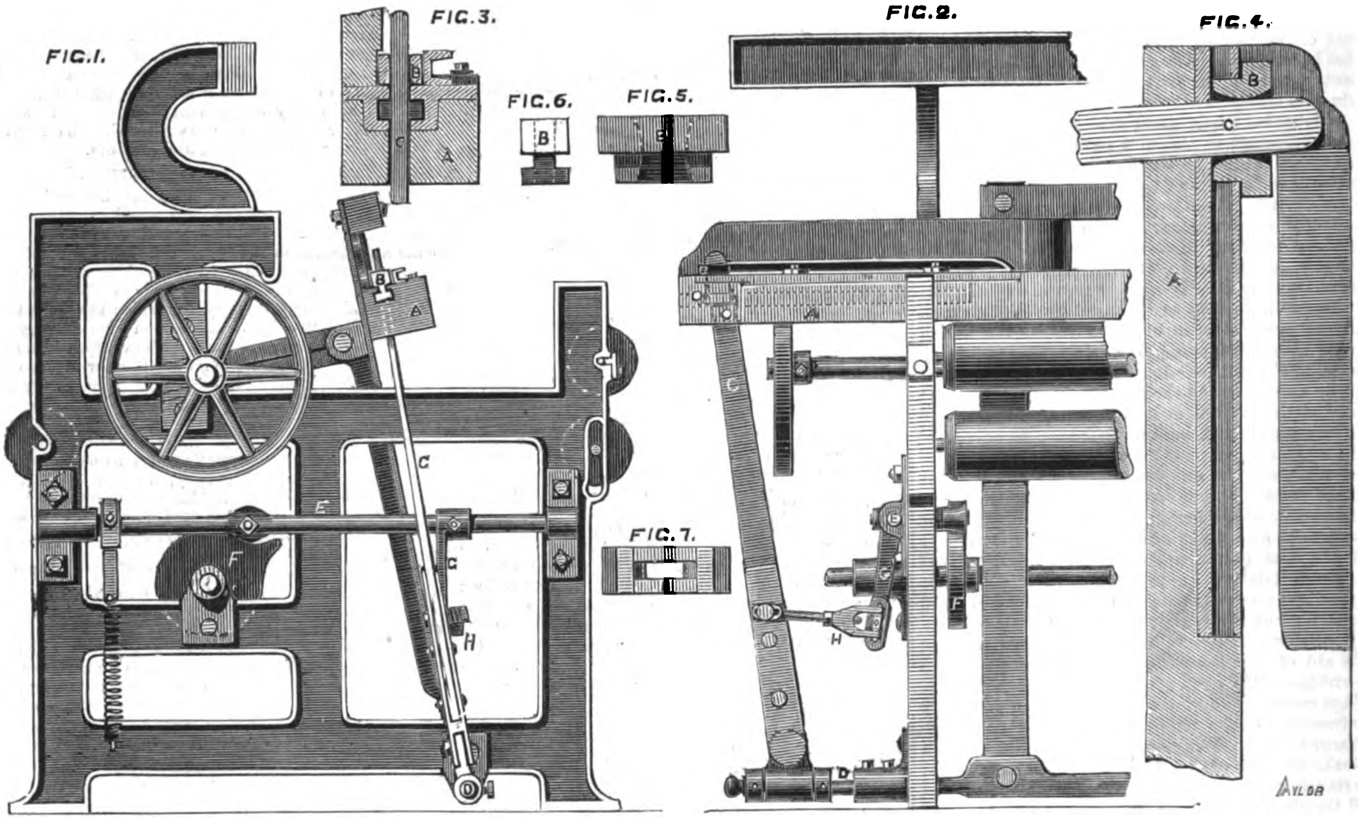
15. The applicant shall also deliver to the Commissioner, unless specially dispensed from so doing for some good reason, a neat working model of his invention or discovery on a convenient scale, exhibiting its several parts in due proportion, whenever the invention or discovery admits of such model; and shall deliver to the Commissioner specimens of the ingredients, and of the composition of matter sufficient in quantity for the purpose of experiment, whenever the invention is a composition of matter; provided such ingredients and composition are not of an explosive character, or otherwise dangerous, in which case they are to be furnished only when specially required by the Commissioner, and then with such precautions as shall be prescribed in the said requisition.

CONTENTS, DURATION, SURRENDER, RE-ISSUE OF PATENTS AND DISCLAIMERS.

16. Every patent granted under this Act shall recite briefly the substance of the petition on which it is granted, and shall contain the title or name of the invention or discovery, and a short description of the same, referring for a fuller detail to the specification; and shall grant to the patentee, his assigns and legal representatives, or in trust, as the case may be, for the period therein mentioned from the granting of the same, the exclusive right, privilege, and liberty of making, constructing, and using, and vending to others to be used, the said invention or

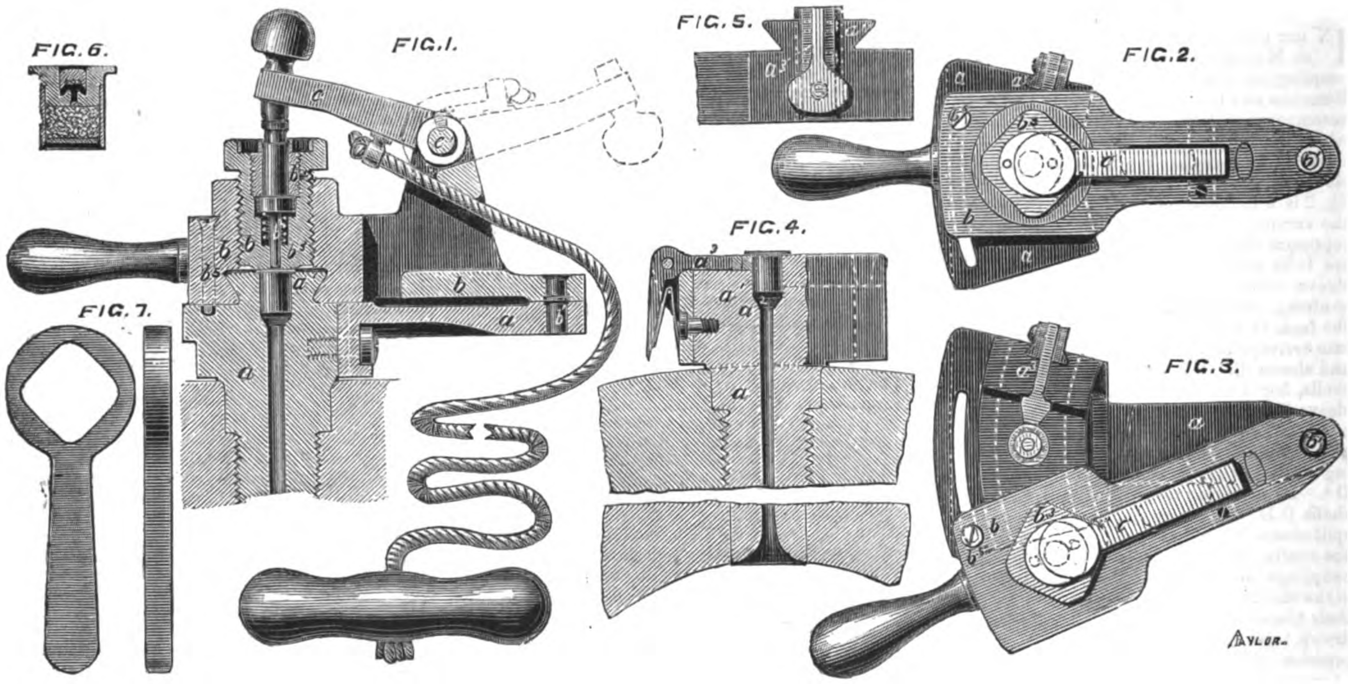
IMPROVEMENTS IN LOOMS.

BY MR. PRIESTLY AND MR. DEIGHTON.



APPARATUS FOR DISCHARGING ORDNANCE.

BY MR. J. VAVASSEUR.



discovery; and shall contain a condition that it is nevertheless subject to adjudication before any court of competent jurisdiction.

17. Patents of invention or discovery issued by the Patent Office shall be valid for a period of five years; but at or before the expiration of the said five years the holder thereof may obtain an extension of the patent for another period of five years, and after those second five years may again obtain a further extension for another period of five years; and the instrument delivered by the Patent Office for such extension of time shall be in the form which may be from time to time adopted, and shall be made in duplicate, one duplicate to remain of record and be duly registered, and the other to be attached, with a reference, to the patent, under the seal of the Patent Office, and signature of the Commissioner, or any other Privy Counsellor in case of absence of the Commissioner.

18. Every such patent and every instrument for granting a further extension of any patent shall, before it is signed by the Commissioner, or any other member of the Privy Council, and before the seal hereinbefore mentioned is affixed to it, be examined by the Minister of Justice, who, if he finds it conformable to law, shall certify accordingly; and such patent or instrument may be signed and the seal affixed thereto, and being duly registered shall avail to the grantee thereof, and be delivered to him.

19. Whenever any patent shall be deemed defective or in operative by reason of insufficient description or specification, or by reason of the patentee claiming more than he had a right to claim as new, but at the same time it appears that the error arose from inadvertence, accident, or mistake, without any fraudulent or deceptive intention, the Commissioner may, upon the surrender of such patent, and the payment of the further fee hereinafter provided, cause a new patent in accordance with an amended description and specification to be made by such patentee, to be issued to him for the same invention or discovery for any part or the whole of the then unexpired residue of the five years' period for which the original patent was or might have been, as hereinbefore directed, granted. In case of the death of the original patentee, or of his having assigned the patent, a like right shall vest in his assignee, or legal representative; the new patent, and the amended description and specification shall have the same effect in law, on the trial of any action thereafter commenced for any cause subsequently accruing, as if the same had been originally filed in such corrected form before the issue of the original patent.

(To be continued).

A statue of Goethe in Munich will be uncovered on August 20, the 120th anniversary of the poet's birth.

IMPROVEMENTS IN LOOMS FOR WEAVING.

THE invention illustrated in the annexed engraving relates to the picking motion or the means of picking the shuttles in plain looms for weaving. It has been patented by Mr. Priestly and Mr. Deighton, of Bradford, York, whose object is to dispense with the picker spindles now employed (and which require lubrication), and thereby avoid the grease spots which are so frequently produced on the fabric while being woven, by the action of the pickers throwing off the lubricant from the said spindles upon the fabric. To accomplish this object a slot hole is formed in the bottom of each shuttle box, and the shank of the picker is formed to slide freely in the slot with a T head or projection under the box to prevent the picker coming out of the slot when the loom is in action. Ordinary upright picking sticks are used, which are hinged in line with the axis of the lay or lathe swords, and they project upward through the slots of the boxes, and also through slots formed in the pickers. Motion is given to the picking sticks by horizontal shafts actuated by tappets fixed on the low shaft of the loom, the shafts having levers thereon connected by adjustable metallic rods, jointed to allow the required duplex motion of the picking sticks.

Fig. 1 of our engraving represents an end elevation, and fig. 2 part of the front elevation of one end or a portion of the loom. A is the shuttle box, B the picker, C the picking stick which is hinged on the axis D of the lathe, E the horizontal shaft which is operated by an ordinary tappet F fixed on the low shaft of the loom, G is a lever fixed on the shaft E, and is connected by universal joints to an adjustable link or rod H, which connects it to the picking stick, and by which motion is communicated thereto. The picking stick passes through a slot formed in the bottom of the shuttle box, and also through a slot made in the picker. These parts are shown in detail at fig. 3, which is a cross section, and fig. 4, which is a longitudinal section of the box and picker, with a portion of the picking stick drawn to a larger scale. Figs. 5, 6, and 7 are three views of the picker, showing its construction for this purpose, where it will be seen that the shank is formed with a T end, or flanged to fit under the box bottom to prevent the picker from being lifted out of place by the action of the picking stick. It will be also seen, on reference to fig. 4, that the box bottom is of varying thickness, or that the under side is inclined, and a parallel groove is formed underneath by a pair of flanges to guide and give the picker a slight lift off the box bottom in picking, which is found requisite for driving the shuttle properly across the loom.

APPARATUS FOR DISCHARGING ORDNANCE.

WHEN a piece of ordnance is discharged by means of a vent which is left open during the explosion, flame and gases resulting from the explosion rush from the bore of the gun into the vent passage; the vent thus becomes enlarged, and the bore of the gun close to where the vent enters becomes starred or cracked, and the gun often ultimately becomes unserviceable from this cause alone. To avoid this injury to the vent passage, Mr. J. Vavasseur, of the London Ordnance Works, Bear-lane, Southwark, has recently patented an invention which provides for the firing of the charge whilst the vent is closed, in the following manner:—He introduces into the outer end of the vent, which is chambered, a capsule like the case of a cartridge for a breech-loading rifle. This capsule is provided with a percussion priming, and is loaded with a charge of explosive material sufficient to produce the volume of flame required. The capsule is held in the chamber of the vent, so that it may not blow back on firing, by means of a cover to the vent strong enough to resist the pressure of the gas. This cover is also fitted with a striker for exploding the priming of the capsule. The cover slides from one side on to the head of the ventpiece so as to allow the capsule to be withdrawn.

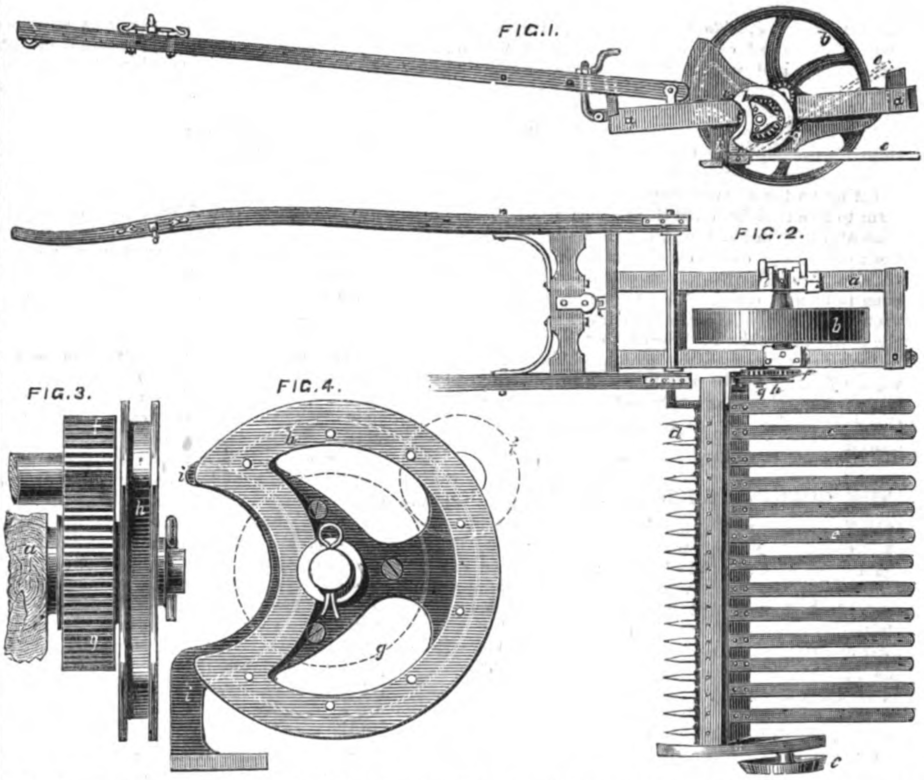
In our engraving, fig. 1 is a longitudinal section of the apparatus, together with a portion of the piece of ordnance to which it is fixed; the apparatus is also shown in plan at figs. 2 and 3. In fig. 2 the vent is covered, and in fig. 3 it is exposed. *a* is a ventpiece, which is screwed, as is shown, into a passage formed for it in the gun; it has a head a^1 of a dovetail form, in the centre of which is a cavity or chamber a^2 to receive a capsule. This chamber is formed somewhat like the cartridge chamber at the rear end of the barrel of a breech-loading rifle or fowling piece, and it is fitted with an extractor a^3. The extractor is more clearly shown in fig. 4, which is a transverse section of a part of the apparatus. The tail of the extractor is formed into a thumbpiece, as is shown at fig. 5. The chamber a^2 receives a metallic capsule charged with powder or other suitable explosive substance, and provided at its base with a percussion cap. The capsule is shown at fig. 6. *b* is a cover to secure the capsule in its chamber. This cover is able to turn on the centre pin b^1 carried by an arm fixed to the ventpiece *a*, and it fits to the dovetailed head of the ventpiece. By adapting the cover to the head of the ventpiece in this way, sufficient rigidity is attained to withstand the great strain which comes on the cover when the piece is fired. The cover is turned to one side, as is shown in fig. 3, to uncover the chamber a^2 for the introduction of the capsule, and, when the capsule has been inserted and the cover is replaced, the striker b^2 which the cover carries stands vertically over the capsule, so that, when forced down, it strikes it at the centre of its base, where the fulminator is situate. The striker is a pin with a flange upon it fitted into a cavity in a screw plug b^3 which the cover carries, and it is there secured by cap b^4. A spiral spring holds the striker up off the capsule until it is forced down by the hammer. Each time that a capsule is inserted and the cover is brought over it, the screw plug is set down so as to bind the capsule in its place.

Fig. 7 shows the spanner which is used to work the screw plug. The hammer *c* turns at c^1 on a pin carried by the cover *b*. A lanyard is attached to the hammer *c*, and when it is desired to fire the piece by a sudden pull on the lanyard, the hammer is made to descend on the striker and explode the capsule. b^5 is a stop screw fixed in the cover *b*; its end enters a groove in the ventpiece *a*, so as to limit the motion of the cover to the distance required. a^3 shows the extractor and the way in which it is applied; it consists of a bent lever fitted in a recess in the face of the head a^1, and turning on a centre. On one end of the lever, the flange of the capsule rests; the other is widened out to form a thumbpiece, and is pushed down when the capsule is to be extracted; a spring returns the extractor to its place. By the combination with the vent of the cannon of an extracting instrument such as we have described, the capsule after firing is readily withdrawn from the vent, an operation which otherwise would be difficult.

The capsule is shown to an enlarged scale at fig. 6. The tubular part of the capsule is made of copper; it is forced on to an iron disc containing a stout percussion cap, and having a projection on to which the cap is driven by the blow of the striker. The tube of the capsule contains a small charge of powder enclosed by a paper wad. By the use of this invention, not only is the rapid wear of the vent prevented, but the necessity of serving the vent or stopping with the thumb during loading is avoided, and all chances of accident arising from this operation being imperfectly performed are removed. In cast-iron guns it will not be necessary to have a vent tube passing through the metal of the gun; the vent for the greater part of its length may be simply drilled in the gun itself.

REAPING MACHINE.

BY MR. R. NORFOLK.



IMPROVED REAPING MACHINE.

IN reaping machines of the present construction, the platform on which the corn is collected has been raised and lowered by the attendant acting on a treadle. The invention illustrated in the annexed engraving consists in performing these operations by self-acting machinery actuated from the driving wheel of the machine, whereby not only is the labour reduced but the work is performed with more regularity than heretofore. This invention has been patented by Mr. Richard Norfolk, the managing director of the Beverley Iron Company, and was exhibited at the Manchester Show. To the driving wheel or its axle is fixed a toothed wheel gearing into another wheel, to which is attached a cam, which acts on a lever projecting from the platform. The cam is made with a long dwell to hold the platform up while the corn is accumulating upon it, and with a recess to allow the platform to drop suddenly when a sufficient quantity of corn for making a sheaf has been cut. The toothed wheels can be changed so as to vary the rotary speed of the cam, according to the state of the crop or to the size of the sheaf.

Fig. 1 in our engraving is an elevation and fig. 2 a plan of a reaping machine, to which Mr. Norfolk's improvements are applied, fig. 3 is an edge view, and fig. 4 an elevation of the machinery drawn to a larger scale. In figs. 1 and 2 *a* is the framework of the machine, *b* the driving wheel, and *c* the outer supporting wheel, revolving on a stud fixed to the frame of the cutters *d*. These parts of the machine are made in the usual manner. *e* is the platform on which the corn is collected; this platform is hinged to the framework, as usual, but instead of being raised and lowered by the attendant acting on a treadle, as heretofore, it is raised and lowered by self-acting

machinery in the following manner:—To the driving wheel b, or to its axle, is fixed the toothed wheel f (seen best in figs. 3 and 4), gearing into the wheel g, which is mounted on a stud fixed to the framework a. To the boss of the wheel g is fixed the grooved cam h, which is made with a long dwell, and with a recess corresponding in shape to the curved lever i, which is fixed to the rail of the platform e.

The engravings represent the parts in the positions they occupy when the platform is down, but as the machine progresses over the field the cam h, acting on the curved lever i, causes the platform to rise rapidly until it assumes the position shown in dots in fig. 1, and it will be held in this position by the dwell on the cam h, during the time required for the accumulation of sufficient corn to form a sheaf. The recess in the cam h then again comes opposite the curved lever i, and the platform is then at liberty to fall rapidly, to deposit the corn on to the ground. The toothed wheels f and g are or may be made to be changed so as to vary the rotary speed of the cam h to suit the state of the crop or the size of the sheaf required.

THE QUEKETT MICROSCOPICAL CLUB.

THE fourth annual general meeting of the above society was held, on Friday evening last, in the library of University College; Mr. Arthur E. Durham, president, in the chair. A report was read which showed that 142 members had been elected since the last annual meeting, making a total of 512. The treasurer's report showed that the finances were in a very satisfactory condition. In vacating the chair, which he had filled for two years, the President delivered a highly impressive address, which was listened to with marked attention throughout. The following gentlemen were elected to fill the offices named for the ensuing year:—For President—Mr. P. Le Neve Foster. For Vice-Presidents—Dr. R. Braithwaite, Mr. W. M. Bywater, Mr. A. E. Durham, Mr. H. F. Hailes. For Members of Committee—Mr. T. Crooke, Mr. B. T. Lowne, Mr. S. J. M'Intire, Dr. J. Matthews. For Treasurer—Mr. R. Hardwicke. For Hon. Secretary—Mr. T. Charters White. For Hon. Secretary for Foreign Correspondents—Mr. M. C. Cooke. A paper on the Ratio-micro-polariscope, by Mr. James J. Field, its inventor, was read, at the conclusion of which the instrument was exhibited. Ten new members were elected; after which the proceedings terminated.

A NEW ASTRONOMICAL SOCIETY.

MR. WILLIAM F. DENNING, of Ashley-road, Bristol, has succeeded in forming "a society of gentlemen possessing astronomical instruments, for securing concerted observation of interesting astronomical phenomena." Amongst the list of members are the names of six fellows of the Royal Astronomical Society, including Mr. W. R. Birt, one of our leading authorities on lunar matters; and Mr. A. Brothers, the author of a very excellent catalogue of binary stars, and numerous valuable papers on celestial photography. The affairs of the society are managed by a president, treasurer, and secretary, and a committee of five members. The Rev. R. E. Hoppell, M.A., LL.D., F.R.A.S., of South Shields, is the president; Mr. William F. Denning, of Ashley-road, Bristol, is the treasurer and secretary; while the committee consists of gentlemen whose names are well known in connection with science. The society now consists of twenty-six members, and, if energetically carried on, will be of great service in aiding the spread of practical astronomy.

AERONAUTICAL SOCIETY OF GREAT BRITAIN.

(Continued from page 64.)

I HAVE by me here some specimens of metallic foils; that of aluminium is so light and strong that a tubular boiler or generating apparatus made of it would weigh so little—I fear to say how little, lest it should be thought incredible, and there are several liquids, such as muriatic ether, ammonia, and carbonic acid that boil at so low a temperature as not to require any fuel to evaporate them; which evaporation may take place in thin vulcanized india-rubber tubes strengthened by external coils of thread or wire. All these fluids, in passing from the liquid into a gaseous form, produce an intense cold, which cold is capable of being utilized as a source of power just as so much heat in an air engine; and this is independent of the power obtained from their self-evaporation before alluded to. Excepting, however, for experiment, they are not so economical as steam or heated air, for in dealing with this latter we have only to take account of the weight of fuel to be carried; for steam is capable of being condensed, after doing its duty, and used over again, and the weight of fuel is less than a tithe of that of the water evaporated by it. I have on a former occasion described how very light engines could be constructed of india-rubber cloth on the bellows principle, but even these are not absolutely necessary. It is true, that to lift, say, 32,000lb. only 1ft. high in a minute, which is a horse's power, a heavy massive engine would be required; but to raise or drive 1lb. through a space of 32,000ft. in a minute, which is the same thing, only a very light engine of the ordinary kind is necessary, the weight being converted into velocity, and, fortunately, such a quick-acting engine is the only one adapted for aerial navigation.

But a word, in conclusion, on balloons. The question is often asked why they cannot be steered. The reply is, they can be both propelled and steered in a calm, like a steam ship, the only difference being that the balloon is supported by a fluid which generally moves more than 20 miles an hour, whilst the ship rests on a fluid that rarely moves more than three miles an hour. It is needless to say that if the circumstances were reversed, the steam ship would be as much at the mercy of the tides as the balloon is now at that of the wind; and so would a ship be at the mercy of the wind, were it not for its greater specific gravity; and a bird, too, if buoyed up by air cells, which, I regret to say, is the all but general opinion. I have scarcely ever had occasion to allude to the possibility of flying without receiving in reply the stereotyped remark. "Ah, but you forget that a bird has air cells," as if air cells were not the easiest things in the world to make. And what is the balloon itself but a huge air cell? Something practical, however, in the way of locomotion, I think, may even be accomplished with balloons. Although we cannot by mere drift proceed from point to point, we can from line to line. Taking advantage, therefore, of the trade winds, I do not see why a balloon could not be easily wafted from the west coast of Africa across the Atlantic to South America, and the voyage afterwards continued to the East Indies. As steam navigation and railways become extended over the world, a person may make the greater part of a long journey in a balloon, thus securing an agreeable temperature, even in a burning zone, and correct or complete the journey by some more certain means of conveyance. But with very little motive power a considerable deviation in its course could be effected—probably as much as 90deg.; and if a drag were employed to retard the motion of the balloon when passing over the sea, the wind itself would then be available for creating a diversion, either by acting directly on a sail, or turning a wind-wheel to drive a propeller.

Mr. Glaisher said that, as Mr. Brown had made reference to several materials for boilers so light that he would not like to say, he would ask Mr. Brown to state approximately the weight and the pressure per square inch.

Mr. Brown produced a slip of aluminium beaten to the thinness of tinfoil.

Mr. Glaisher suggested that Mr. Brown should take steps to find out the weight of boiler with the pressure per square inch in one atmosphere or two atmospheres. He made this remark because, when he occupied the chair at the last meeting, he heard a gentlemen talking of two or three hundred miles an hour, when they could not even rise from the ground. He had, therefore, called attention to the necessity of taking the first step rather than to what might be done afterwards. Mr. Brown had referred to the very thing wanted—a light engine with very great power. This was what they wanted in their present state of, he was going to say, knowledge, but he would rather say want of knowledge.

Mr. Moy said he had constructed a boiler of 6½lb. weight, which would give him half-a-horse power, and he thought that he could make a boiler one-third of that weight with the same power. The present boiler was not quite sufficient for his flying machine to go up with, and he wanted to make a machine which would prove a success. The breaking power of a piece of brass one-eighth of an inch wide is eight tons, and he was sure that was ample for anything wanted.

Mr. Glaisher: Mr. Brown speaks of a boiler which would not even weigh a pound.

Mr. Brown: Yes, it would weigh within the pound. I must say I have not tested the strength by experiment, but I have no hesitation in saying that it would be far lighter than any other boiler ever dreamt of.

The Chairman: I should like to ask Mr. Brown if he has taken into consideration the extreme difficulty of working aluminium. It is almost impossible to solder it.

Mr. Brown acknowledged the difficulty.

Mr. Olrick, C.E., remarked that there were several points on which he could not agree with the writer of the paper, and if he happened to know that those points were not correct, he would not be doing his duty to the Society if he did not point them out. His first objection was that the power was underneath, and he doubted whether the machine and the carriages which it was to push would take the same direction. The one might aim for the south-east and the other for the north-west. Mr. Brown had proposed to make a boiler from tinfoil. If any engineer proposed to make a boiler from that stuff, he would never get a boiler maker in England to entertain any scheme of the kind. He had made 200 boilers of light construction, but Mr. Brown would not be able to rivet his material together, or to get it caulked. He was afraid it was impossible to do it; and, as to strength, it would be equally deceptive, for although you might reduce the thickness of your plates to a minimum with the best steel that could be made, he could not go so far as to use tinfoil, with neither strength nor toughness. (Mr. Brearey here reminded the speaker that the specimen submitted by Mr. Brown was aluminium and not tinfoil). He had great objection to the use of steel for boilers, for he knew how treacherous it was, and how much he might be on the wrong side in his profit and loss account. He knew of about 50 steam boilers working at a pressure of about 150lb. or 180lb., which appeared to him was sufficient for practical purposes. Some of these he had tested to 250lb. per square inch. He ought to mention particularly the Bolton Steel and Iron Company, who had taken immense pains to produce a kind of steel that can be used with safety. Mr. Moy had remarked ⅛in. thickness of brass would stand a pressure of eight tons. Eight times that would make one inch of brass stand a tensile strain of 64 tons. He was afraid that must be divided by four for actual fact. The best steel used for boiler making would only stand a tensile strain of 34 tons per square inch. As to Mr. Brown's theory, and the wafting of a balloon from Africa to America, he was of opinion that most of them would hold their lives too dear to make the experiment. No doubt it would be better to have a flying machine than a balloon, and he could assure them that whenever such is invented light engines will be forthcoming.

Mr. Moy said that he spoke of the breaking strain of brass. As to constructing a flying machine, they ought first to make a model that would sustain itself for five minutes, in order to then show engineers what they could do.

Mr. Brown observed that the material he had brought was hard and light, and not like tinfoil. It did not break nor crack, and it was, to his mind, the best thing they could have. The chief objection to it was that suggested to it by the chairman, namely, that it was not easily fastened.

Mr. Olrick: It is perfectly impossible to make a boiler of that stuff, which you could rivet or caulk, or which would sustain any steam pressure for practical purposes.

Mr. Wenham stated that there had been an aluminium boiler made with the top and bottom screwed on. It was very light indeed. It was not exactly a tubular boiler. Steam was generated by charcoal, and it was said to be able to stand a pressure of between 200lb. and 300lb. per square inch.

Mr. R. Sheward, engineer, read the next paper upon the construction of an aerial machine. The author proposed to construct this machine in the following manner:—An oval slab, 60ft. in length by 40ft. in breadth, is to be made airtight and sufficiently rigid to sustain the required weight. Above and below this is to be attached a fabric strong enough to bear a moderate degree of external and internal pressure. This fabric, both on the upper and lower side of the slab, is to be porous, or perforated with a number of small apertures. By means of a steam engine in a car suspended beneath the slab, and a suitable exhausting and blowing arrangement, air is withdrawn from beneath the fabric above the slab, and, entering through the upper pores, gives a rising tendency. Air exhausted from above is forced into a compartment below, and, being injected downwards through the pores with some velocity,

by its reaction forces the machine upwards. By the combined action of these two forces, the author expects to gain an ascending power equal to about two ounces per square inch. The propulsion is proposed to be effected by the ejection of air in a backward direction, and the steering to be performed by means of a rudder.

In a conversation with Mr. Quartermain, Mr. Sheward said he anticipated getting a sustaining power of 7 tons from a surface of 60ft. by 40ft.

The Chairman expressed his belief of the entire impossibility of working the machine in the manner proposed, and he suggested that a trial with a few sheets of paper would convince Mr. Sheward of the impracticability of his scheme.

Mr. Wenham and Mr. Olrick took the same view, the latter suggesting, if the writer of the paper had more experience, he would not stumble over the first elementary steps.

(To be continued.)

CAST-IRON ARCHES.

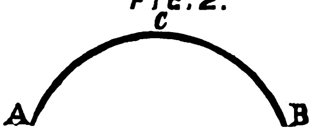
ANYONE who attentively takes into consideration the fact that the existing Southwark Bridge has the largest span of all similar structures crossing the river, cannot but be surprised that the principle of construction embodied in its erection should not have been more extensively developed. It is not to be understood that it is a matter of astonishment that all the bridges over the Thames are not like unto Southwark Bridge, but that the use of cast-iron arches is comparatively so restricted. The excessive rise demanded by an arch having a span of 260ft., which is the dimension of the centre span of Southwark Bridge, would altogether preclude the idea of employing a similar example for a new bridge over the river. Besides, although it has the merit, so far as size is concerned, of being the largest arched bridge in the world, yet it is by no means a favourable specimen of either engineering or architectural construction. It has not the slightest pretence to architectural beauty. The material is not only greatly in excess of the quantity necessary, but is moreover unscientifically and unskilfully distributed. Nothwithstanding that all this constitutes an unanswerable objection against the erection of another Southwark Bridge, it does not in any sense form a tenable argument against the adoption of the principle of cast-iron arches in the abstract. It is idle to talk of their not being safe. Take the South-Western Railway, for instance; nearly all the bridges carrying it over the main thoroughfares in the southern parts of London are composed of cast-iron arches. Westminster Bridge-road, Lambeth-road, South Lambeth-road, and numerous others have been traversed for years by trains running over bridges of cast-iron arches, some of which reach a span of 70ft., and they are to all appearance as safe as when they were originally erected. The true cause for the partial abandonment of the cast-iron arch type of erection is to be found in two circumstances. One is that some examples, not so much of the actual arch systems of the cast-iron girder, failed very conclusively—and, in fact, disastrously—years ago. The other is that most of the early engineers contemplated building bridges of enormous spans, for which a material such as cast iron is not well adapted. It was never for a moment considered that the failure of some of the cast-iron girders was due to ignorance on the part of the designer, and a complete want of scientific knowledge respecting the manner in which the strains act, and the proper proportions that ought to be given to the various parts. Not at all. Cast iron was at once voted by the profession as insecure, fickle, and treacherous material on something of the same ground that dictates the adage, "Give a dog a bad name and hang him."

It must not be supposed from the foregoing observations that we are about to advocate the wholesale adoption of cast-iron arches and girders, and that we regard them as suitable to every condition of span and rate of loading. Quite the contrary. But we do maintain that cast iron, like all other materials, has its legitimate, useful, and economical use, from which the idle fears of many professional men have endeavoured to exclude it. That it is not suitable for large railway bridges, with spans of 300ft. or 400ft., we readily acknowledge, but at the present time long span bridges are regarded in the light of an occasional necessity, but never of a desirable result. The mania for bridges of enormous span has completely died out, it having been long since demonstrated that a multiplicity of spans of average dimensions is by far the most economical method in the long run of bridging over an intervening space. Colonel Kennedy was the first engineer who broached the theory of the economy of small spans, and practically carried it out over 250 miles of line in the north-western part of India. He assumed 60ft. as the maximum span, which no doubt is too small, and might be safely increased to 80ft. without any risk of entrenching upon the principle of economy. Bridges of small span having, to speak fashionably, "come in again," it is a subject deserving serious consideration whether cast iron may not be employed instead of wrought, with great advantage on the score of economy and simplicity. A glance at the recent bridges thrown across the Thames, whether for railway or road traffic, demonstrates beyond a doubt that spans of moderate dimension are more in accordance with the ideas of the present race of engineers than they were in the days of Brunel and Stephenson. It has been shown that a few piers of moderate proportions produce no injurious effect upon the navigation of the river, and their expense is very much less than a long unsupported superstructure. The cost of a bridge increases in a far higher ratio than that of the mere span, which is the real reason that renders all long span bridges of so expensive a character. All engineers agree that the most economical manner in which to employ cast iron is that which allows of its compressive resistance only to be called into play. Practically, the ultimate resistance of good sound cast iron to compression may be taken at 50 tons per square inch, while that of wrought iron cannot safely be assumed to exceed 18 tons per square inch of sectional area. On the other hand, the tensile strength of wrought iron is rarely beyond 22 tons, and that of cast iron cannot be estimated at more than 8 tons per same unit of area. It is for this reason that cast iron is so very unsuitable a material for constructive purposes where heavy strains of a tensile nature are brought upon the design. On the other hand, owing to its very high resisting power to a strain of compression, it is admirably adapted for situations where those strains are likely to occur. It is, therefore, peculiarly well suited for the arch type of construction, where compressive strains prevail. Not only is it well adapted for erections of this character, by reason of its great compressive strength, but the large masses in which the various parts can be obtained, the fewness of their number, and the ease and simplicity with which they can be put together, render it an exceedingly convenient material for the purpose. Instead of the almost infinite number of rivets that are required to put together even the smallest specimen of a wrought-iron girder, a few bolts suffice to make the necessary joints, and a vast amount of time and labour is therefore saved. Moreover, in consequence of its greater inherent weight, it is better able to resist vibration, and can dispense with the large quantity of extra stiffening material which is a *sine quâ non* with wrought-iron structures, whether they be roofs or bridges.

The theoretrical distribution of the strains upon the arch is also more favourable to the employment of cast iron in that than in any other form of construction. In the flanges of a horizontal girder, whether lattice or solid-sided, the strains accumulate gradually from the abutments or supports A B to the centre C, so that the sectional area of the flanges must be increased in the same direction. This increase of area is obtained in the manner represented in fig. 1, where additional plates are riveted

FIG. 1.

FIG. 2.



together according as the centre of the flange is reached. In the arched form, on the contrary, the strains, which are all of a compressive nature, increase from the centre C towards the abutments A B, but the difference is not so considerable as in the horizontal girder. The gradual increase of the strain in the arch is shown in fig. 2 by the uneven thickness of the black line. Practically, the advantage arising from this theoretical distribution of strain in the arch, so far as cast iron is concerned, is that the only difference that need be made in the sectional area of the girder or rib can be effected by increasing the depth towards the springing. Those who are aware how important it is that large castings should not depart from a symmetrical form will at once recognize the merits of the arch. Girders for cast-iron arches are generally termed ribs, as they are placed much closer together than is the practice in ordinary bridge construction. They are usually of the section represented in fig. 3, their depth being increased, as already mentioned, from the crown towards the springings. Owing to the greater thickness of their web, they are much stiffer than a plate or lattice girder, and require no absolute stiffening, although they must be braced together in order to give the whole structure the requisite amount of rigidity. A distinction should always be observed between stiffening and bracing. The former has reference, strictly speaking, to only particular parts of a structure; the latter to the whole. There are two simple equations which will suffice for determining the strains upon a cast-iron arch, and the quantity of metal required at the crown and the springing. To consider the crown first. Suppose we have to ascertain the quantity of material, or the sectional area required at the crown for the rib of a cast-iron arch which has a span of 80ft., and a rise of 8ft. Let the share of the whole weight upon the bridge, which is carried upon one girder, be equal to W, equal to 20 tons. Putting L for the span, R for the rise, and S for the strain at the crown, we have

FIG. 3.

$$S = \frac{W \times L}{8 \times R} = \frac{20 \times 80}{8 \times 8} = 25 \text{ tons.}$$

As cast iron will safely stand 6 tons of compressive strain per square inch, we obtain the number of square inches in the rib at the crown by dividing the strain by that number. Consequently, the number of inches of metal equals $\frac{25}{6} = 4{\cdot}166$. Calling S^1 the strain at the abutments, or springing of the arch, we have

$$S^1 = \frac{W}{2}\sqrt{1 + \frac{L^2}{16 \times R^2}}$$

Substituting in the equation the values of the letters, we have

$$S^1 = 10\sqrt{1 + \frac{80 \times 80}{16 \times 8 \times 8}} = 10\sqrt{1 + 6{\cdot}166}$$

= 27 tons in round numbers. It is thus seen that in a small example there is very little difference in the amount of the strain at the crown and the springing. In this present case, the practical method of proceeding would be to make the area of the rib equal to five square inches, and the section and depth will thus be constant throughout the whole arch. Where the bridge is of large dimensions, the depth will have to be increased, as may be seen by a glance at either the Victoria Bridge carrying the London, Chatham and Dover Railway over the Thames at Battersea, or at the new Blackfriars Bridge, which is rapidly approaching completion. The erection of one new bridge over our metropolitan river draws attention to the fact that many others are wanted, and there is not the slightest doubt but that with spans of about 150ft. they could be more economically constructed of cast iron than of other material. The foundations also might be "got in" in a less troublesome and costly manner than what appears to be the organized method for road and street bridges. In fact, there is no reason why we should not have a road bridge over the Thames, handsomely, solidly, and securely built, altogether of cast iron, both piers and superstructure.—"Building News."

Legal Intelligence.

ROLLS COURT.

JULY 22.

CROSSLEY *v.* DIXON.

THIS was a suit instituted by the plaintiff, the well-known carpet manufacturer, to obtain certain royalties from the defendant in respect of a loom for the manufacture of carpets used by him, and which loom the plaintiffs alleged infringed four patents held by the plaintiffs for distinct portions of looms used in the manufacture of carpets. A large model had been constructed and placed in the yard of the Rolls Court for the purpose of enabling the Master of the Rolls to understand the points at issue between the parties.

His Lordship now decided that none of the details of the defendant's loom which the plaintiffs alleged to be an infringement of their patents were in fact so; but that, in his lordship's judgment, they were mechanical results which, although similar to the plaintiffs', had been arrived at by different processes. He therefore dismissed the plaintiffs' bill with costs, except certain costs occasioned by an improper contention on the part of the defendants.

Sir R. Bagallay, Mr. Jessel, Q.C., Mr. Grove, Q.C., Mr. Cracknall, and Mr. Aston appeared.

COURT OF CHANCERY.

JULY 26.

(Before Lord Justice GIFFARD.)

IN RE HORSLEY AND KNIGHTON'S PATENT.

IN this case, the Master of the Rolls a few days ago made an order to expunge an entry from the register of patents. An appeal was presented. The counsel for the respondents took the objection that the Patent Law Amendment Act of 1852, the 38th section of which gave the Master of the Rolls the jurisdiction to expunge the entry, gave no right of appeal from his decision.

Lord Justice Giffard held this to be a fatal objection, and dismissed the appeal with costs.

Sir R. Baggallay, Q.C., and Mr. Cracknall were for the appellant; Mr. Jessell, Q.C., Mr. E. Rodwell, and Mr. T. Aston, were for the respondent.

VICE-CHANCELLOR'S COURT.

JULY 27.

(Before Sir R. MALINS.)

PULVERMACHER *v.* HAMMOND AND ANOTHER.

This bill, filed some time ago for an injunction to restrain the defendants from advertising in a manner which might in any way interfere with the plaintiff's business, now came on to be heard as a short cause, the principal defendant (Barrow) having consented to a decree (not to contain the words "curative belts") for a perpetual injunction. The plaintiff not pressing for them, no order was made as to costs.

Mr. T. A. Roberts appeared for the plaintiff, and Mr. Graham Hastings for the defendants.

Correspondence.

STEERING GEAR.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—At the opening of the New Alexandra Dock, at King's Lynn, a notice of which appeared in your journal of the 9th instant, there was some delay experienced in getting the steamer "Mary" alongside the middle starth, owing to her steering, which was not of the best. This is a state of things that should not exist, and a disgrace to a maritime nation, in an age of improvements. Yet, it is very remarkable what little importance seems to be attached to the steering gear in general use in the mercantile marine of this country. Lloyd's specification for classing ships enters into every detail requisite for a first-class vessel, such as spars, cordage, anchors, cables, &c., but no allusion whatever is made to steering gear, leaving this most important matter entirely to the fancy of owners or builders. It may be supposed that when the lives and safety of thousands of human beings, sent daily adrift between a few boards, to buffet the winds and battle with the wild waves of the mighty deep, that great care and precaution would be taken to keep the helm of our ships under quick and proper control, and that the best appliances would be adopted for such a purpose. This, however, is not the case, and nine-tenths of the collisions and accidents that happen at sea is owing to bad steering from the slow action of the apparatus used, and the vessel not answering her helm as readily as she may be made to do if more care is taken in so vital a matter as the steering gear. Take the "Mary" as an instance; she is a splendid twin-screw steamer, of the best construction, and being a first-class boat, was engaged for the express purpose of carrying Royalty, yet it would appear that this vessel, so superior in every thing, seemed defective in the most essential matter—her steering; and it is frightful to think what the result may have been had a sudden squall overtaken her at that particular moment, when her steering was found defective.

It cannot be for want of inventive genius in this country that such a state of things exists; there are plenty of inventors, but as genius and poverty go together, no encouragement seems to be given to them, and it would appear that it is nobody's duty to test the inventions and improvements that are brought out, and to pronounce a judgment on the best and safest. At a recent conference of the Institution of Naval Architects, held at the rooms of the Society of Arts, there were exhibited plans, diagrams, and models of three patented inventions of steering gear; one was hydraulic, one steam, and the other Skinner's vertical screw. The two former were good, and lost nothing in power, but seemed rather complicated and expensive machinery, and more fit for large vessels of war than for merchant ships. The vertical screw, however, seemed compact, and well adapted for any size of vessel, from a yacht to the "Great Eastern" herself. It was said to be powerful and quick in action, and suitable for steam as well as sailing vessels. These inventions, which may be considered the latest and best improvements in steering, do not seem even known to builders. They have been fitted by Government on some of H.M. ships, and nothing further is heard of them, because the Admiralty don't publish reports of their tests for the benefit of the public. Messrs. Miller and Co., it would appear, are fitting Skinner's vertical screw to a 3,000 tons steam ship, of 400ft. long, just launched by them at Liverpool. This, it is true, will be a good test of this particular apparatus; but why don't H.M.'s Government or Lloyd's give every invention of this kind a fair and good trial, and report the result to the world at large, as a guide to shipowners of the safest gear to adopt for their vessels? At present it would appear that shipowners leave the matter in the hands of shipbuilders, and these latter use whatever gear is cheapest and most profitable to themselves; in the meantime, collisions will happen, and accidents take place, and while owners get compensation from insurance companies, no notice is taken of the sacrifice of human life. This is a serious subject, and demands much consideration from the Government, the merchants, and the shipbuilders of one of the first maritime nations in the world.—I am, Sir, yours, &c., M.

THE GUNPOWDER PILE DRIVER.

SIR,—Frequently finding valuable information in your magazine, which appears regularly at the reading room of our Franklin Institute, Philadelphia, I send you a few lines descriptive of a new pile driver lately invented by our townsman, Mr. Thomas Shaw. The machine consists of a scaffold and ladder mounted on rollers for change of position, and the top stayed at the cardinal points by ropes similar to most other perpendicular rams. The hammer is a cylindrical mass of iron, having a projecting tongue or plunger in its lower end, moving in a perpendicular frame of the same metal, which frame may be widened or narrowed by a lever in the hands of the operator, in order either to grasp or let fall the hammer. The head of the pile is covered with a heavy cast-iron cap, which sits firmly in its place without fastening upon the log, having in its centre a carefully bored chamber, into which the plunger of the hammer fits airtight. A very small charge of gunpowder, made up in a cartridge, is thrown into the chamber, and is exploded by the compressed air acted on by the plunger at the moment when the hammer strikes the upper surface of the cap; which explosion greatly promotes the driving of the pile, and also throws up the hammer preparatory for the next blow.

The following report of a recent experiment will give a more definite idea of the invention. The spot selected was on the premises of Mr. J. W. Lynn, the celebrated shipbuilder, adjoining the United States Navy Yard. The soil consists of layers of foundry slag, waste bricks, coal ashes, and live oak and yellow pine chips, some 12ft. or 15ft. thick, resting on the tough clay of the original Delaware Marsh. The operations were conducted by the inventor (Mr. Shaw), with a skilled assistant to supply the cartridges, in the presence of Chief Engineer Wood, United States Navy, and other officers of the Service, Mr. Lynn, and other builders and machinists.

Height of scaffold, 48ft.; length of pile, 32ft.; diameter of pile, 1ft.; weight of hammer, 675lb.; weight of cap, 1,200lb.; size of plunger, 4½in. by 18in.; average drop of hammer, 9ft.; charge of gunpowder, ½oz.

A speed of twenty strokes per minute was soon attained, the pile sinking perceptibly with varying progress from 3in. to 8in. at a blow. The following comparisons were next made:—1. With the hammer falling 8ft., no gunpowder used, and the plunger not allowed to enter the air chamber, the pile sank 13-16ths of an inch. 2. With same fall of hammer, no gunpowder, but the plunger going home in the air chamber, the pile sank 1 10-16ths inch. 3. With same fall of hammer, and a cartridge of ½oz. of gunpowder exploded by the plunger, the pile sank 4 5-8ths inches.

No. 1 exhibits the full effect of a common ram of similar weight. No. 2, by the compressed air shows just double the former result. While No. 3, showing explosion combined with the former forces, gives nearly six times the effect of No. 1.

Under a quite moderate speed of strokes, the pile sunk 10½ft. in 1¼ minute. The speed was next raised to that of forty-eight strokes per minute, a part of which time the controlling lever was not used, the hammer slipping up and down between the guides, timing itself by the supply of cartridges alone. After the pile had been driven down some 30ft., the cap was lifted, and the head of the log was found uninjured and almost without an indentation. Without stoppages for measurement and conference, the pile could have been driven home in three minutes.

This trial had been preceded by various others, each producing a similar general result. All parties present expressed high gratification at the performance of the machine, and full confidence in the value of the invention, the rapidity and perfectness of its execution being pronounced unprecedented.

It exhibits explosive force, hitherto almost intractable, so completely under control that the inventor has determined to apply the principle to the heaviest metal forging, a practical test of which may be expected soon.—I am, Sir, yours, &c.,

Philadelphia, July 10. HECTOR ORR.

WHEEL-MOULDING MACHINE.

SIR,—Referring to the description of Scott's moulding machine for toothed wheels, in the number of the MECHANICS' MAGAZINE for July 9, I beg to inform you that such a machine as that described was patented thirty years ago, the patent being dated October 11, 1839, and granted by the Prussian Government to the inventor, Mr. T. G. Hofman, the leading engineer of Ruffer's large machine manufactory at Breslau. Since that time up to the present, this machine has been in practical use in the foundry of the above-named establishment, where it may be seen at work every day.—I am, Sir, yours, &c., KAYSER,

Breslau, July 20. Civil Engineer.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscriber of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Naval, Military, and Gunnery Items.

THE daring attempt which was made early in the morning of the 19th inst. to abstract an iron chest, containing upwards of £4,700, from the paymaster's office on board Her Majesty's ship "Octavia," at that time lying alongside the south jetty of the Portsmouth Dockyard, formed the subject of a lengthened investigation before the Portsmouth magistrates on Monday and Tuesday. The prisoners were committed for trial.

ACCORDING to "Punch," the following is something which requires to be overhauled:—The Naval School at New Cross has, according to the "Standard" (which appears to Mr. Punch to have made out its case), "succumbed to Bumbledom." A master who set himself against dirt, bullying, and, worse, who protected the young boys, and caused all to wash themselves, has been forced to resign. One defender of the Bumbles writes that "boys will be boys." We beg pardon, they are boys, and will be men, and it is to be wished that they should be humane and clean men, and not cruel and dirty men. But Bumble perhaps thinks that a naval cadet ought to be a naval cad.

WE have to announce the death of Vice-Admiral G. H. Seymour, C.B., and M.P. for the county Antrim, who died at Hampton Court Palace on Monday morning. He had only recently attained the rank of vice-admiral. The gallant officer prominently distinguished himself as commander of the "Wanderer" in the Yang-tse-Kiang in 1842; and after almost continuous employ was appointed captain of the "Cumberland," January 7, 1851. His commissions bore date as follows:—Lieutenant, June 27, 1838; commander, January 29, 1842; captain, May 27, 1844; rear-admiral, March 23, 1863; and by the recent death of Sir William Bowles he had been removed to the list of vice-admirals.

A MAN, who years ago was one of the notorieties of Europe, has just died at Brussels. His name is Cantillon. He was a serjeant in the Old Guard of Napoleon, and fought through the campaign of Waterloo, quitting the army after the capture of Paris. After the execution of Ney and Labedoyere thirty or forty of the non-commissioned officers of the Old Guard conceived the idea of assassinating Wellington, whom they regarded as the chief author of the evils that had befallen France. About the end of December, 1815, a pistol shot was fired at the duke in the streets of Paris, but missed him. Cantillon was suspected and tried, but the proof was not clear, and he was acquitted. It was to this man Napoleon left a legacy of £400, which was paid in 1823.

A SEVERE accident occurred to some Naval Reserve men last week on board Her Majesty's ship "Dauntless." It would seem that a party was practising at target exercise under the gunnery instructor, and, after some rounds had been fired, a gun went off just as the rammer was being withdrawn. One man had an arm broken, and was severely scorched; another was contused and slightly burnt, while a third was so much injured about the arms by the flame, that a fatal result is feared, although, strange enough, not a bone was broken. The man who served the vent had his thumb split, and it would from this circumstance seem that he must have done his duty too "tenderly."

UPON the subject of naval courts martial the "United Service Gazette" observes:—We have never felt or expressed any great confidence in the verdicts of these courts. Still, when their decisions are such as suit our purposes, we reserve to ourselves the right of quoting them. A court martial dismissed a young officer from his ship for nearly getting her on shore. He did not get her on shore, but saved her in the nick of time. Another officer got his ship on shore and did it completely, and was told not to do it again. We think that the punishment in the former case was extravagant, and cannot understand why the victim of it is thrust aside to half pay, while the hero of the other court martial is in active employment. The "Eclipse" scarcely touched the ground. The "Cadmus" stuck hard and fast. It may not have been the fault of anyone, but the lenient judgment which applies to one case may surely be applied to the other.

Miscellanea.

REPORTS from Lake Superior state that the production of iron in that district has been larger than ever this year.

FIFTY-THREE women clerks have just been placed on duty as copyists in the Patent Office, Washington—salary, 700 dols. per annum.

THE next annual congress of the Social Science Association is appointed to take place at Bristol, from September 29 to October 6 next.

ON Tuesday last the Royal Archæological Institute closed its summer meeting at Bury St. Edmunds, which has passed off successfully. Next year the institute will meet at Leicester.

THE Alabama and Chattanooga Railroad will, it is said, develope inexhaustible coal fields of a quality superior to any yet discovered south of the Ohio; it is also expected to open out vast deposits of hematite iron ore.

A CATALOGUE of the Royal Berlin Museums has just appeared in the English language under the title, "Special Catalogue of the Royal Museums at Berlin." It is divided into two parts, one for the old, the other for the new museum.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending July 24, was 3,809. Total number since the opening of the Museum, free daily (May 12, 1858), 1,608,693.

LARGE flocks of seagulls were off the estuary of the Tyne and the coast of Northumberland last week. A large number of them were young birds, and as they are now strictly preserved during the close time, they came quite in shore and were undisturbed, as no one dare fire a gun at them.

ABOUT 28 miles of the track of the New York and Newhaven Railroad were relaid last year with steel rails. About 2,800 tons of steel rails have been ordered for the renewal of the track during the present season; when these are all placed on the track, about one-half of the entire road will be laid with steel.

THE congress of directors of railways traversing Germany and Austria, or terminating in those countries, held its first sitting at Vienna last week. These companies possess 77 lines, the total length of which is about 18,750 miles, and the whole cost 250 millions of pounds sterling. Their rolling stock is composed of 6,000 locomotives, and more than 200,000 carriages, transporting annually 100 millions of individuals, and 1,500 tons of goods.

THE value of the exports of steam engines made from the United Kingdom has somewhat revived this year, having amounted to May 31 to £645,771 as compared with £569,953 in the corresponding period of 1868, and £778,038 in the corresponding period of 1867. The value of the steam engines—probably for the most part locomotives—sent to Russia has largely increased this year; on the other hand, there has been a rather material decrease in the case of British India.

A LARGE eagle, belonging to what is known in Scotland as the class Erne, was captured near Loch Tay last week. The bird, which measures 5ft. 4in. from top to tip of the wings, is a beautiful specimen of its class. It had been enjoying capital sport on the preserved waters of Loch Tay during a fortnight, and many unsuccessful attempts had been made to secure it. It was, however, ultimately taken in a trap skilfully set in a fallen tree at the western corner of the loch. No bait was used in the trap.

THE number of visitors to the South Kensington Museum during the week ending July 24, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 11,821; Meyrick and other galleries, 2,632; on Wednesday, Thursday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,865; Meyrick and other galleries, 243; total, 16,561. Average of corresponding week in former, years, 11,881. Total from opening of Museum, 8,641,437.

A JOURNAL of Lyons says:—In the districts of Revermont and Bugey very great complaints are made of the multitude of foxes, and in the Cote-d'Or of wolves and boars. At Vievy three penetrated the other night into a stable and destroyed 25 sheep. Great ravages had also been committed by those animals in the neighbouring communes. The wild boars make their appearance in troops; in one place as many as 10 were found ravaging a field of wheat. The farmers have the greatest difficulty in driving them away.

WE understand that arrangements have been made to enable working men to visit the Amsterdam International Exhibition at a very small outlay, and that by giving a fortnight's notice they may obtain excellent accommodation for a shilling a day from the exhibition committee. Baron Mackay has been in correspondence with the "Working Men's Club and Institute Union" on the subject, and the secretaries of that Society will afford every information.

AT the closing ordinary general meeting of the Royal Institute of British Architects, held on Monday, June 21, 1869, Mr. William Tite, M.P., President, in the chair, the following recommendations for membership were read:—John Edward Cox (Associate), of Warblington, Havant; Herbert Williams (Associate), of 52, Old Broad-street, E.C., as Fellows. H. Joseph Williams, of 52, Old Broad-street, E.C., as Associate. The following gentlemen were then balloted for, and declared to be duly elected:—James Tollery (Associate), of 13, Angel-court, Bank, as Fellow. Benjamin Adkins, of Faversham; John S. Nightingale, of 21, Parliament-street, S.W. as Associate.

THE Royal Horticultural Great Show at Manchester was the third experiment made by the Society of holding an exhibition in the provinces, and has been most successful. On the high-priced days the ground was thronged, and when the payment was reduced to a shilling vast numbers of operatives might be seen poring over ferns and vegetables, which were represented by such a collection as has seldom been seen even in the metropolis. The bands of the 1st Life Guards and the 68th Regiment performed selections of operatic and other music.

WITH the means of locomotion at present in use a tour round the world may be made in 80 days. The itinerary is as follows:—Paris to New York, 11 days; to San Francisco (rail), 7; Yokohama (steamer), 21; Hong-Kong (steamer), 6; Calcutta (steamer), 12; Bombay (rail), 3; Cairo (steamer and rail) 14; Cairo to Paris (steamer and rail), 6; total, 80. Of that immense route, the only portion on which steam is not used is about 140 miles between Allahabad and Bombay, and that interruption will shortly cease, as the works for completing the railway are being carried on actively.

DURING the progress of the works at Suez, M. Lesseps despatched a number of engineers to the Desert of Sahara to ascertain the exact difference between the level of that tract of country and the surface of the Red Sea. The surveying party on their return reported a declivity of 27 metres, which is presumed to become still greater further inland. M. Lesseps now suggests the possibility of letting the waters of the Red Sea into the interior of Africa by means of a canal, and thus converting this hitherto almost unexplored desert into a large inland lake, which would afford easy access to the fertile countries surrounding it. We wonder how the natives will like this.

THE British Museum has been enriched by the purchase of a bronze, found at Foggia, in Southern Italy, which is as remarkable for its beauty as for its almost perfect preservation and unusual size. Its subject is a naked boy at play. His little body all life and excitement, he lifts up two fingers of his left hand, while the outspread right is idden behind his back. The game he is engaged in is that of mora (tocca), as played in Italy to this day, the selfsame game which the Romans called micatio, and which in mediæval Germany was popular under the name of "Fingerlein snellen." It is played in different ways, the most common being that the two partners suddenly and simultaneously open their clenched fists and stretch out a certain number of fingers to be guessed and called out at once by the adversary.

THE amended bill to prohibit for a limited period the importation and to restrict and regulate the carriage of nitro-glycerine has been printed. So long as the Act shall be in force, it shall not be lawful for any person to import into any part of the United Kingdom from any other country or place any nitro-glycerine for any purpose whatever, or to sell any nitro-glycerine for any purpose whatever, except to workmen in his employ, or to carry nitro-glycerine along any public highway, canal, river, or navigation, except with such licence and under such regulations as provided in the Act. The penalty is a fine not exceeding £100, or 12 months' imprisonment. It is proposed that the Act shall come into operation on October 1 next.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—6
BUILDINGS AND BUILDING MATERIALS—13, 33
CHEMISTRY AND PHOTOGRAPHY—3984, 9, 22, 33
CULTIVATION OF THE SOIL, including agricultural implements and machines.—None.
ELECTRICAL APPARATUS.—23
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—3968, 3979, 3980, 3991, 2, 10
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—3978
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—3969, 3972, 3986, 3990, 7, 15, 16, 18, 34
GENERAL MACHINERY—3982, 3985, 1, 12, 19, 27
LIGHTING, HEATING, AND VENTILATING—3974
METALS, including apparatus for their manufacture—3971, 3983, 4, 18
MISCELLANEOUS—3970, 3973, 3978, 3, 5, 8, 17, 21, 24, 26, 29, 32
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—3977, 3939, 11
SHIPS AND BOATS, including their fittings—3988, 25
STEAM ENGINES—None.
WARFARE—3981, 3987, 14

3968 J. H. JOHNSON, Lincoln's Inn-fields. *Paper tubes*. (A communication). Dated December 30, 1868.

This consists in making, and marking with the maker's name or trade mark, or other letters, figures or devices by mechanical means, and in a continuous succession the paper tubes employed in the spinning of wool and other fibrous substances. These tubes are also produced in duplicate simultaneously. The paper from which the tubes are manufactured is fed into the machine in the form of a continuous band or strip, wound on a reel, and the duplicate mechanism is disposed in reverse directions, in order to admit of the strip being severed or cut into portions or sections, of such shape as will form when rolled or coiled tapered tubes, with a minimum waste of material. The strip previously cut to the requisite width and wound on a reel or roller is first conducted between a pair of printing rollers, or beneath a stamper, from which it receives the manufacturer's or other name, trade mark, or other device. The strip passes thence between a pair of feed rollers, having an intermittent motion for enabling the subsequent operation of cutting or severing to be performed. This operation consists in cutting or severing a length from the strip, of the form of a parallelogram of equal sides, by means of a rectilinear knife. Each parallelogram serves for the manufacture of two tubes, for which purpose it is divided by a second knife, called a "guillotine," into two parts of the same size, and of a trapezoidal contour, the shortest sides of which subsequently form the narrower ends of the tapered tubes, the non-parallel sides corresponding to the length of the tubes. In order to obtain the geometric development of the tube or truncated cone, it is necessary to cut in the form of two concentric arcs the two parallel sides of the trapezium, which is accomplished either by a pair of curved shears or by a cutting punch.—Patent completed.

3969 W. WINTER, Leeds. *Sewing machines.* Dated December 30, 1868.

This consists, first, in constructing the needle bar or the spindle which carries the vertical needle hollow, and by preference cylindrical, with a slot hole for the insertion of the lever by which the required reciprocatory motion is given to it, and in applying within the said hollow spindle a spiral spring to press upon the lever, and thereby produce an elastic connection, and prevent undue wear by the action thereof. Second, in constructing the bushes or bearing for the said needle bar with a longitudinal slit, so that by a set screw applied externally, the said bush may be contracted, and thereby compensate for wear of the parts working in contact. Third, in the employment of a boss cam for working the feed motion, whether such motion be above or under the material to be sewn, and in the application to the side of said cam a stud with friction roller (by preference of steel) to operate a lever for lifting or working the foot or holder.—Patent completed.

3970 C. MONESTIER and J. BANG, Paris. *Impermeable paper*. Dated December 30, 1868.

This consists, first, in manufacturing imitation collars, cuffs, shirt fronts, petticoats, curtains, and other similar articles, of vegetable parchment, or of paper, or pasteboard, that has partially undergone the process of conversion into vegetable parchment, and which is called impervious paper; and, second, in the manufacture of lace paper and that kind of material usually composed of cotton cloth or

other similar fabric, placed between two layers of paper, pasteboard, or paper pulp. The inventors have also discovered that by treating sized paper by the same process, a slight layer of vegetable parchment is deposited on the surface of the paper, for as the acid cannot penetrate the whole thickness, the effect of the treatment is limited to the surface only. By this process, therefore, they obtain a paper only partially converted into vegetable parchment, a material less stiff, brittle, and transparent, but one which is perfectly waterproof, and can safely be washed in water with soap, alkalies, and other cleansing substances.—Patent abandoned.

3971 G. DAVIES, Manchester. *Separating ores.* Dated December 30, 1868.

This relates to a patent, dated April 4, 1868, No. 1146. The apparatus now comprises a long horizontal hutch or cistern, constructed of wood, bound with iron straps, and formed with a semi-cylindrical bottom. This hutch is divided into four jigging compartments by transverse ends and partitions, and there is also a similarly separated end compartment to receive what passes over the last jigging compartment. A vertical partition extends along the upper parts of the compartment, and on one side thereof there are a set of plungers or pistons to produce the jigging motion of the water, whilst a series of sieves are placed on the other side. On the tops of the partitions, there are fixed a number of standards to carry a longitudinal revolving shaft, provided with fast and loose pulleys for a driving belt, and with eccentrics, which, by means of connecting rods, actuate the plungers. The eccentrics are adjustable on their shaft, so that the stroke of each plunger may be adjusted separately to suit the materials it acts upon.—Patent completed.

3972 P. and R. GORNELL, Blackburn. *Long collars.* Dated December 30, 1868.

This consists in constructing such collars with a bush or ring of brass or other metal at the upper end of such collars, so that, when worn, the bush or ring may be removed and replaced by a new one, instead of having to replace the whole long collar by a new one, as heretofore.—Patent completed.

3973 H. H. BIGG, Wimpole-street. *Artificial legs.* Dated December 30, 1868.

The distinguishing features of this invention are, first, the construction of the ankle joint, and the mode of connecting the foot to the lower part of the leg. This improved mode of constructing the ankle joint admits both of antero-posterior and lateral or horizontal motion; second, the peculiar means of constructing, attaching, and moving the knee joints.—Patent abandoned.

3974 E. J. NONALHIER, Paris. *Ventilating.* Dated December 30, 1868.

This consists of a tube which is surrounded or surmounted by another tube extending round the whole or a portion of the length of the first tube, and provided with a number of vanes, deflectors, or curved or other plates, which, together with radial or other partitions or plates, form air ducts or passages into and through which air is drawn, and whence it passes away round the top or end of the inner tube. The parts may be fixed so that the apparatus may be conveniently used in all requisite aspects, positions, or places. To prevent counter currents, a spherical or otherwise shaped cowl or a dome-shaped cap may be pivoted or hung at the top of the outer tube, so as to take the required positions or inclinations for this purpose.—Patent completed.

3975 J. GEDGE, Kent. *Gas apparatus.* Dated December 30, 1868.

The inventor proposes to construct the gallery or support for the glass with jointed in lieu of rigid arms, as hitherto practised, that is to say, he makes the three or more arms which radiate from the ring movable simultaneously, in such a manner as to permit the glass to pass upwards on the pendent. This is done by jointing the arms either at their junction with the ring or in their centres, such joints being so formed as not to permit the outer portion of the arm to pass downwards lower than a horizontal position, and the globe or glass will be passed on to the pendent from below the pressure of its lower portion against the arms of the gallery will cause them to rise and assume an angular or even a vertical position, thereby permitting the glass to pass up the pendent shaft until its rim shall have passed above the ends of the arms, which will then fall into a horizontal position and form the gallery or support. The glass is then secured thereon at its rim in the ordinary manner; one or more jets may be used, the nipples being fastened on small elbow-shaped burners, projecting from the pendent, and the effect of heat or smoke on this pendent or shaft may be obviated by the use of one or more small reflecting plates, flat, curved, or of any suitable shape, fitted on to the said shaft a little above the burner or burners.—Patent abandoned.

3977 C. DE BERGUE, Strand. *Tramways.* Dated December 31, 1868.

In these tramways the sleepers are in cross section, and of a solid construction, presenting externally a T shape or H shape, or channelled or recessed shape, or corrugated shape, or a hollow construction, presenting externally a circular shape or elliptical shape, or D shape, or wedge shape, or triangular shape, or square shape, or a rectangular shape, or a shape in accordance with any geometrical regular or irregular figure, or whether solid or hollow, or a shape approaching any of those mentioned. The list also includes half or part sleepers of any approved form, that is to say, divided as to their length, but intended to be used in pairs or partsfastened together at their adjoining ends to form combination sleepers, so that although each rail may bear almost entirely on one such half or part, yet a partial support as to inclination or canting may be received from the other such half or part. The list also includes sleepers generally in accordance with any of the foregoing definitions, but having the ends varied or adapted to constitute a chair or seating for rail sometimes constructed with ribs or narrow bearing places in pairs at each position of support, and sometimes finished with provision for holding rails; and, lastly, it includes any combination of the said constructions and shapes.—Patent completed.

3978 W. E. GEDGE, Wellington-street. *Sweetmeats.* (A communication). Dated December 31, 1868.

The ingredients combined in this novel sweetmeat or comfit, and their approximate proportions, are, sugar, 7oz.; marmalade of any kind, 1oz. 12 drachms; rum or other spirit, 11 drachms; and extract of meat 11 drachms.—Patent abandoned.

3979 W. R. LAKE, Southampton-buildings. *Spinning machines.* (A communication.) Dated December 31, 1868.

This consists, first, in a flyer, so arranged as to be suspended directly from a hollow tube, the latter being provided with a pulley or wheel or equivalent device, by which the flyer and tube are caused to revolve, the yarn to be twisted, whether single or double, passing through the hollow tube, and the flyer and tube with its whirl being entirely independent of the bobbin spindle. Second, in the combination of the bobbin with a swinging adjustable rail, in such manner, that when the said rail is let down for "doffing" the bobbins, it can be swung out from under the flyer, and thereby facilitate and expedite the operation of doffing.—Patent completed.

3980 W. R. LAKE, Southampton-buildings. *Separating fibres.* (A communication). Dated December 31, 1868.

This relates to a machine for picking hair from hair ropes. It consists of a revolving tube through which the rope passes, and of an arm projecting from one end of the tube, and carrying a spool or roller, the axis of which is at about right angles with that of the tube. The rope is wound once around the spool which revolves around the axis of the tube, and thus the twist is taken out of the rope as it is being drawn forward. That end of the rope which is not being acted upon is attached to a swivel hook which is secured to a sliding block. The latter is guided on a wire or other rail, so as to move towards the machine as the rope becomes shorter. Second, in the construction of the aforesaid swivel hook or clamp. The same is made of two spring plates, the ends of which are bent towards each other, and are pointed so as to grasp the rope between them. A sleeve sliding on the plate presses them together, so as to clamp the rope when the sleeve is on the front end of the plates. When the rope becomes so short that it cannot be held by the hook, the latter is drawn against the tube, and thereby the sleeve is pushed back on the plates, so as to release the rope.—Patent completed.

3981 F. A. K. W. VON OPPEN, Pall Mall. *Firearms.* (A communication). Dated December 31, 1868.

This relates to pistols or rifles which have a revolving chambered breech or cylinder capable of being loaded from the front, the principal object of the invention being to produce a device by which a revolver adapted for the use of loose ammunition can at a small cost be so changed that cartridges having primed metallic shells may be used. It has for a further object to provide a revolver with means for the ejection at will of the cartridges or empty cases from the chambers of the rotating breech, and also to provide against accidental discharge of the weapon. It has for a further object the reloading of the empty cartridge shells, by an attachment which can be placed upon and used with the arm, and also the provision of a suitable cartridge for the said arm.—Patent completed.

3982 A. BARCLAY, Kilmarnock. *Air pumps.* Dated December 31, 1868.

This relates to an arrangement or construction of air pumps, whereby a vacuum may be formed in a receiver or other vessel of any assigned degree of completeness or perfection, which consists as follows:—The lower part of the air pump, barrel, or cylinder is connected by a pipe or passage to an upright hollow column, the column terminating at the upper end in a cup or receptacle, the latter being provided at its junction with the hollow column with a valve. At a distance below the cup or receptacle hereinbefore mentioned, a branch proceeds from the hollow column, by which the hollow column communicates to the receiver, a suitable valve and valve seat being placed between the hollow column and the receiver. In the cup or receptacle at the head of the hollow column, an overflow is formed, and situated immediately below the overflow is a reservoir communicating with the barrel or cylinder of the air pump, the communication, however, being closed by valves except at the time, as hereinafter set forth, when it is requisite that the communication should be open. The required quantity of mercury is placed in the barrel or cylinder, the communicating pipe or passage, the upright hollow column, and the branch leading to the receiver as well as in the reservoir in connection with the barrel or cylinder.—Patent completed.

3983 B. SAMUELSON, Banbury. *Iron and steel.* Dated December 31, 1868.

The objects are, first, to produce a superior quality of wrought iron from pig or cast iron containing phosphorus, silicon, sulphur, or other impurities. Second, to prevent sand, slag, and other extraneous substances from running into the moulds when iron or steel is melted in a reverberating furnace and run into moulds. According to the first part of this invention, the inventor proposes to purify pig or cast iron in a reverberatory furnace, having, by preference, what is ordinarily known as a cinder bottom, and being by preference suspended for the convenience of discharging its contents. This purification may be effected by such appropriate re-agents as will dispense with the necessity of using a blast, and the purification is carried on until the iron approximates as to its per centage of silicon to that contained in ordinary refined iron, during which operation a large proportion of the other impurities will also have been removed. The purified iron is then tapped out, and subsequently puddled in a puddling furnace. By this method, it is easy to produce from cast iron containing one and a-half per cent. of phosphorus wrought iron, in which the ultimate per centage of phosphorus shall not exceed 1-10th to 2-10ths per cent. The metal when purified or refined is run into moulds, and the ingots or blocks are, whilst still hot, removed from the moulds and placed in a furnace, by preference situated in close proximity to the puddling furnace, where they are removed in a heated state for the purpose of being puddled.—Patent completed.

3984 D. SPILL, Hackney. *Compounds containing xyloidine.* Dated December 31, 1868.

This relates to the production of materials or compounds containing xyloidine, and consists in the admixture of xyloidine (or that product which results from the action of a mixture of sulphuric and nitric acids upon ligneous or vegetable fibre) with animal, fish, vegetable or mineral oils oxidized or otherwise, such for example, as vegetable or mineral tar, lard, oil, cod liver oil, camphor oil or liquid camphor, linseed oil, or heavy coal oils, or with mixtures of the same together with the admixtures of other ingredients, such as paraffine, camphor, resins, fat, wax, india-rubber, gutta-percha, or Balata gum, or mixtures of the same, so as to produce a material or materials which may be employed either alone or in conjunction with pigments or other inert bodies, for the production of a compound, which may be applied for useful purposes in the arts, such for example, as for moulding into forms such as dishes, bowls, tubing, covering telegraph wire, or for rolling into sheets, or otherwise for spreading either upon or between fabrics or otherwise, or for the coating, or for the preservation of metals, wood, and other bodies.—Patent completed.

3985 S. M. WELLS, Barnsbury. *Wrenches.* (A communication). Dated December 31, 1868.

This consists, first, in an adjustable S wrench, composed of two parts morticed and tenoned together, in the manner hereinafter described, the mortice being formed in the exterior, and the tenon in the interior jaw of each part. Second, in combining with the two morticed and tenoned parts of the S wrench, a right and left hand screw and thumbpiece to operate it, thereby contracting or extending the jaws much more speedily than when a single screw is employed. Third, in the construction and combination of the two parts composing the S wrench, each being provided with a tenon and mortice, arranged on opposite ends, so that the plane of movement of the two parts shall be in the direction of the length of the wrench, and at right angles or transversely to the jaws. Fourth, in the combination in an adjustable S wrench of scales upon the shank with the right and left hand screw and thumb piece, so that the wrench may serve the purpose of callipers for measuring iron or nuts.—Patent completed.

3986 H. E. NEWTON, Chancery-lane. *Washing machines.* (A communication). Dated December 31, 1868.

This consists chiefly in the use of a perforated hollow cylinder, inside which is formed a cage consisting of horizontal rods or bars. A door is formed in the perforated cylinder and cage, so that the articles to be washed may be placed in the cage, which, with the whole cylinder, is mounted in a suds box. An oscillating motion is imparted to the cylinder, so that the articles are constantly moved or stirred about in the cage and exposed to the action of the hot water and steam.—Patent completed.

3987 W. E. NEWTON, Chancery-lane. *Firearms.* (A communication). Dated December 31, 1868.

This consists in constructing a metal-cased cartridge with a hollow flange around the rear end of its metal case. The hollow flange projects backwards parallel, or nearly so, with the length of the cartridge, and has an external circumference no greater than the rest of the case. This flange contains the fulminate priming, which may be fired by the hammer of the firearm striking through a suitable opening provided in the rear of each chamber of the cylinder.—Patent completed.

3988 R. GRIFFITHS, Flint. *Screw propellers.* Dated December 31, 1868.

This relates to improvements by means of which the blades of screw propellers may be carried to assume such a position as will offer the least possible resistance to the passage of a vessel through the water at those times when the propeller is not employed in moving the vessel. The inventor forms the blades of the screw propeller separately from the boss, and with shanks, which are inserted in suitable sockets formed in the central boss, so that the blades can be turned from an angle or "pitch" suitable for propelling the vessel to such an angle, in relation to the axis of the screw shaft, as will present the least resistance to the passage of the vessel through the water when the propeller is stationary. Into the shank of each blade the inventor inserts a key, which serves to connect the blade to the boss. These keys are secured in the shanks of the blades, and project through apertures formed in the sockets in the boss for the reception of the shanks of the blades, such apertures being so formed as to allow of the partial relation of the shanks of the propelling blades within the sockets, one end of such aperture stopping the keys and blades at the "projecting pitch" and the other end at the "sailing pitch." In addition to the keys above named, he forms the collar of the shank of each blade with an angular edge, and secures rings upon the boss after the shank of the blade is inserted, so as to hold the angular edges upon the collars of the shanks, and so assist in securing them to the boss.—Patent completed.

3989 T. GIBSON, Newcastle-on-Tyne. *Buffers.* Dated December 31, 1868.

A movable hollow piston, to which the buffer head is connected, is accurately fitted within an iron shell or cylinder, fixed to the carriage or waggon or other situation on railways, and a convex steel disc is inserted in the piston between a packing plate and collar, and suitably packed. Another convex steel disc is inserted in the shell or cylinder, such disc being set on a turned shoulder and packed and being held in its required position by the ordinary backing plate to which the flange of the shell or cylinder is fixed.—Patent completed.

3990 J. SEELIG, Bunhill-row. *Ventilating hats.* Dated December 31, 1868.

The inventor makes the body of the hat of muslin, calico, or other fabric, covered with merino, silk, or other ordinary material used for covering hats, and he forms therein one or more ventilating holes or orifices at the back and front in such a position as to be covered by the hat band. He also forms in the body of the hat other ventilating holes at a part or parts above the hat band. The ventilating holes are preferably in many cases protected by eyelets. He forms an improved tip for the hat of net buckram, galvanized wire, or other open mesh or large gauge fabric, which is rendered sunproof and waterproof (without interfering with the ventilation through the same) in the usual mode in which such fabrics are treated for the purpose, or the tip may be made of a reticulated fabric, which he calls air cloth, and which consists of wool and cotton threads woven, of about the same gauge, mesh, or shed, or net or buckram, each thread being compound, that is to say, consisting of a number of component threads, each of which is first separately twisted, and then the whole are twisted together. The air cloth or the tip made of air cloth is made waterproof and sunproof, as above described. The tip is covered with merino satin, or other covering material ordinarily used in the covering of hats. There are no holes formed in the tip, as the net, buckram, air cloth, or wire permits the passage of currents of air through the whole tip.—Patent completed.

3991 C. SHALES, Westbourne Grove. *Shuttles.* Dated December 31, 1868.

This relates to improvements in the shuttles used for tatting. The inventor makes the shuttle solid instead of forming it of two blades having a space between them, as above referred to, and at the centre of the shuttle he forms a slot or opening for receiving an ordinary spool or reel

containing thread. This spool he places on an axis or pin fixed to one side of the shuttle in a transverse position across the centre of the slot, on which pin the spool is free to revolve. One side of the shuttle, by which the spool is enclosed when in position on its axis, is made movable, either on a hinge or in any other way, or it may be detachable, to permit of the introduction of the spool, the side of the shuttle being secured in the closed position by entering a dovetail, groove or otherwise. This latter arrangement is also applicable to existing shuttles.—Patent abandoned.

1 J. HEAP, Lancaster. *Gearing.* Dated January 1, 1869.

This consists in a modification of a perpetual wedge machine. To make this apparatus applicable to the present purpose, the inventor arranges, modifies, and combines it with a wheel, drum, or speed pulley running loose on the shaft spindle or axis, to which the slow motion is to be communicated. The first modification and arrangement consists in the application of two internal toothed wheels of the same diameter or thereabouts, one of which has one, two, or more teeth more than the other. These two wheels are placed on the shaft spindle or axis, to which the slow motion is to be communicated, and with which they are concentric. One of the wheels is keyed on to the shaft spindle or axis, and the other is loose and is prevented from turning round by being attached to the framework of the apparatus. The wheel, drum, or speed pulley runs loose on the shaft, spindle, or axis, and has on its boss an eccentric which carries an external toothed wheel. This external toothed wheel gears into both the internal toothed wheels, and is, consequently, about as broad on the tooth as both of them together. The two internal toothed wheels, the external toothed wheel, and eccentric are so modified, constructed, and arranged as to be enclosed in the interior of the wheel drum or speed pulley, which is made hollow for that purpose, and which receives motion from the first mover.—Patent abandoned.

2 T. SINGLETON, Lancaster. *Yarn apparatus.* Dated January 1, 1869.

This consists, first, in certain improvements in sizeing machines and operations connected with them, and also in the management of the size. In the sizeing machines having cone drums, the inventor drives the drums with one or more india-rubber straps coupled together in one or more places, by which means the strap or straps can better adapt themselves to the angle of the cones. The india-rubber band is cut in the middle into two straps, but leaving one or more parts uncut to form the coupling. In all sizeing machines he attaches to each end of the first dividing rod a weight or spring for the purpose of drawing the rod forwards towards the point of the separation of the yarn, so that when there is a hard and matted place in the yarn the rod can recede and prevent breakage.—Patent abandoned.

3 S. LYONS, Finsbury. *Designs on cloth.* Dated January 1, 1869.

The inventor forms the selvages thereof into ornamental borders by weaving or printing the same with emblematical or other devices or designs (in imitation of the various games or sports), upon tinted or coloured grounds, in such manner that the fabrics when made up into trousers shall represent upon the dark coloured stripes or borders a device corresponding to the game or sport for which the trousers aforesaid are to be worn; for example, as a device for cricketing, it is preferred to employ small vignettes disposed throughout the entire length of the border (pourtraying a cricketer at the stumps with bat and ball) in relievo upon a dark ground obtaining in like manner corresponding results, with varied designs and shades of colour, emblematical of boating, yachting, racing, hunting, sporting, fishing, velocipeding, football, or similar sports or games.—Patent abandoned.

4 W. M. WILLIAMS, Sheffield. *Puddling furnaces.* Dated January 1, 1869.

This consists in fettling or lining the beds and sides of puddling furnaces with crude or prepared oxide of manganese or manganese ore, either as the chief ingredient of the fettling or as an addition to the oxide of iron or other material which is or may be employed for fettling or lining the said furnaces. In using crude or native oxide of manganese, or manganese ore without admixture with other solid, the inventor selects an ore which, when pulverized and moistened, will form a plastic or pasty mass, and which, when heated, will harden and adhere firmly to the sides and bottom of the puddling furnace. For this purpose the cheap oxides containing a considerable proportion of iron are best suited, provided they do not also contain other impurities, such as sulphur and phosphorus, which would injure the iron in the furnace.—Patent completed.

5 G. SMITH, Strand. *Clipping horses.* Dated January 1 1869.

This consists of a band saw or a band knife arranged or fixed for use somewhat differently, so as to be applicable to the various uses indicated below. For the purpose of clipping horses and sheep the inventor forms a small case of iron, and by a barrel spring turns a centre spindle, on which is also fixed a pinion wheel, which drives two pinions right and left of the first pinion. On the spindles of these outside pinions the inventor fixes pulleys for a band knife, which is to pass between a double comb; the double comb is roughed or barbed on the inside so as to detain the hair or wool; when the knife is brought forward, pressure is given to the hair or wool, and is thus cut. The knife band will be brass, copper, or leather with steel face or cutting part.—Patent completed.

6 T. GREEN, Leeds. *Boilers.* Dated January 1, 1869.

In place of employing inclined tubes passing across the firebox, the inventor places within the firebox of vertical boilers having internal fireboxes, as above described, a tube or tubes bent into coils rising one above the other from the bottom to the top, or any less intermediate space of the firebox, the upper and lower ends of the coil being connected to the annular water space of the boiler at or near its upper and lower ends respectively. By this means a greater amount of heating surface is obtained, with fewer joints to be made, and a more perfect circulation of the water in the boiler is obtained.—Patent completed.

7 T. GREEN, W. BURROWS, and R. TURNER, Leeds. *Casks.* Dated January 1, 1869.

The inventors employ a bush composed of two tubes, one of which fits within the other. Each tube has at one end a flange formed around it; the flange of one tube is to rest against the inside face of the stave, whilst the flange of the other is to rest against the outside face of the stave. The outer tube is made of a conical form, and to fit within the hole which is to be bushed. It may be of malleable cast iron or other metal sufficiently strong and tough; the inner tube or liner is made with parallel sides, and to fit within the smaller end of the conical tube; this inner tube or liner is made of a metal which will allow of its being expanded to fit within the conical outer tube.—Patent completed.

8 B. G. GEORGE, Hatton Garden. *Almanacks, &c.* Dated January 1, 1869.

The inventor introduces the use of flock, especially such as that employed by wall paper manufacturers for enriching the appearance of the show card and giving it a novel aspect. For this purpose he prints upon paper in or with adhesive cement or varnish the pattern or design of letters or ornaments or the device which he desires to produce, and he then applies flock thereto, and these operations he repeats as often as desired until he produces a highly raised surface in flock. Or, reversing this process, the inventor raises the ground with repeated coatings of flock, and thus produces a sunken device; or he first prints a design in water colours, after the manner of wall paper printers, or in the ordinary method of oil printing, and to certain parts of the design he applies, as above described, as many superimposed layers of flock as may be required. The combination of the two methods greatly enhances the beauty of the work.—Patent completed.

9 F. PERRY, Fenchurch-street. *Preserving substances.* (A communication). Dated January 1, 1869.

The inventor employs a solution hereinafter distinguished as solution No. 1, which is a solution of bisulphite of lime in water, with the specific gravity of 1·020 to 1·080. Under some circumstances it will be found convenient to substitute a solution of bisulphite of lime and magnesia, which compound may be formed by saturating acid sulphite or bisulphite of lime with carbonate of magnesia, or by saturating acid sulphite or bisulphite of magnesia with carbonate of lime, or the admixture of solutions of sulphite or bisulphite of lime with sulphite or bisulphite of magnesia in combining proportions. The specific gravity of the solution may be between 1·020 and 1·080, or even greater when required for the purpose of bringing up the strength of solutions which have been weakened by repeated use. The inventor sometimes forms another solution by dissolving the ordinary gelatine in boiling water, using from 1 part to 2 parts of gelatine in 10 parts of water, and adding 10 parts of solution of either of the solutions above described. In determining the proportion of gelatine to be used, he increases such proportion in the inverse ratio to the decrease of the temperature of the place at which the solution is to be applied, using a larger proportion of gelatine when the temperature is low and a smaller proportion of gelatine when the temperature is high.—Patent completed.

10 M. HENRY, Fleet-street. *Combing fibres.* (A communication). Dated January 1, 1869.

In this machine a variable number of rollers are used. Supposing there be two pairs of rollers, each pair consisting of an upper and under roller, the under rollers being driven by a steam engine or other prime mover, and the upper rollers acting as pressure rollers working by friction, and suppose that between two pairs of rollers there be two combs passing through a sliver lap or hank of fibrous material passed between the rollers. Now, if one pair of rollers revolves while the other pair remains stationary, the revolving pair will seize the fibrous materials and readily draw them through the teeth of the combs, provided that when the rollers begin to move, the ends of the filaments shall not have reached the point of contact between the cylinders, as these would otherwise have held them, or if the other roller were not pressed down at that moment upon the corresponding roller, but just rested thereon so as to allow the filaments beyond the point of contact to pass freely towards (when drawn by) the first pair of rollers. If these rollers continue working until the ends of the filaments are drawn quite from between them, all the filaments which that pair had laid hold of or drawn out will remain between the pairs of rollers.—Patent completed.

11 J. H. JOHNSON, Lincoln's Inn-fields. *Velocipedes.* (A communication). Dated January 2, 1869.

The front and rear wheels are held together by a curved central bar, the front end of which forms a socket for the reception of the vertical forked spindle carrying the steering wheel, whilst the hinder extremity is forked and connected freely with the main axle upon which the two driving wheels are made fast. Near to the upper end of the vertical forked spindle is jointed a horizontal propelling lever provided at its rear end with swivel cross handles for imparting a reciprocating motion thereto in a vertical direction, whilst a counter weight is attached to the front overhanging extremity of the propelling lever to assist in lifting it after each depressing or downward stroke. The swivel cross handles are coupled by rods to corresponding cross arms fast on the vertical spindle, so that by turning the handles more or less the steering wheel will be also turned to a greater or less angle, thereby altering the course of the vehicle, and enabling it to be steered with facility. A connecting rod descends from the propelling lever, and is jointed to a pawl lever working loose on a horizontal shaft, such shaft having mounted loosely thereon two ratchet wheels, the teeth of which are in reverse directions. To one of these ratchet wheels there is secured a chain wheel which drives by means of a pitch chain or chain pinion fast on the driving axle.—Patent abandoned.

12 S. SMITHSON, G. SENIOR, and J. INMAN, York. *Taps and valves.* Dated January 2, 1869.

This relates to taps or valves for regulating the discharge of fluids, and consists in constructing the valve either so as to have a surface of cork fixed to it, or to press upon a surface of cork fixed in the seating, and to be capable of moving to or from the seating without turning on its axis, being attached to the spindle by a screw thread, and the spindle is formed to fit a conical gland so as to avoid packing. By turning the spindle in one direction the valve will be removed from its seating to open the passage, and by turning it in the other direction it will be pressed upon it, and thereby close the passage.—Patent abandoned.

13 A. BATCHELOR, Brockham. *Bricks, &c.* Dated January 2, 1869.

This consists in so constructing an ordinary kiln of circular or other form with fireplaces, that the heated air and products of combustion may be made to pass first upwards around the bricks or other ware stacked in the kiln, and then being made to descend through and amongst the bricks may either be allowed to pass direct into the chimney (which may be constructed in the centre thereof or at a distance from it, the passage leading thereto being at or near the bottom of the kiln), or they may be conveyed by suitable flues into one or more other kilns of similar structure, which, as hereinafter explained, may be made to work in conjuction with it.—Patent completed.

14 W. S. RAWBONE, Birmingham. *Firearms.* Dated January 2, 1869.

This consists of a strong tubular plug of a size and figure proper to accurately fill up the cartridge chamber of the barrel. The base or rear end of the plug is provided with a rim or flange similar to the rim or flange of a breech-loading cartridge. The rim or flange of the plug, when the plug is placed in the barrel, occupies the depression at the mouth of the barrel in the same way as the rim or flange of the breech-loading cartridge.—Patent abandoned.

15 A. CARTER, Birmingham, and C. R. E. GRUBB, Dalston. *Candlesticks.* Dated January 2, 1869.

This consists in providing candlesticks with a receptacle for containing a supply of matches, so that should the candle be extinguished the means of reigniting it may be always at hand. In making flat candlesticks, for instance, the inventors provide a suitable box or receptacle for matches at the bottom of the central stem or holster, the latter being mounted upon it, and the box being fixed at the centre of the tray forming the base of the candlestick. This box, which may be of any convenient shape, they prefer to provide with a hinged lid at one or both ends, while the lid may be inclined, and also carry the friction surface. By means of this improvement, the danger of dropping matches when carried loosely on the tray, as heretofore, is obviated, whilst the means of igniting the candle are always at hand; other kinds of candlesticks may also be similarly provided with a match receptacle placed in the foot or pedestal.—Patent completed.

16 J. G. TONGUE, Southampton-buildings. *Bookbinding* (A communication). Dated January 2, 1869.

This relates to a previous patent, dated January 10, 1868 (No. 98). Two adjustable tables are provided, one to hold the unstitched and the other the stitched parts of the volume or volumes, and it is preferred to cause the one table to rise as the other falls, by means of rack and pinion or other suitable mechanical contrivances, so that as the parts or folds are transferred from one to the other, the surface of the paper upon the tables will be maintained at the same relative height. The saw nicks or binding cuts in the folds are placed over the needles or instruments where the thread is to be laid, part of the fold resting upon the stitched work or table, and the other part, according to this invention, upon an auxiliary table, which is called the assistant folder. There are also fingers or instruments provided termed "lifters and folders," which are below the fold when laid over the needles, and after the thread is laid by the thread carrier. The "lifters and folders" are so actuated as to first raise the sheet up, the needles at the same time moving from between them, the "assistant folder" also at the same time turning over the fold, and at the right moment the "lifters and folders" move forward again between the needles and complete the turning over of the fold, the "assistant folder" at each movement pressing down the folded parts and the table upon which they rest sufficiently to make room for the next fold to be laid over the needles. At the same time that the fold is turned over as above described, guides or thread carriers are caused by suitable mechanism to pass a thread at the back of one or both of the end needles, and these guides are so actuated as to pass the thread first from right to left and then from left to right at the back of the needles, the guides being mounted upon a sliding rod and actuated by a pin and a shifting cam surface.—Patent completed.

17 M. WOLFSKY, Pilgrim-street. *Locks, &c.* Dated January 4, 1869.

This consists in a lock or fastening in which there are two plates of metal and a catch or clip which is fixed to the outer plate, and works over a plate on a centre having a movement to the right and left. There is a small steel spring under clip, and a plate is placed over the other plates, the circular opening in the same being immediately over the clip. The three plates being thus arranged, the plate being moved a little on one side, the flap is folded down in the usual way, the circular opening in upper, plate closing over the metal pin, the catch or clip on the plate is moved slightly, so as to be caught by the head of the pin, and thus becomes fastened. To open the lock, the outer plate has merely to be moved to the right or left and the catch is released.—Patent abandoned.

18 H. A. BONNEVILLE, Sackville-street. *Steel.* (A communication). Dated January 4, 1869.

This consists, first, in introducing fuel or fluxes, either in a gaseous, liquid, or solid form, into the molten metal in a converter, by suction (in contradistinction to the process heretofore known where fuel has been introduced by force) in such a manner that the quantity of fuel as well as the quantity of air introduced into the molten metal can be regulated, and the requisite amount of heat for refining the iron or for converting it into steel can be produced. Second, in subjecting the fused metal in the converter to a forced current of air in combination with the current produced by suction, or by a vacuum apparatus, in such a manner that the advantages of the vacuum process are combined with those of the forced air process, and that the action of the air on the fused metal can be regulated with greater facility and nicety than it can if either the vacuum process or the forced air process is used independent of the other.—Patent completed.

19 W. A. BIDDELL, Birmingham. *Chandeliers, &c.* Dated January 4, 1869.

This relates, in the first place, to a new mode of forming or ornamenting chandeliers, lamps, lustres, and other articles. This is effected by attaching, either by fusion or by other suitable means, various ornamental devices made of pressed glass, either plain, coloured, or inlaid. The inventors produce their ornamental pressed glass suitable for this purpose by colouring or inlaying the interior of the glass after being taken from the moulds.—Patent abandoned.

20 P. J. PEEL, Leeds. *Valves.* Dated January 4, 1869.

The sliding portion of these improved valves are divided longitudinally into two parts, which, when the valve is

closed, are pressed apart from one another and against their seats; when the valve is to be opened the two parts are drawn towards one another and away from their seats, and the slides can then very readily and with very little friction be drawn up into the chamber. To thus force the two parts parts away from one another when the valve is closed, a wedge is employed which is formed with a stem passing up through a stuffing box in the top of the chamber; the stem of the wedge has a screw thread cut upon it, either to work into corresponding portions of threads cut in the two halves of the slides, or the screw of the stem may work into a thread cut around the sides of a hole formed through the wedge itself; in either case, the wedge may be forced down between the parts of the slides by turning the stem.—Patent completed.

21 J. M'KENNY, Dublin. *Horses' shoes.* Dated January 4, 1869.

This consists in the application of an artificial additional frog or solepiece of india-rubber, leather, or other suitable material, to the shoes or feet of horses or other draught animals, the solepiece bearing on the ground when in action for the purpose of bringing the natural frog into action, instead of the wall of the hoof sustaining the whole of the pressure, as is the case in the ordinary mode of shoeing, and which is the reverse of the natural arrangement of the foot. This solepiece also serves as a protection to the foot. The inventor attaches the solepiece to the foot in any suitable manner, such as by means of pins projecting from the solepiece taking into corresponding holes in the inside of the shoe, so as to allow of the ready application and renewal of the solepiece, or it may be otherwise secured in position.—Patent completed.

22 J. MAJOR, Haddington Trigg, and W. WRIGHT, Middlesex. *White lead.* Dated January 4, 1869.

This consists, essentially, in the employment of a chamber capable of being opened and closed as desired, composed of slate, glass, marble, or of other materials not acted upon by either of the hereinafter mentioned acids, and of any convenient dimensions according to the production desired. Within this chamber are suspended or deposited a number or series of sheets of lead, which are by preference rolled or otherwise shaped or perforated, with a view to expose as large a surface as possible to the action of the vapours and the atmospheric acid hereinafter referred to, which are introduced into the said closed chamber after the lead has been placed therein.—Patent abandoned.

23 H. A. BONNEVILLE, Sackville-street. *Plating.* (A communication). Dated January 5, 1869.

This relates to a new and improved process for coating all sorts of articles with gold, silver, platinum, zinc, and all other such metals or mixtures of metals as may be beaten into sheets between the gold beaters' skin in the usual way. Like coatings may be effected upon silken, woollen, cotton, flaxen, hempen, or other thread, and upon the textile materials made of such thread, without losing anything of their suppleness, and at the same time imparting to them a metallic brilliancy. Preparation for the gold coating:—Ochre or oxide of iron not calcinated, and perfectly purified by a washing, is mixed with painters' varnish made of linseed oil boiled with litharge or oxide of lead. This varnish must be perfectly pure and clear. The mixture is crushed in a mill or on a marble slab, by adding from time to time some good oil of turpentine, called American oil of turpentine. To this mixture is added, for every 500 grammes of matter or substance, 150 grammes of painters' varnish of the finest quality, 30 grammes of old mordant varnish, slow in drying, like that used in a fresh state to make typographical ink, and 45 grammes of oil called East Indian oil, and of cobalt resin diluted in painters' varnish. The whole is then intimately mixed by crushing on a marble slab or in a mill. The mixture is next subjected, in a glazed gritstone vase, to the action of a moderate heat, until it attains such a consistency as to form threads between the mass and the end of a stick steeped into it on being withdrawn. The mixture is then allowed to cool, and when required for use it is diluted with pure and rectified oil of turpentine in such a quantity as to avoid soaking and drenching the articles or objects to be ornamented.—Patent completed.

24 L. HANNART, Clerkenwell. *Types, &c.* Dated January 5, 1869.

This consists in making a long pattern or trough in wood or other suitable material or substance with several separate letters thereon or therein, placed at suitable distances asunder, for the purpose hereinafter stated. The pattern, when cast from sand, the inventor places on a planing machine, and planes all the sides true and to a gauge. This done, he cuts or divides the casting crosswise by a circular saw or other suitable means, so as to separate the letters, which are then ready to be set up by the printer, each piece being as near as may be of the same size, so that when set up they may present a flush surface.—Patent completed.

25 S. BATEMAN, Paris. *Paddlewheels.* Dated January 5, 1869.

This consists in placing round the wheels for moving vessels and other floating bodies movable paddles consisting of two parts united together, one part placed beyond the axis of oscillation. Relatively to the centre is the paddle properly so called. It carries a joint at its outer end, the second part placed between the axis of oscillation, and the centre of the wheel has also a joint at its inner end. Each paddle is jointed to the following one by a connecting rod passing from the inner joint of one paddle to the outer joint of the other, or by any other suitable means.—Patent completed.

26 W. PROSSER, Lancaster. *Oils, &c.* Dated January 5, 1869.

This consists in the purification, bleaching, and saturation of certain animal and vegetable oils, also of gums and resins, as well as of such liquids as oil of turpentine, spirits of turpentine, and methylated spirits, by means of ozone, whereby much time is saved and greater purity obtained than by the methods at present in use. For this purpose the inventor treats the oils, such as raw or boiled linseed oil, calve's foot oil (otherwise called neat's foot oil), cod liver oil, castor oil, olive oil; also such gums as gum aniline, gum copal, gum caori or Australian gum, amber, and gum sandarach; also methylated spirits, spirits of turpentine, and oil turpentine with ozone.—Patent completed.

27 E. W. and J. VOCE, Salford. *Rotary fans.* Dated January 5, 1869.

This relates to the construction of rotary fans, such as are used for the production of currents of air for ventilation and for various manufacturing purposes, and has for its object the increase of the amount of blast produced. The improvements consist principally in providing the casing or shell which surrounds the fan with two or more vents or discharge openings (in lieu of one only, as commonly employed), and in increasing the diameter of the central or inlet openings in a corresponding degree. In fans as usually constructed with, say, three vanes and only one vent or discharge opening, much air enclosed between each two vanes is carried round more than two-thirds of the interior of the casing uselessly before it is discharged at the vent, whereas by making three vents in the casing the wind raised between each two vanes is discharged immediately, and, consequently, about three times the volume of air may be propelled by a fan of the same diameter. In order to compensate for the rapidity with which the air is discharged, and to prevent "wire drawing," the inventor increases the diameter of the central or inlet openings in a corresponding ratio, so that their united area is somewhat in excess of the united area of the three vents or discharge openings.—Patent completed.

29 J. J. HAYS, King's Cross. *Peat.* Dated January 5, 1869.

This relates to improved machinery or apparatus for getting peat from the bog, to improved machinery for working and drying peat for fuel, and to improved modes of carbonizing peat. The machine employed for digging or getting peat from the bog consists of a drum fixed to a proper framing, and caused to rotate by means of a portable engine, either attached to the machine, though it may be separate therefrom. The drums are formed with inclined cutting segments that pare down the peat in thin strips or layers, which fall into the interior of the drum and are there triturated and thrown out on to endless bands or otherwise by rapidly revolving arms rotating round the axis of the drum but at a greater speed.—Patent completed.

30 J. BALBIRNIE, M.D., Sheffield. *Vapour inhaler.* Dated January 5, 1869.

This consists of a jar or other vessel provided with one or more necks or outlets and inlets, through which water and the medicated material are inserted, which are required to be inhaled in the form of vapour, as well as connecting tubes inside and outside, through which the air and vapours or gases find entrance and exit. The interior tubes may be of glass or any other suitable material, connected on the outside with the india-rubber tube or tubes of any other suitable flexible material. The entrance tube is provided with either a common pair of bellows or a force pump, or with one or more compressible balls, vessels, or reservoirs, which, when worked or compressed, force air through the water contained in the jar or vessel, continuing to a mouthpiece or outlet, whereby the vapour may be inhaled directly, either with or without the contact of the mouth of the patient, or whereby the vapour may be caused to permeate the room of a patient, or surround his couch, chair or bed.—Patent completed.

31 J. H. JOHNSON, Lincoln's Inn-fields. *Sewing machines.* (A communication). Dated January 5, 1869.

A grooved wheel is employed, mounted loosely on the driving shaft, which by the upward motion of the treadle is brought into contact with a friction ring by means of a lever acting upon the same. A second and similarly grooved wheel acts in the same manner upon another friction ring upon the downwards motion of the treadles, the friction ring acting alternately upon a third wheel, which may be termed the driving wheel, situate between the two grooved wheels above referred to, and secured to or made fast on the shaft by a set screw, the parts being held together by means of adjustable collars upon the shaft.—Patent abandoned.

32 A. MASON, Craven-street *Oils.* (A communication). Dated January 5, 1869.

The oil to be distilled is placed in a closed still, and retained under pressure, whilst it is vapourized by means of steam blown into it. A pipe fitted with a throttle valve leads from the top of the still to a condenser, and this valve is kept closed until the desired pressure of steam has been obtained in the still. The valve on the pipe leading to the condenser is then gradually opened, and it and also a valve on the steam pipe is kept so adjusted that whilst the oily vapours and steam pass off the condenser, the desired pressure in the still is kept up by the inflow of steam. A pressure gauge is fitted to the still, so that the pressure in the still may be readily ascertained; it is preferred to employ a pressure of about 90lb. to the square inch, but this may be varied.—Patent abandoned.

33 G. SMITH, Manchester. *Consumption of smoke.* Dated January 5, 1869.

The inventor places at the back of the fireplace an additional bridge, composed of firebrick, or clay, or other suitable material, one end of which bridge rests on the firebars a short distance from their back ends, and its top part and other end project over the ordinary bridge, so as to leave a hollow space or air chamber the whole width of the fireplace communicating with the flue. By this arrangement, a current of cool air is introduced through the spaces between the back ends of the firebars to the hollow space or air chamber, from which it immediately comes in contact with the smoke and gases from the ignited fuel, and causes their instant combustion or conversion into flame.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated July 20, 1869.

2185 R. G. Fisher, Great George-street, Westminster. Improvements in rafters or bearers for roofs and floors.

2186 T. Holt, Rochdale, Lancashire. Improvements in apparatus for supplying and distributing disinfectants to closets and similar purposes.

2187 R. Olivier, Paris, Boulevard de Strasbourg. Certain improvements in the manufacture and construction of velocipedes and other similar vehicles.

2188 F. Fleming, Halifax. Improvements in driving straps or belts.

2189 R. Saunders, Croydon, Surrey. Improvements in buffing railway carriages, and in materials for the same, which is also applicable for springs generally.

2190 J. Rehse, Rupert-street, Middlesex. An improved system for the cure of stammering.

2191 J. E. Holmes, Buckingham-street, Strand. An improved mode of attaching or securing the free ends of wire and other ropes.

2192 W. Rose, The Mount, Halesowen, Worcestershire. An improvement or improvements in bearings for cast-iron rolls and shafts, and other rotating bodies made of cast iron.

2193 D. Trevor, Birmingham. New or improved apparatus for facilitating the production of photographic pictures, as also in the mounts or cases and fittings for the same.

2194 A. Stansfeld, Cornhill Chambers, City. Improvements in apparatus for propelling on land and in water.

2195 S. Hall, Swansea, Glamorganshire. Improvements in apparatus for moulding artificial fuel, applicable also to the moulding of bricks or building blocks.

2196 J. H. Johnson, Lincoln's Inn-fields. Improvements in dyeing and printing.

2197 H. Higgins and T. S. Whitworth, Salford, Lancashire. Improvements in machinery or apparatus for preparing, spinning, and doubling cotton, and other fibrous materials.

2198 G. Finnegan, Dublin. Improvements in machinery for sawing wood and stone, part of which is applicable also to other machines in which cranks are used.

2199 J. Ellison, Lisburn, Antrim. Improvements in the manufacture of rope, cord, and twine, and in the machinery therefor.

2200 H. B. Clark, Hyde Hall, Buntingford, Herts. Improvements in horse rakes.

Dated July 21, 1869.

2201 J. W. Larmuth, Pendleton, Lancashire. Improvements in means for connecting together the ends of the hoops or bands employed in the packing of cotton or other substance or material.

2202 J. Duke, Dover, Kent. Improvements in the construction of ships.

2203 J. Ogden, Manchester. A combined tap and filter for water and other liquids.

2204 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in marline spikes.

2205 W. Brookes, Chancery-lane. A new or improved mode of spinning carded wool on small cops ready for weaving.

2206 G. Follett, Bird-in-Bush-road, Peckham, Surrey. An improved waterproof facing for brick buildings.

2207 G. H. Ellis, Gracechurch-street, City. Improvements in rotary engines.

2208 A. H. Brandon, Rue Gaillon, Paris. Improvements in springs applicable to railroad or street cars and other purposes.

2209 G. Allibon, Rosherville Iron Works, Northfleet, Kent, and A. Manbre, Baker-street, Middlesex. Improvements in steam boilers.

2210 J. Boyd, Glasgow. Improvements in machinery for winding yarn or thread.

2211 A. C. Kirk, Glasgow. Improvements in apparatus for abstracting heat.

2212 J. H. Johnson, Lincoln's Inn-fields. Improvements in obtaining extract from hops.

2213 H. E. Newton, Chancery-lane. An improved brad driver.

2214 M. Tildesley, Willenhall, Staffordshire. Improvements in ties, clips, or fastenings for connecting the bands employed in securing bales of cotton, wool, and other products capable of being packed in a similar manner.

2215 A. M. Clark, Chancery-lane. Improvements in carding engines.

2216 F. M. Mole, Birmingham. Improvements in the manufacture of matchets and cutlasses.

2217 H. Knight, Ryde, Isle of Wight, Southampton. Improvements in instruments or apparatus for clipping horses and other animals.

2218 G. T. Abbey, Birmingham. Improvements in breech-loading firearms.

2219 J. Dawson and T. C. Fawcett, Leeds. Improvements in raising gigs.

2220 W. Currie, Edinburgh. Improvements in manufacturing and fastening the soles and heels of boots and shoes.

2221 W. H. Gosling, Calthorpe-street, Middlesex. Improvements in sewing machines.

2222 J. Rowley, Wells-street, Camberwell, Surrey. Improvements in the manufacture of certain coal tar products.

2223 W. H. Stone, Dulwich-hill, Surrey. Improvements in arrangements and apparatus for taking, counting, and recording votes by ballot.

2224 J. Green, Lisburn, Down. Improvements in the manufacture of ropes, cords, and twines, and in the machinery therefor.

2225 W. Warren, Jersey, Channel Islands. Improvements in ships' anchors.

2226 W. Bull, Waltham Cross, Essex. Improvements in velocipedes.

2227 W. A. Gilbee, South-street, Finsbury, Middlesex. An improved method of preserving the aromatic principle of hops.

2228 W. Dennis, Aldermanbury, City. Improvements in letter boxes, letter pillars, and such like depositories.

2229 W. K. Stock, Darlington, Durham. Certain improvements in looms for weaving.

2230 J. Walsh, Manchester. Improvements applicable to hoods for invalid perambulator and other vehicles.

2231 J. G. Wilson. Improvements in velocipedes.

2232 R. Boyd, Strand. Improvements in boilers and furnaces for producing superheated steam.

2233 T. Barnes, Whitehaven, Cumberland. Improvements in the treatment of coal for the removal of the sulphur compounds contained therein.

2234 J. Hayward, Eckland Bridge Works, near Penistone, Yorkshire. Improvements in the manufacture of combs.

2235 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in telegraph wire insulators.

2236 W. Laing, Carron Vale, Stirling. Improvements in washing machines, which improvements are also applicable to churns.

Dated July 23, 1869.

2237 W. Morris, The Avenue, Blackheath, Kent. Improvements in points or switches for tramways.

2238 W. Lincolne, John-street, Glasgow, and E. Chafer, Thistle-street, Glasgow. Improvements in the manufacture of artificial marble or stone, which improvements are also applicable in the manufacture of the beds of billiard and bagatelle tables.

2239 E. Stevens, Gordon House, Margate, Kent. Improvements in cooking, in the means and articles employed, suitable either for roasting, baking, toasting, or broiling.

2240 J. H. Johnson, Lincoln's Inn-fields. Improvements in the joints of pipes and tubes.

2241 J. H. Johnson, Lincoln's Inn-fields. Improvements in purifying alcohol and paraffin, and in the apparatus employed therein.

2242 G. T. Bousfield, Loughborough, Park, Brixton, Surrey. Improvements in the harness motion for power looms.

2243 S. Bishop, Great St. Helen's, Lancashire. Improvements in lamps for burning paraffin oil and other hydrocarbon oil.

2244 S. Cotton, Brookfield Foundry, Crumlin-road, Belfast. Improvements in machinery for hackling flax and other fibrous substances.

2245 W. Mort, Fenchurch-street, City. Improvements in refrigerating and freezing apparatus.

Dated July 24, 1869.

2246 I. Frankenburg and S. Phillips, Manchester. Improvements in the manufacture of hats and hat bo lies, or other coverings for the head.

2247 H. Greaves, Abingdon-street, Westminster. Improvements in the construction of the permanent way of railways and tramways, and the carriages and engines used thereon.

2248 W. Dredge and A. Stein, Buckingham-street, Adelphi, Westminster. Improvements in machinery for propelling carriages, part of which improvements are applicable to the transmission of power between shafts which are not parallel to one another.

2249 R. Pictet, Rue Jean Goujon, Paris. Improvements in the building of pumps in general, which permit their working without pistons and oil.

2250 J. Dewe, Toronto, York, Ontario. Improvements in mail bags, and in apparatus for fastening such bags, boxes, and other receptacles, where the security of a seal is required.

2251 C. L. Caldesi, Pall Mall East. Improvements in collars and false collars for horses and all other beasts of burden.

2252 G. N. Blane, Glasgow. An improved machine for morticing timber.

2253 R. G. Lowndes and J. Reid, Auldhousefield Mill, Renfrewshire. Improvements in the manufacture of textile fabrics.

2254 T. Auchincloss, Glasgow. Improvements in apparatus for heating feed-water, and for feeding the same to steam boilers.

2255 C. Y. Michie and G. W. Murray, Banffshire, Scotland. Improvements in pillars or standards for straining and supporting wires for fences and other useful purposes.

2256 W. Tongue, Brixton, Surrey. Improved means, apparatus, and furnaces for generating steam with economy in fuel.

2257 D. H. Brandon, Rue Gaillon, Paris. Improvements in metallic cartridges, their primers, and in the methods of manufacturing the same.

Dated July 26, 1868.

2258 W. Crossley and J. W. Swithenbank, Bradford, Yorkshire. Improvements in shuttles.

2259 T. Winter, Wiveliscombe, Somersetshire. Improvements in machinery for combing reeds.

2260 J. Holding and J. Eccles, Manchester. Improvements in looms for weaving.

2261 J. G. Rollins, Old Swan Wharf, Upper Thames-street, City. Improvements in combined reaping and mowing machines.

2262 J. Hyde, West Bromwich, Staffordshire, and J. Hyde, Warwickshire. An improved safety lamp for preventing explosions in collieries.

2263 E. Attenborough, Nottingham. Improvements in means and apparatus employed in the manufacture of looped or knitted fabrics.

2264 B. Hunt, Serle-street, Lincoln's Inn. Improvements in valves.

2265 C. Cochrane, The Ellowes, Upper Gornall, Staffordshire. Improvements in the preparation of iron ores for smelting, and in kilns or furnaces employed for that purpose.

2266 W. W. Roberts, Portland-road, Notting Hill, Kensington. Improvements in the construction of furniture and fittings, also in cornices, skirtings, walls, and ceilings of buildings generally, for the prevention of bugs.

2267 E. Ginder, Aston-juxta-Birmingham, Warwickshire. Improvements in breech-loading firearms.

2268 W. E. Tilley, Kirby-street, Hatton-garden, Middlesex. Improvements in coating or electro-plating iron, copper, brass, lead, and other metals, with tin.

2269 J. H. Johnson, Lincoln's Inn-fields. Improvements in the treatment of night soil and other waste products, and for the manufacture of manure therefrom.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, AUGUST 6, 1869.

THE NEW CANADIAN PATENT LAW.

THE selfish spirit in which the Canadian Patent Law of 1849 and its successors was conceived has long been fully appreciated by British inventors, but it was confidently anticipated that advantage would have been taken of the opportunity created by the enactment of a new law, rendered necessary by the recent consolidation of the several provinces of North America into one Dominion by the Legislature, to reconsider the terms on which patents for inventions should be granted to non-resident inventors. The manner in which this opportunity has been used will be seen by reference to the text of the new Act, which we have been enabled to lay before our readers in our last and present issue. Under the Canadian law, which the Act that came into force on the 1st of July has repealed, patents were granted to inventors being subjects of Her Majesty and inhabitants of the province; and also to importers of inventions similarly qualified, provided they obtained a knowledge of the imported invention while travelling in a foreign country; but inventions of British origin, and those emanating from the United States of America were expressly excepted from protection.* To remedy the injustice of this provision of the law, the interposition of the Colonial Office was sought, the present Lord Chancellor (then Solicitor-General) undertaking, if we remember rightly, to lay the case before the Colonial Secretary. At that time, however, the relations between the Home and the Colonial authorities were on a very different footing from those which at present obtain, and the very idea of interfering with colonial legislation was considered the height of rashness. Nothing was, therefore, done to remedy the evil which the law inflicted upon British inventors, and they were left to buoy themselves up with the hope that a wiser and more Christian spirit would in time prevail, when Canada would, like other countries, invite to her shores the ingenuity of all nations. We have now, however, received the answer to our hopes.

Through a defect in the old law, means were found of making it apply, to a limited extent, to non-Canadians; and inventors of whatever country, on visiting the provinces, were enabled to obtain, through a personal application, protection for their improvements. But they are now effectually debarred from this privilege, as it is only residents of one year's standing who have the right to apply for protection under the new law. It would be difficult to speak too strongly of the folly of this provision; for, while acknowledging the benefits of patent law protection, the Legislature has taken the most effectual means of keeping new industries out of the country. This they have done with their eyes open, and in direct opposition to the advice of their Commissioner of Patents, as will be seen by reference to the letter of our correspondent, Mr. Fordred, published in the present number of the MECHANICS' MAGAZINE. In his letter, the writer gives extracts from the last annual report of the Minister of Agriculture (acting also as Commissioner of Patents) in reference to the contemplated alteration of the law, in which he urges the desirableness "of assimilating our laws more closely to those of the nations now at the head of civilization."

We are glad to find that the subject has already been noticed in the House of Commons. On Tuesday evening last, Mr. James Howard called the attention of the Under-Secretary of State for the Colonies to the terms of the new Canadian Law, with the view of obtaining from the Government an expression of opinion as to the policy of postponing the assent of the Crown to the Act, and thus giving an opportunity to the Canadian Legislature to reconsider its provisions. The answer elicited was eminently unsatisfactory; and it is possible that, through the speedy termination of the session, the opportunity for bringing pressure on the Colonial Office, while there is yet time to object effectually to the Act, will pass away. We trust, however, that this notice will not be without result, and that the Dominion of Canada may yet be saved from the effects of the suicidal policy to which it has clung for the last twenty years. As a mere matter of right, we think that British inventors might claim protection in Canada for their discoveries; for it seems monstrous that a local Legislature should be allowed to deny to their fellow subjects privileges which they enjoy in every other part of Her Majesty's dominions—to say nothing of all foreign countries where the policy of patent laws prevails. It is some satisfaction to know that this act of injustice cannot be maintained without the concurrence of the home authorities; and that public opinion is now far more efficient in keeping governmental departments up to their duties than when the unavailing attempt above referred to was made to teach the Canadians the obligations of common justice.

* This strange provision was first enacted in 1851. I appears to have been gradually developed, for in a rough copy, now before us, of the Bill of 1849, any discoverer, "whether a subject of Her Majesty or an alien," was to receive a patent; but in the progress of the bill through the Legislature these words were altered and the following clause was added, "Nothing herein contained shall extend to inventions or discoveries of any new or useful art, machine, manufacture or composition of matter . . . . discovered or used in the United States of America, or in any part of Her Majesty's dominions in America" (12 Vic. cap. 24, sec. 18). The law of 1851 altered the above proviso, making it extend to "any part of Her Majesty's dominions in Europe or America."

THE ROYAL AGRICULTURAL SOCIETY'S SHOW AT MANCHESTER.

THIRD NOTICE.

IN stone-dressing machines we have, besides that already described, an improved form of Golay's diamond millstone dressing machine, which was exhibited at the well-filled stand of Messrs. Bryan Corcoran and Co., of Mark-lane, London. One of the greatest difficulties hitherto experienced by even the most efficient workmen in working diamond millstone dressing machines has been in keeping millstones in "floor," or in a perfectly true plane. Obviously, no machine can be expected to keep a stone in absolutely true face if any part of the apparatus rests on or is dependent on the face of the millstone itself. Messrs. Corcoran have patented an improved machine on Golay's system, whereby these defects in existing machines are removed; and it appears to leave nothing to be desired where complete efficiency, accuracy, and simplicity are the objects in view. Anyone who can trace up a millstone spindle is able to set this machine ready for dressing, and when once fixed a child can work it, as the stone is brought to the absolute truth of the plane on which the diamond revolves, and not, as in other cases, the machine to the stone. This can be easily understood by the following explanation of the principles of its construction. The machine consists, first, of a short vertical spindle or cone, which is fixed in and having its sole bearings in the eye of the millstone; or, in the case of a bedstone, on the square of the stone spindle. The vertical spindle is fixed so as to carry a boss, from which radiates an arm set to the required angle corresponding to the drift. On the arm the tool carriage moves, producing the rectilinear cracks or cuts as desired on each land in succession. It will thus be seen that the apparatus is adjusted on the principle of the "Jack-stick," and when fixed for work cuts exactly as it is set to do, with a precision unattainable by any other known system. The diamond revolving in each quarter on an arbitrary plane is independent of the judgment of the operator. From the simplicity of the machine it can be made entirely self-acting.

Whilst on this class of machinery, we may refer to the stone-dressing machine for delf stone, freestone, marble, or granite, which was exhibited by the inventors and makers, Messrs. Coulter and Harpin, of Thongsbridge, near Huddersfield. The machine consists of a circular iron table, revolving at great speed, on which the flags or stones are laid. Across this is a reciprocating frame, carried on rollers, which can be raised to any height, according to the thickness of the stones on the table, and sufficiently high to work clear of the stones. The top flags or stones are put loosely into the frame, face downwards, and are carried backwards and forwards whilst the bottom flags are revolving, water and sharp sand being added. Thus great friction is produced, and two faces are worked at the same time. These machines are working in England and Scotland, and they are now becoming generally adopted for mason's work, dressing large blocks of ashlar, heads, sills, and steps on one or all sides, and in nothing is so great a saving effected as in the dressing of small wall stones for fronts of buildings. A quantity of these can be wedged together in the top frame face downwards, and they will be speedily reduced to a true surface.

Messrs. Ransomes, Sims, and Head, of the Orwell Works, Ipswich, had a fine show of ploughs, haymakers, thrashing machines, and various other machines and implements. Their newly patented Star haymaker is a great improvement upon the generality of these implements. In other double-action machines the tines have to be curved to throw the hay over; consequently, when used back-action (for turning the hay) they slip over the green parts, and a portion of the hay is not moved at all. In the Star haymaker the tines are straight, as the forward overhead action is dispensed with, and a quick back-action is introduced, which requires much less draught, and at the same time leaves the hay much lighter than when it is thrown over the machine. It is also fitted with a slow back-action for turning the hay, which brings all the green parts to the surface, and leaves it light and hollow, without breaking off the leaves and seeds. By a simple arrangement the tines can be set at any angle, to toss the hay more or less as required. The Star haymaker is strong and durable, without being heavy. It is fitted with a straight wrought-iron axle and wrought-iron travelling wheels, 4ft. 6in. high. The gearing is placed in the centre of the machine, and is protected by a close case, so that clogging is entirely prevented, and also all risk of breakage in passing through gateways. Both rake barrels revolve when turning at either end of the field, and make several revolutions after the horse stops, thereby clearing a space to start again. From the travelling wheels and rake barrels being both on the same axle, the work is done quite as well in a ridge and furrow field as on the level. The same firm have introduced some improvements in horse rakes. They fit them with large steel teeth, and mount them on wrought-iron wheels 3ft. high, which are capped to exclude dirt. The frames are of wrought iron, and are fitted with side levers, by which the teeth can be raised or lowered to suit the requirements of the work. The teeth can thus be set so as just to skim the ground and prevent any dirt being collected when raking hay or corn, or when required for raking weeds, they can be set deeper into the ground. A bar is attached to the frame, by which each alter-

nate tooth can be taken up when raking corn, to prevent any stones being collected. A seat, on an improved principle, giving ample leverage, has been designed. By this arrangement the driver can ride or walk at pleasure, as the ordinary hand lever is not removed when the seat is added. Messrs. Ransomes had also a very good specimen of enginework in a 14-horse power portable expansion engine, which was driving Messrs. Allen Ransomes' wood-working machinery. It worked very smoothly and with a great economy of fuel, being designed to meet the increasing demand for steam for motive power where coal is not indigenous and where wood is becoming scarce.

The great point of attraction at the Royal Agricultural Show was a large clock tower, in the centre of a square plot, between the implement ground and that set apart for animals and produce. In this tower, Messrs. J. Bailey and Co., of Salford, exhibited a turret clock, which was of special benefit to those who went to the Show. The many peculiarities of the clock we cannot now enter into, except simply to state that it seemed exceedingly strong and well made, and that the design of it is that known as R. Roberts, the celebrated inventor, and of which J. Bailey and Co. make a large quantity. It may here be mentioned that Richard Roberts was the first to introduce cast-iron wheels into his clocks, a system which has since been ably advocated by Mr. E. B. Denison in his book, and which compared with brass are infinitely more durable. One great peculiarity about the clock was the manner in which the hours were struck by means of a centrifugal hammer. This—so the makers say—reduces the motive power required about 50 per cent. A drawing of the clock is being prepared for us, and we will shortly give a more full description of it. The brass fittings for engines and boilers were displayed in great profusion on the handsome piazza under the clock dials. Of the other exhibits of Messrs. Bailey and Co., we may say their name was legion, for the stand was a small show itself, exhibiting a variety of useful inventions patented by that firm. There were regulating tallow cups, oil syphons, low-water alarms, speed indicators, pressure and vacuum gauges, tell tales and peg clocks, alarm signals, and all sorts of indicators, for the special purpose of recording the neglect of watchmen, engineers, stokers, mining cage tenters, and for generally protecting life and property, and promoting statistics for the special benefit of proprietors of steam power. We especially noticed Shaw's patent bar-iron cropper, which will cut ¾in. bar iron with ease. This is a new tool, which will be found useful to the smith and others who use from ¼in. to ¾in. bar. There was also Calow's patent safety cage for collieries, warehouses, and hotels, which is made by Messrs. Bailey and Co., and its simplicity of action caused much admiration, and we are glad to learn that many orders were booked on the ground for it. We propose illustrating this apparatus shortly. It appears that the Clay Cross Colliery Company, after trying it, made arrangements for the right to use it to all their pits for the full term of the patent. We understand that over one hundred are now at work.

The patent chronometrical regulator for steam engines at Messrs. Bailey and Co.'s stand attracted considerable attention. The regulator is a pendulum, which, in a most simple manner, is actuated by the engine, and in connection with it is a lever, which maintains a perfectly fixed position so long as the speed of the engine is exactly uniform with the strokes of the pendulum. This lever is connected to the throttle valve or starting gear in combination with any ordinary governor, and the moment the engine varies, by the friction of a stroke from the pendulum, the lever immediately acts upon the valve and prevents further irregularity. The steam engine, by means of this invention, is under as perfect control as a good clock or watch, and it will perform with the same regularity. The Manchester patent powerful hand fire pumps, invented by the chief of the Manchester fire brigade, seem very desirable little machines for all proprietors of property. The Great Western Railway Company have given an order for these pumps for Paddington and other stations. Messrs. Bailey and Co. claim for this pump that, with its copper air vessel all complete, it is the most powerful pump out for its weight. The new tube expander manufactured by this firm (Walker and Stuart's patent) seems a useful tool for boiler makers. One of Norton and Bailey's pressure recorders, for indicating and recording steam and water pressure, was at work on the ground indicating the town's water pressure. There are many improvements in this recorder, which were kindly pointed out by Mr. N. H. Bailey, the inventor; one great peculiarity is the arrangement whereby the friction of the pencil on the paper does not interfere with the correct working of the instrument—a difficulty which required some scheming to overcome. The patent cavendish tobacco cutter is perfect, and was much admired; the ease with which different degrees of fineness of cut could be obtained is worthy of attention. Before leaving this stand we must allude to one more novelty, out of many others for which we cannot find space. It is Mr. W. H. Bailey's patent pyrometer, an instrument the manufacture of which has had much attention from that gentleman. Agriculturists were much interested in the pyrometer for hay stacks, an instrument 8ft. long, for probing them, to enable the temperature to be immediately indicated, in case of spontaneous combustion. They are also useful for corn mills, to enable grain to be tested as to its condition. The question was asked if they would do for coal stacks when large amounts are stored. The only difficulty is that the instrument would not be strong enough to penetrate the coal. Mr. Bailey, however, recommends iron tubes to be built in the stack, so that the pyrometer could be inserted. The pyrometer for cooks are handsome little instruments, and also those for the engineer to indicate the waste heat of boiler flues; about a dozen different sorts were exhibited for every conceivable purpose where heat is employed.

Mr. Robert Boby, of St. Andrew's Works, Bury St. Edmunds, had some very well designed double-action haymakers. His full-sized machine for heavy crops is very light in draught, and well balanced. The arrangement of the driving gear is very simple. The machines are fitted with Mr. Boby's concentric adjustment, covers being provided to prevent the grass winding round the axle. The smaller sizes of these machines are equally worthy of notice for design and finish. At this stand there were also horse rakes of new design, requiring no frame, and in which manual labour is almost entirely dispensed with. There were also a great variety of corn, malt, coal, and gravel screens. Our attention was particularly directed to Mr. Boby's chaff-sifter, which perfectly sifts grown or cut chaff, rendering it more digestible for horses and cattle. It also clears land of small annual weeds very quickly and cheaply. Several of the well-known oval beam iron ploughs complete Mr. Boby's exhibits.

The stand of Messrs. Holmes and Sons, of Prospect-place Works, Norwich, was well filled with the manure distributors, drag-rakes, portable engines, thrashing machines, corn, seed, and manure drills, &c. In their manure distributor the delivery barrel and scrapers are of metal, to prevent corrosion; the spindles all work in brass bearings, and the delivery appears to be perfect for large or small quantities. The horse lever drag rakes are strongly made; the teeth are lifted for clearing the rake of its load in a very simple manner. The portable seed sheller, with dressing apparatus, deserves notice, as having lately been perfected for shelling trefoil as well as clover. The lever corn-drilling machines exhibited by this firm are very light of draught, and are adapted for all descriptions of soil and any required quantity of seed.

Messrs. James Powis and Co., the saw-mill engineers, of the Victoria Works, Vine-street, Lambeth, had an excellent show of wood-working machines. Their general joiners were shown at work; one was tenon cutting, another was cutting moulding, and the third was planing 9-inch boards. All these machines will saw, plane, mould, edge, tongue, groove, thickness, chamfer, mitre, cut tenons, crosscut, and bore. There was also the Messrs. Powis' moulding and planing machine, which has four cutters working outside with the exhibitors' patent disc feed. We also noticed a new endless band sawing machine, cutting up to 12in. in depth, which is fitted with a spring and self-adjusting packing for the prevention of breakage to saws, which is a very material improvement in this class of machine. In addition to the foregoing, there were machines for sharpening straight and circular saws, tenon cutting machines, mortise and boring machines, shaping and moulding machines, &c. Messrs. Powis also exhibited a noiseless disc-fan blower, so constructed as to be capable of being taken to pieces, cleaned, and put together again during the workmen's dinner hour. This is a decided advantage over the old mode of construction, which caused a day's stoppage.

Messrs. John Warner and Sons, the hydraulic engineers of Jewin-crescent, Cripplegate, London, had their usual extensive selection of pumps and hydraulic apparatus of every kind. There was a model of Warner's annular sail wind engine, which has been satisfactorily applied to the purposes of raising and forcing water for irrigation or for the supply of houses. They are also applicable for many kinds of machine work. There was also a model of a water-wheel and double-action pump, which affords an economical means of raising water where a small but constant supply can be obtained with a fall from a spring or river. It is fixed with but four bolts and nuts, and there are only two joints to be made to put it into working order. The sluice valves invented by these exhibitors are to be desired wherever a full waterway is required. As we have before fully described these valves, we need only add that they are particularly simple in construction, and are not liable to become clogged.

At the stand of Messrs. Aveling and Porter, of Rochester, we found an improved steam road roller, to which a silver medal had been awarded. This machine weighs 15 tons, and rolls 6ft. in width. It has two driving and two steering rollers, and turns round in its own length. The front rollers are so contrived as to adjust themselves to the inequalities of the road. This firm also exhibited an 8-horse power agricultural locomotive of the ordinary type, which showed the usual excellent style and finish of their manufacture. A set of patent travelling rope porters for steam cultivation, suitable for the double engine and roundabout system of steam ploughing, fitted with improved steering gear, completed the list of exhibits here, which, if not extensive, at any rate well represented the class of work turned out at Rochester.

While on this class of machinery, we may notice the steam road roller manufactured and exhibited by Messrs. Manning, Wardle, and Co., of the Boyne Engine Works, Leeds. This machine is the patent of Messrs. E. Gellerat and Co., and the machine exhibited at Manchester was a *fac-simile* of those used by them, as contractors, for making and repairing the streets and boulevards of Paris, and the roads of the Bois de Boulogne. In

this machine both its rollers are drivers, and therefore all the weight is available for useful adhesion, so that it will start at once, and ascend a steep incline. It will work equally well in either direction—forwards or backwards, and will pass easily along curved streets, and will turn round in a small circle. It is suspended on springs, and therefore is not liable to injure gas or water pipes or drains under the surface of the streets. It has a "counter," which registers the distance travelled and the work performed. The firebox is of copper, the tubes of brass, and the boiler of best Yorkshire iron; many parts usually cast are of wrought iron; the motion, the driving chains, and other parts, are of hardened steel. Syphon lubrication is provided throughout; the boiler is lagged and covered with sheet iron, painted, lined out, and varnished, the whole machine being finished equal to the best locomotive work.

Messrs. Garrett and Sons, of the Leiston Works, Suffolk, have improved the details of their agricultural self-moving engines since we last inspected them. These engines, which are very light, will draw a thrashing machine and straw elevator with ease, and will pass over soft land and other places where it would be almost impossible to take machinery by horses. The weight of the new engine is but a few hundredweights more than a portable engine of the same power. It can be steered either by a man in front, or a horse can be attached with shafts. The tender carries water and fuel sufficient for ordinary thrashing journeys. Messrs. Garrett have also made some improvements in Haye's straw elevator, by which the height and angle of delivery can be adjusted with much more ease than hitherto. The drills of this firm are in good demand; they combine the merits of the Suffolk corn drill with those of the seed and manure drills. The box in which the grain or seed is contained is made separate from the manure box, so that when the drill is required for corn or seeds without manure, the whole manure apparatus may be removed. This firm also exhibited a very light and simple seed drill suitable for drilling turnips, mangold, &c., without manure, upon the flat and ridge. These implements are in large use in France and Germany, where beet is grown for sugar, under which circumstances such an implement becomes a necessity.

At the adjoining stand of Messrs. Woods, Cocksedge, and Warner, of the Suffolk Iron Works, Stowmarket, were some very good examples of vertical engines, and a large assortment of mills, root pulpers, turnip cutters, horse gear, &c. The vertical engines of this firm are well put together, and possess many special advantages. They occupy less room than any other form of engine, are entirely self-contained, and, requiring no fixing, the expense of brickwork or other form of foundation is entirely saved. They are well adapted for places where space is a consideration, or for exportation, as they can be shipped without disturbing any of the parts. All the details have been designed so as to secure strength with easy access to every part. The main shaft is arranged so that the flywheel may be placed on either side of the engine; thus two machines can be driven at once direct from the engine, one from each end of the crank shaft. The governors, which are on a new principle, are simple but very sensitive, and can be regulated so as to keep the engine at any speed desired. The feed pump is fitted with gun metal ball valves, and an extra valve is placed between the pump and the boiler, and close to the latter, so that the valves of the pump can be examined or even removed without stopping the engine. This firm also exhibited Paterson's centrifugal pump, which is opened at the side of the casing. The valves are thus easily got at, and without disturbing either the suction or delivery pipes.

The "Eureka" smut and separating machine, referred to last week in our list of awards as having obtained the gold medal, was exhibited by Messrs. Nell, Harrison, and Co., of 75, Aldermanbury, London. It is the invention of Messrs. Howes, Babcock, and Co., of New York, and is a new machine which requires more than a passing notice In addition to a perfect scourer, it has two suction separators—one before the scourer which separates from the grain smut balls, chess and other light substances; and the other after, thoroughly cleansing the grain from remaining impurities after being scoured. Each acts independently of the other, depositing two kinds of screenings, one taken from the grain before it is scoured, and the other after, and both cleaned from dust and chaff, and fit to be sold or ground into feed. It has a very reliable shaking shoe, the first screen of which is for the purpose of carrying off any impurities larger than the grains of wheat. The second screen separates the sand seeds, &c.; the machine is therefore a complete grain cleaner of itself. The scouring case is made of sheet cast steel, and the beaters of chilled cast iron, making it very durable. It is constructed on the smooth surface principle, which, by its direct action on the grain, removes all smut and dust that may adhere to the berry, discharging it through the perforated scouring case, perfectly scouring and polishing the grain, and is not liable to break wheat, or lose its scouring qualities, as is the case with rough surface machines. There is a strong current of air taken through the bottom plate of the scourer, discharging the dust through the perforations of the scouring case, and, at the same time, a strong current of air is drawn through the centre of the scourer to the fan above. This is a most important principle, as the scourer is always kept free from dust without a possibility of its coming in contact with the grain during the process of its being scoured. The scourer is enclosed within a circular casing, leaving an inch space, through which there is a current of air passing of sufficient strength to take every particle of dust that escapes from the scouring case directly to the fan, the fan thus absorbing all the dust from the entire machine, which can be conducted out of the mill. For its perfect safety as regards fire by friction, the bridge trees are cast iron, with but two bearings, the steel step at the bottom and the babbitt metal box at the top; always convenient to be got at while in operation, a fact more or less noticed by insurance agents. For its entire reliability in cleaning smutty wheat, no matter how bad, when not absolutely wet, we understand that this machine has been put to the most severe tests repeatedly in Oswego, Albany, Philadelphia, Cincinnati, Chicago, London, and other important milling points within the last three years, and has never yet failed. It may, therefore, be expected rapidly to supersede other machines, and, considering its qualifications, we consider that, when it was awarded the gold medal, that distinction was judiciously and worthily bestowed.

Messrs. Hornsby and Sons, of the Spittlegate Iron Works, Grantham, had no special novelty to show, but, in most of their numerous exhibits, improvements had been made in minor details. And it is this careful attention to minutiæ that make up the sum of perfection and tend to success. If we could select anything for a few words beyond the rest of this firm's implements, it would be a new mower of simple construction and light draught, and which appeared to us peculiarly adapted for cutting difficult crops on uneven as well as on level land. This mower, which is termed the "Manchester," is made in various sizes, both heavy and light. The "Progress" self-raking reaper by this firm is remarkably simple, compact, and light in draught, although strongly put together.

One of the most extensive stands of agricultural machinery and implements was that of Messrs. J. and F. Howard, of Bedford. They had a new arrangement of steam cultivating machinery consisting of 12-horse power self-propelling engine with two winding drums, 5-tined cultivator, &c. The cylinders are placed in the same position as on ordinary locomotive engines, and the power is given off from the engine to the winding drums by open gear. The apparatus can be worked either on the stationary or direct system. There was also at this stand a new steam drill, which has been designed by Messrs. Howard to meet the demand for a corn drill adapted for use with steam cultivating apparatus. This implement has drilled 100 acres of corn this season, and was found in every respect satisfactory. Howard's ploughs were, of course, well represented, and formed a prominent feature on their stand. Amongst the haymaking machines, we specially noted their double-action haymaker, which contains an important improvement, adding greatly to the strength and durability of the machine. The axle carrying the fork barrels, instead of being cranked, is perfectly straight, and also the axle for the travelling wheels. In their British mowing machine, the framework is of iron. The gearing is simple and compact, and the whole weight is carried by the travelling wheels. The machine is strong and durable as well as effective, and, being perfectly balanced, there is no weight on the horses. We understand that the Howard safety tubular boiler is in good demand, and continues to work satisfactorily.

Messrs. Tuxford and Sons, of Boston and Skirbeck Iron Works, Boston, Lincolnshire, had a large show of portable engines, which exhibited the usual excellence of this firm. They have introduced various improvements into the details of construction, which cannot but have our approval. The guides to the slides are made adjustable, so that they can be compensated as they wear away. The packings are well arranged, and a very simple safety valve is used on all the engines turned out by Messrs. Tuxford. Their adjustable brasses for the crank shaft, and which are in three segments, are another good feature. The feed water is heated by the exhaust steam, and there is every appliance for economizing heat. The driver of one of these engines, which was in motion at the Show, told us he could hardly keep the fires low enough, and this fact was verified by the appearance of the fire at the time, which was exceedingly low, although full steam was kept. Altogether, these engines showed themselves in every way satisfactory, as did also the thrashing machines exhibited by this firm, in which, as well as in the engines, several useful improvements have been introduced.

The old and well-known firm of Messrs. Worssam and Co., of the Oakley Works, King's-road, Chelsea, had a collection of wood-working machinery which well sustained the reputation these makers have acquired for this class of machinery. It is not very long since we described and illustrated several of their machines, so that a general reference to their exhibits is all that is here necessary, the especial merits of their manufactures being well known. There was their general joiner, their self-acting saw bench, a large hand mortising machine, and their improved saw sharpener. Messrs. Worssam have lengthened the table of their general joiner, and have arranged it to cut curvilinear moulding, and it will do work 11in. by 4in. The gut is also done away with, and the machine is now working with straps, which is an obvious advantage.

The stand adjoining that of Messrs. Worssam was occupied by Messrs. Tangye Brothers, and Holman, of Laurence Pountney-lane, London. Here we found their special steam pump in every variety of size; one of these, adapted for raising sewage, was at work lifting some 60,000 gallons per hour. This firm also exhibited a 1-horse power

engine of good construction, and fitted with Tangye's patent governor, respecting which we shall shortly have something more to say.

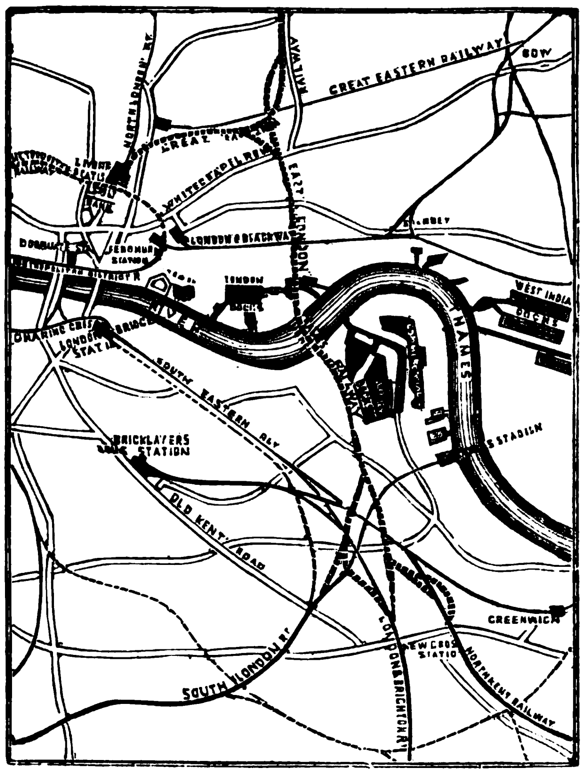
Messrs. D. Adamson and Co., of Newton Moor Iron Works, Hyde, near Manchester, exhibited a portable engine which embodied some special features. It had a solid welded circular firebox, a novelty well worthy of notice. There were other examples of this manufacture, in the way of a Cornish boiler, in which the shell plates were made in solid rings; the flue was also made in solid rings, with Adamson's flange seam and with conical tubes welded in. The finish of the work was all that could be desired, and the principle is one of importance in boiler work.

The remaining exhibits of which we have to speak must of necessity be summarized, owing to the great length to which our notice of this unprecedentedly extensive show has run. To make a beginning of the end, then, let us first mention some excellent turbine water wheels and silent blowing fans, on Schiele's system, exhibited by the Union Engineering Company, of 2, Clarence-buildings, Booth-street, Manchester. This company are sole proprietors and manufacturers of Schiele's patents of 1863 and 1867, which are well represented in the examples under notice. Mr. G. Z. Scott, of St. Mary's Gate, Manchester—whose wheel moulding machine was recently described and illustrated in the Mechanics' Magazine—exhibited an apparatus for this purpose of a size to mould, spur, bevel, and mortise wheels without patterns from 12in. diameter up to 4ft. 6in. diameter, and 12in. broad. The apparatus attracted the attention of all passers, and we heard some well-merited encomiums bestowed upon it. Messrs. Gregory and Haynes, of St. Stephen's Works, Salford, had a good show of brewing utensils of the latest design and containing many improvements. Their seamless copper steam coil for a ten-quarter brewery is well worthy attention from the efficient principle of construction adopted. Mr. John Cameron, of the Egerton-street Iron Works, Hulme, Manchester, had several very good portable engines on feet, as well as some powerful punching and shearing machines. The peculiarities of the engines are such as deserve a more extended notice, for which we reserve them.

Messrs. Clayton, Son, and Howlett, of the Atlas Works, Harrow-road, London, were busy making bricks with clay off the Show ground, in one of their direct-action brick-making machines, which admirably illustrated their system of manufacture. Mr. John Weighell, of Pickering, Yorkshire, had some good portable engines, grinding mills, and straw cutters. The chief attraction here, however, was Storey's indicator, particulars of which will be found on another page. At the stand of Messrs. Pooley and Son, the well-known weighing machine manufacturers of Liverpool and Manchester, we found, amongst other things, an exceedingly useful and correct machine. This was their automatic grain weighing and registering machine, which weighs, records, and discharges, by the sole momentum of the grain in the process of being weighed. Paints were represented by Messrs. Walter Carson and Sons, of Belle Sauvage-yard, Ludgate-hill, who had samples and patterns of their anti-corrosion paint, which is specially prepared for resisting the weather, and which does not blister under the sun. And last, though not by any means least, we found the attractive stand of Mr. T. B. Ayshford, of the Britannia Carriage Works, Fulham. Here was the celebrated canoe waggonette, which affords ample sitting room for eight persons. Ingress and egress are obtained at the sides instead of the back, as in the ordinary waggonette. This vehicle, although so commodious, weighs less than 8cwt., and is of very elegant design.

We can only conclude as we commenced, by observing that the late Show at Manchester was a success in every sense of the word. This it deserved to be, as the executive spared no pains to promote the interests of the exhibitors and the comfort and convenience of the public. The results are to the lasting credit of the exhibitors and of the Royal Agricultural Society of England.

THE EAST LONDON RAILWAY ROUTE



THE SOCIETY OF ENGINEERS AT THE EAST LONDON RAILWAY WORKS.

The works of the East London Railway present several features of interest to engineers, and by permission of Mr. Hawkshaw, the members and associates of the Society of Engineers visited them on Friday last. On this occasion, the executive was represented by Messrs. F. W. Bryant (President), J. H. Adams (Member of Council), A. Williams (Hon. Sec.), P. F. Nursey (Auditor), and G. W. Harris (Secretary). Amongst the members were Messrs. J. Westwood, W. T. Hendry, J. Bernays, A. E. Stephenson, F. Colyer, P. Jensen, H. Gore, &c. On assembling at the Wapping shaft of the Thames Tunnel, the visitors were received by Mr. Hawes, the Chairman of the East London Railway Company; Mr. Cooper, the Secretary; and Mr. Burleigh, the resident engineer in charge of the works. The course of the line, with its various branches and ramifications, will be clearly seen from the annexed block plan, upon which it is indicated by dotted lines. Starting from the Liverpool-street station, where it will be in communication with the North London and Metropolitan Railways, the railway will run to Whitechapel-road, where a junction will be established with a branch running into the Great Eastern Railway. The line will then cross the Whitechapel-road and the London and Blackwall Railway, proceeding thence nearly in a straight line to the river, which it will cross through the Thames Tunnel. The line as at present laid out and nearly completed, commences at the Wapping end of the Thames Tunnel, through which it proceeds, running past the Grand Surrey Canal Docks and through Deptford to the Old Kent-road station of the South London Railway. A branch which leaves the line near Rotherhithe runs to New Cross, where it communicates with the North Kent and the London and Brighton Railways. The Surrey Cana is crossed by these two lines, in each case by a lattice girder bridge of 80ft. span, with two side openings of 13ft. span each. On another page of our present issue, we have illustrated and described one of these bridges in detail. So far, the line is nearly ready for opening, a preliminary notice to that effect having been given by the company to the Board of Trade. The works remaining to be executed consist of that portion of the line between Wapping and Liverpool-street, which latter place will eventually be the terminus of this railway. The completion of this section of the line, however, will occupy about two years, the works upon it being of an unusually heavy nature.

There is a heavy piece of bridge work at Cross-street, Rotherhithe, which bridge carries the main road, and is divided by cast-iron columns into two spans of 25ft. each. The piers are of the ordinary description of brickwork, laid on cement concrete foundations, with proper offsets; and each pier has a 4-inch drain pipe passing through from top to bottom to carry off surface water, and this discharges into a 9-inch vitrified pipe, which latter discharges directly into the main sewer in the road. Asphalte is carried down the end of the arch and bed stone, and wherever its use is found desirable. The asphalte is laid on in two coats of ¾in. each, and then covered in. The parapets are of brickwork, 10½in. in thickness, and the coping is of Bramley Fall stone moulded. The girders are of cast iron, of the ordinary description, 2ft. 2in. high—the facia girder being straight, and the inside tapering from 2ft. 2in. at centre, to 1ft. 6in. at bearing points. The girders are in lengths of 27ft. 6in., and butt on the centre of the columns. The cross girders are of cast iron, the web of each being 1⅜in. thick, the bottom flange being 1ft. 10in. wide, 2¼in. thick, and the top flange 8in. wide, and 1¾in. in thickness. Lewis bolts are used in all the girder work. The cast-iron columns are of a handsome pattern, standing on a surface of brickwork in cement; the diameter of the castings is 12in., the capitals are appropriate, and are secured to the stem by lewis bolts and nuts. The cross arches between the cross girders are of brick in Portland cement, and asphalted.

It will be seen that the East London Railway will unite the Brighton, South London, South-Eastern, and North Kent Railways, accommodating in its course the Surrey and Commercial Docks, the London Docks, and the east of London. The London and North-Western Railway will also be brought into this system. The line will thus open up the important districts of Rotherhithe, Wapping, Deptford, St. George's-in-the-East, Limehouse, Stepney, Whitechapel, Bethnal Green, Bishopsgate and Shoreditch, thereby affording an outlet by the principal railways of the kingdom for the most densely populated parts of the metropolis. The terminus, to be erected in Liverpool-street, will be in the very centre of business—close to the Bank and Royal Exchange, and it will, no doubt, command for this line a vast share of the omnibus traffic. Mr. J. Hawkshaw is the engineer-in-chief of the line, the contractors being Messrs. Brassey, Wythes, and Lucas, Brothers. It may be interesting to add that the Thames Tunnel, which was opened on August 2, 1843, was closed on Wednesday week, having thus been a public footway for nearly twenty-six years. It was purchased for £200,000 (one-third of its cost) by the East London Railway Company. The works of the Thames Tunnel were commenced in 1825, but physical and financial difficulties delayed the opening for eighteen years.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

A PROCESS FOR TINNING IN THE WET WAY—TO DETECT SMALL QUANTITIES OF ALCOHOL—THE SOLUBILITY OF SULPHUR IN THE COAL TAR OILS —HOW TO BLEACH IVORY.

VESSELS of brass or copper can be easily tinned in the wet way by the following process, devised by Dr. Hiller:—A solution is made of one part of crystallized protochloride of tin and ten parts of water. Another solution is prepared with two parts of caustic soda or potash, and twenty parts of water, and the two solutions are mixed together. The mixed liquor will be milky at first, but will become clear after a time. The utensils or objects to be tinned are placed in a proper vessel with a sheet of pure tin perforated with a good many small holes, the alkaline solution is poured over them, and then heat is applied while they are occasionally moved about with a rod of zinc. The tinning is effected very rapidly, a few minutes being sufficient for the deposition of a bright coating of the metal.

The detection of minute quantities of alcohol is not difficult by some well-known processes, but the following may be of use to some, as the re-agents will be found in every laboratory. A few drops of the suspected solution are placed in a test tube with a small quantity of iodine, and a few drops of caustic soda or potash, and a gentle heat is applied. If any alcohol is present, a very characteristic yellowish crystalline precipitate of iodoform will be thrown down. By this process, Lieben tells us, one part of alcohol in two thousand of water may be recognized.

The solubility of sulphur in the coal tar oils has been made the subject of a long series of experiments by M. Pelouze. The results may be summed up in a very few words: the solubility increases with the density of the oil and the temperature. Thus 100 part of a light benzole, sp. gr. 870, and a boiling point from 80deg. to 100deg. C., will at the ordinary temperature dissolve only 2·1 parts of sulphur, and at 100deg. C. not more than 15·5 parts. But a heavy oil, having the sp. gr. 1·020, and boiling from 220deg. to 300deg., will at the common temperature take up 7 parts of sulphur, and at 100deg., 54 parts. At higher temperatures the heavy oil will dissolve an indefinite amount of sulphur, but above 200deg., decomposition of the oil takes place, and sulphuretted hydrogen is evolved. The best oil for extracting sulphur would appear to be one which has the density ·995, and boils from 180deg. to 210deg.

A process for bleaching ivory is given by Dr. Artus. He specially mentions the application to ivory plates for pianoforte keys; but it will of course be applicable to all articles of the material, which is so liable to acquire a disagreeable dark colour. The articles are first to be soaked in a solution of carbonate of soda (half a pound of the crystals to two pounds of water) for a couple of days. They are then to be well rinsed with clean water, and afterwards transferred to a solution of three-quarters of a pound of sulphite of soda in two pounds of water, in which they must remain for five or six hours. Then, without removing the ivory, a mixture of one ounce of hydrochloric acid and four ounces of water is to be added, the whole is to be stirred together and the vessel covered up and left for thirty-six hours. At the end of this time, the solution is poured off and the ivory is to be well washed with water. If it should not have the desired whiteness, the process may be repeated. The proportions of solutions we have given above will suffice to bleach a pound of ivory.

PARLIAMENTARY NOTES.

ON Monday last, in the House of Commons, Mr. Macfie inquired whether the statement in the public press, that amongst the measures contemplated next session there was one for a reform of the patent laws, referred to any measure contemplated by the Government, and if so, whether that legislation would be preceded by an inquiry either by a committee of the House or by Royal commission.

Mr. Bright believed that every member of the Government would agree with his hon. friend that some considerable change was necessary in the patent laws. He was not sure how many, or whether any of them were of opinion that there ought to be no patent laws. But notwithstanding the agreement as to the desirableness of some alteration, it would be very imprudent for him to pledge the Government to bring in any measure of this nature when there was so great a difference of opinion, and when it seemed impossible that no two men could agree as to the change. If a committee or a commission were appointed there would be a difficulty as to whether they should inquire what amendments should take place in law, or whether there should be any patent system at all. Admitting that the question required to be attended to, whenever there was time to attend to it, he was quite unable to say that the Government would pledge itself to bring in a bill on the subject next session. If his hon. friend would propose the appointment of a committee that would be a reasonable proposition, and it was probable that both the Government and the House would accede to it.

Mr. Macfie gave notice that if the Government did not introdcce a bill on the subject at the beginning of the next session, he would propose the appointment either of a committee or a commission.

Mr. Gourley asked the Under-Secretary of State for Foreign Affairs if he had received any official information as to the probable navigable depth of water expected in and through the Suez Canal; and when it was to be opened for general commercial purposes.

Mr. Otway said he would give his hon. friend all the information that was in the possession of the Foreign Office, but he must remark that it was not official. Mr. Fowler, the engineer, was in Egypt at the beginning of the year, and he reported that the canal was originally intended to have a depth of 28ft., but that its depth was now 26ft. The first and most difficult section consisted of 22 miles. It had 190ft. of surface width, with a depth of 26ft., and 72ft. broad at the bottom. The second section consisted of 77 miles, with 327ft. of surface width, a similar depth of 26ft., and a width of 72ft. at the bottom. But they had heard from other sources that the depth did not exceed 18ft. The opening of the canal had been fixed for the 17th of November, but he doubted whether the works were so far advanced as to admit of being opened at that date.

At the same sitting, Captain Beaumont asked the Secretary of State for War that inasmuch as a considerable section of the House was opposed to the outlay contingent on the Spithead forts being constructed to mount two tiers of guns in place of one, whether he would be willing to reconsider the propriety of reducing the scale on which the forts on the Horse Sand and No Man's Land Sand were proposed to be constructed, and so effect a saving of £225,000.

Mr. Secretary Cardwell hoped the House would remember that, in preparing the bill which had its approval, the whole amount had been reduced below the amount included in the Act of 1867 by £491,000; and if £75,000, allowed by the Act to meet unforeseen contingencies, was included, the total reduction of the amount placed in the schedule to the Act of 1867 was £566,000. This had been accomplished by giving up works not yet commenced, and postponing other works, the construction of which might be considered at a future time. The smaller forts had been reduced to one tier of guns, and with regard to the larger forts it had been considered a more economical arrangement to construct them of two tiers, as originally designed. He hoped the hon. and gallant gentleman would be satisfied with this answer, and the assurance that the works would be constructed with a regard to the strictest economy.

Mr. J. G. Talbot asked the President of the Board of Trade how soon the various railway companies would comply with the provisions of the Act 31st and 32nd Vic., cap. 119, sec. 22, requiring them to provide means of communication between the passengers and the servants of the company; and, whether he could inform the House what the nature of such communication would be.

Mr. Bright replied that on the 1st of August, on all trains to which the Act applied, some mode was established of communicating between the passengers, the drivers, and guard. There were three means of communication, by means of a cord or rope, and one was managed on the electric principle. These had been sanctioned by the Board of Trade. Of course the board could not say positively whether the plans were perfect and satisfactory, but they had met so entirely the views of those most conversant with railway matters that the board had sanctioned them, and they had reason to believe that they would do all the Act intended.

In the House of Lords, on Tuesday, the Earl of Morley, in moving the second reading of the Nitro-Glycerine Bill, said its provisions were of a very stringent nature, but it contained a clause to the effect that if hereafter any compounds should be discovered that would render that substance harmless the stringency of those provisions might with respect to those substances be relaxed.

Lord Cairns had a petition to present against this bill, which he did not think ought to be allowed to pass without great modifications. The Government spoke of certain compounds to render nitro-glycerine harmless that might hereafter be discovered; but if they had made inquiries they would have found that some of those compounds were in daily use, and were perfectly harmless, and that explosions were nearly, if not altogether impossible. One of these substances was dynamite, and the petition he held in his hand was from a Welsh company engaged in its manufacture, who set forth that it was nearly as strong as pure nitro-glycerine, and much stronger than gunpowder, but that it was perfectly harmless, and being a powder, not a liquid, was not subject to leakage or to explosion from concussion. They complained that this bill, which prohibited not only nitro-glycerine but every substance into which nitro-glycerine entered, would be a practical confiscation of their manufacture. He (Lord Cairns) understood that dynamite was not the only compound that was in use, but they would all be prohibited under this bill.

The Earl of Morley promised the Government would look into the matter, and pointed out that if their compounds were innocuous, they would be protected under the third clause of the bill.

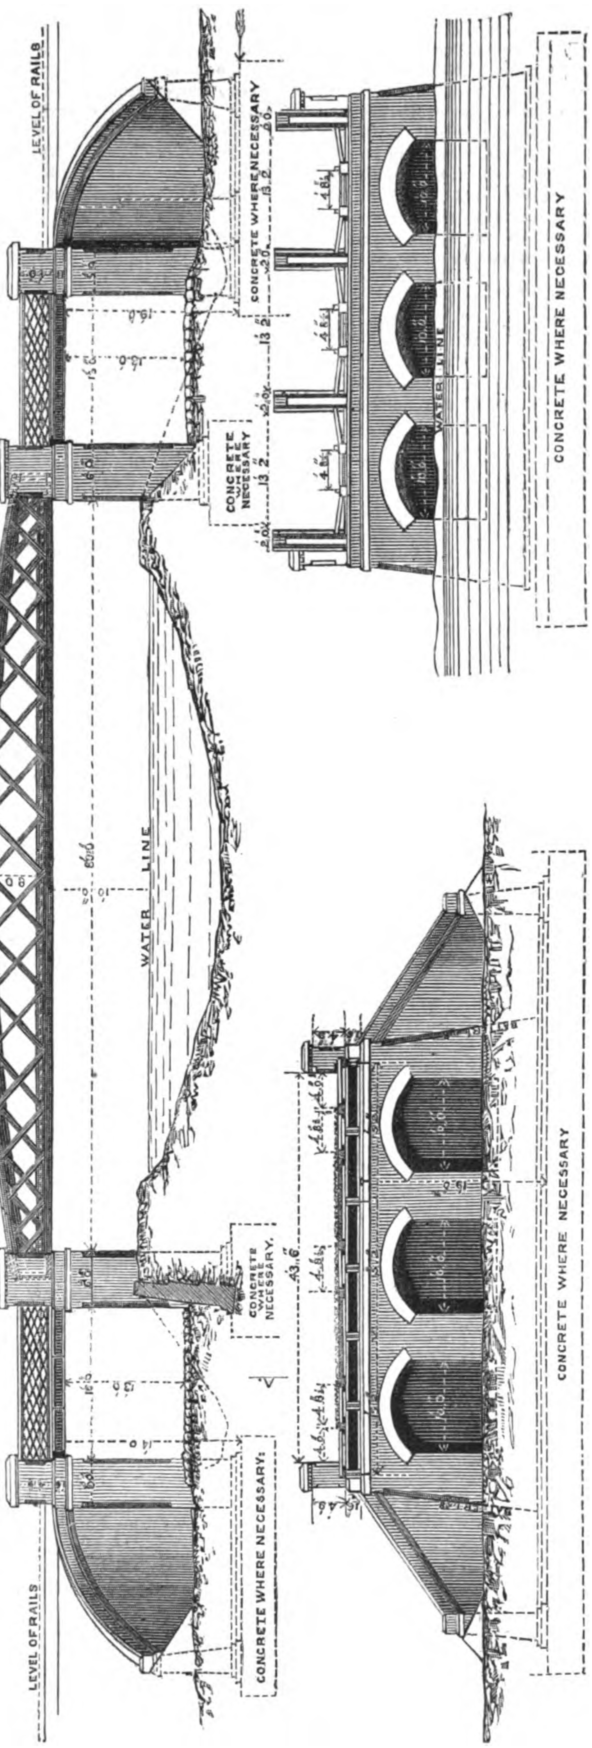
The bill was then read a second time.

In the House of Commons, on the same day, the question of the new patent law in Canada was opened by Mr. J. Howard, who asked the Under-Secretary of State for the Colonies if his attention had been directed to the new Patent Law Act passed by the Senate and House of Representatives of Canada, and to which the Governor-General gave his assent on the 22nd of June last; if he was aware that by the terms of that Act the rights hitherto enjoyed by British subjects and foreigners were abolished, and that, unlike the patent laws of England and all other countries, the benefits of its provisions were limited to persons permanently resident in its own dominions; and whether the Colonial Office was prepared to recommend the Government to advise Her Majesty to withhold or postpone her assent to the Bill with a view to give an opportunity to the Canadian Legislature to reconsider its provisions.

Mr. Monsell replied that no such Act as that to which this question referred had reached the Colonial Office.

EAST LONDON RAILWAY—GRAND SURREY CANAL BRIDGE.

MR. J. HAWKSHAW, ENGINEER.



EAST LONDON RAILWAY—GRAND SURREY CANAL BRIDGE.

THERE are two bridges which carry the two arms of the East London Railway over the Grand Surrey Canal. These structures are similar in design, and their construction will be seen from the annexed engraving. Each bridge has a centre span of 80ft., and two small side spans, each 16ft. The great span carries the railway over the canal, and the lesser spans over two roadways. The head-room from water level to soffit of girder is 10ft. 6in., being ample for the boat traffic. The height from crown of roadways to centre of soffit of girder is 13ft., and at water tables 14ft., so that in passing through the headway will not be interrupted by the bridge. The abutments and piers are built of brickwork, laid in blue lias lime mortar. The foundations are of Portland cement concrete. There are three sets of rails of 4ft. 8½in. gauge, the width in clear of dividing girders being 15ft. 2in. The batter of the piers is 1 in 8. The coping of the parapet is of Bramley Fall stone, neatly moulded. The entire width of the bridge at the points marked *a a*, or over the roadways where no intermediate girders occur, is 43ft. 6in. The wrought-iron lattice girders for the large span are four in number, made for the contractors by Mr. T. Shaw, Cannon-street, 8ft. high in the centre, and 4ft. high at bearing points. The top and bottom flanges 2ft. wide. The width in clear of box plates is 1ft. 3in. Height of girder from out to out, 8ft. Stifners are placed 6ft. apart. The camber of each girder is 2in. The rivets are ⅞in., with a 4in. pitch. The web of side girders is ¼in., and the angle irons 3in. × 3in. × ⅜in. and ¾in. rivets. The flanges are 9in. wide, and ½in. thick. The road openings are spanned by ordinary wrought-iron girders, 1ft. 6in. in depth.

THE BRITISH ASSOCIATION.

WE have already announced that the thirty-ninth meeting of the British Association for the Advancement of Science is to be held at Exeter. The preliminary arrangements for the meeting have just been completed. The meeting will occupy a week, and the inaugural address will be delivered at the opening meeting on the 18th of August, when the president, Dr. Hooker, D.C.L., F.R.S., &c., will resign the chair, and the president elect, Professor Stokes, M.A., D.C.L., Sec. R.S., &c., will assume the presidency. On the next evening (Thursday, August 19), there will be a soiree; on Monday evening a discourse; and on Tuesday evening a soiree. Sectional meetings will be held daily at 11 a.m., except on the opening day—viz., on Thursday, August 19, Friday the 20th, Saturday the 21st, Monday the 23rd, and Tuesday, August 24. The lectures are:—A. Mathematical and Physical Science; B. Chemical Science; C. Geology; D. Biology; E. Geography; F. Economic Science and Statistics; and G. Mathematical Science. The presidents, vice-presidents, and secretaries of each section will be appointed by the general committee on the opening day of the meeting. The place of meeting next year will be fixed on August 23, and the concluding meeting will be held on Wednesday, August 25. Sir Roderick I. Murchison, Lieutenant-General Edward Sabine, and Sir Philip de M. Grey Egerton, are the vice-presidents of the Association.

A NEW GAS-MAKING MACHINE.

LIQUID fuel may now be said to have achieved and established a reputation of being applicable with success to various useful purposes; but, hitherto, comparatively little has been heard of its capabilities as an illuminating agent. The only description of gas produced from mineral oil with which the public is familiar, is the brilliant flame of the long necked and ungainly naphtha lamp, which gives light to the costermonger and his customers in the street markets. Gas made from oil is not a novelty, but we venture to think that a machine which has been patented by Mr. George Flintoff is an improvement upon anything hitherto known or employed in that direction. This new gas-making machine may be made of any size, and, up to a certain size, is portable, and may either remain stationary in a particular part of a building or be carried from room to room as may be required, and as the fittings attached to it may permit. The machine is cylindrical in form, and has a space between an inner cylinder which receives the charge of rock oil and the outer case. From the charge cylinder the oil exudes slowly into the space referred to, at the bottom of which it is absorbed by a layer of wool. The vapour rising from this oil in the saturated wool furnishes the essential element in the gas to be produced; the only other element is atmospheric air, with which the vapour is diluted. The air, which is only introduced into the machine when the consumption of gas is going on, is regulated in its admission by a piece of machinery actuated by a spring barrel movement, similar to that of a spring timepiece. The pump which admits the atmospheric air, and the machinery with which it is connected, are put in motion as soon as gas begins to be drawn off, and the process of manufacturing the gas, the mixture simply of the atmospheric air with the vapour of the oil, at once commences and continues self-acting, as long as the charge of oil lasts, and gas continues to be drawn off. The process is beautifully simple, the gas being made instantaneously, without the application of heat or any

labour or attention whatever. The gas, as we saw it produced, was not very brilliant, but experience as to the qualities of the oils used, and practice in the use of the machine, will probably lead to the production of as high a quality as can be desired. According to the inventor's statement, a gallon of oil at 2s. 6d. will produce 1,000 cubic feet of fifteen-candle gas, and a charge of 3½ gallons will burn for 750 hours through an argand burner. The apparatus is adapted for use in houses, shops, theatres, churches, or other public buildings.

AERONAUTICAL SOCIETY OF GREAT BRITAIN.

(Continued from page 88.)

MR. H. F. ALEXANDER read the following paper on aerial navigation:—

Aerial navigation is a subject which has always to me had a certain amount of fascination about it—one to which my attention was somehow drawn in boyhood, and one which has never, though I have had no chance of carrying out any experiments, lost its attraction. Though my lot has for some years past been cast abroad, I never saw a paragraph in any paper or book about balloons or aerial machines that I did not read with great interest, and when I first noticed the formation of this society I hailed it with a kind of internal satisfaction. The more an intelligent mind examines this subject, the more thoroughly must it be convinced that there is nothing in the laws of Nature which militate against it. True, man has not yet been able to unravel the mystery, but that is undoubtedly due to his ignorance; as his knowledge extends throughout the various branches of science, he may be—he is—yet destined to accomplish it.

The flight of birds proves that the air can not only support a considerable weight, but that it can (a point which has often been disputed) supply a fulcrum for progressive motion, and one which results, too, from physical conditions peculiar to itself, in effect far surpassing those afforded to the steamboat by water, or to the locomotive by the rail. No motion, on land or in water, whether of nature or of art, is so easy, so graceful, and, for its size, so swift, as that of the bird.

What are the requisites for aerial locomotion? They are not many, and, to a certain extent, they are within our grasp. They are, first, a floating or sustaining power; second, light machinery which will successfully act on the air, so as to give an onward motion; and, third, a power to drive this machinery, and the moment that you obtain the power to "move on," you acquire the ability to guide. A sustaining power we already have in coal gas, hydrogen, and others yet more suitable which are still being experimented upon—as exhibited in the balloon. We have propelling machinery on the principle of the screw, and in various devices, as a substitute for wings, some of which have at different times, I believe, been described to you. And a power, equal to all requirements as a power, we have in steam; but—and here comes our great difficulty—the weight of engine, boiler, and water, to say nothing of fuel, is such as to render the use of a steam engine, in the ordinary acceptation of that term, utterly impracticable. Give us, however, a motive power equal to steam, but generated from only a few pounds' weight, and we shall at once have aerial machines on both the wing and screw principle, when practical experience will soon decide which is the most suitable. Such a power man will yet have; such a power our scientific men may yet work out, even in our own day.

But passing over, for a short time, those who are endeavouring to work out these problems, and wishing them every success, just let us take another look at what we actually have, and see if we cannot, even yet, turn it to practical use, even if no more than a working model. Produce but a working model, a model that can be looked at as it travels from one end of a hall to the other; a model that can, by the simple closing or opening of a valve, be caused to proceed in any direction wished, to rise in the air or descend to the floor. Give us such a model, something to close the teeth upon, something to grip, and I will guarantee that John Bull, like his canine namesake, will never loosen his grip till he can throw down this aeronautical difficulty a solved problem at his feet.

Before taking up the question of a model, just let us examine for a few minutes the main principle with which we should have to deal. This principle is that a fluid or gas confined within a given space under certain conditions exerts in every direction a powerful uniform outward force in a ratio proportionate to the conditions. What these conditions are, or what that ratio may be, does not concern our present purpose; we have only to deal with the fact that it is a force, and a uniform force. To explain it in simple language, we may suppose this gas to be confined in a hollow sphere, or, what may be more suitable for our purpose, a cylinder, and that it is pressing equally over all parts of this cylinder. If the pressure is 1lb. to the square inch, and the superficial circumference of this cylinder equal to a surface of 200 square inches, then the one-half of this cylinder would be pressed in one direction with a force of 100lb., and the cylinder would move in that direction were it not that the other half, being of the same area and subjected to the same amount of pressure, presses in the opposite direction with an equal force, and so the cylinder remains stationary. Then suppose each of two ends to represent individually a surface of 20 square inches, then each would oppose the other with an equal force of 20lb., and thus balanced the cylinder would still remain stationary. Now, suppose one of the ends to be knocked out, would not the other end, now released from its opposing and preventing force, move forwards in its own direction? Of course it would, and as long as the force within the cylinder continued undiminished, so long would the end, together with the cylinder, continue to travel with a force of 20lb.

That is the steam engine in its simplest form, and in that form we would suggest its application to aerial navigation. That in this form its force is not generally capable of being economized to anything like the extent to which it can, when applied through the medium of the piston and cylinder, is readily admitted; but if it gives us as much power as we wish in the meantime, that is all that is required. We are working, in a manner, in the dark, and we really do not know the amount of force that we require, but I am very much inclined to believe that it is very much less than is generally supposed; and I base my supposition on, for one thing, the following:—You have all, no doubt, heard of the albatross, and perhaps some of you may have seen it. This last has been my pleasure, and I watched the flight of these birds with great interest. They appeared to rise from the water with difficulty, and must have tripped along the surface some twelve or fifteen yards, with outstretched neck and flapping wing, which awkwardly struck the water before they rose entirely free. During a gale of wind they appeared to require less space, as the wave sinking from below them left them comparatively unimpeded, when a few powerful strokes of their wing soon placed them far beyond the reach of the next. Once fairly on the wing, these were stretched out to their full, and the bird floated rapidly along without any apparent effort. Seen from before or behind, the appearance of the wings suggested the idea of a strung bow. In this manner would they cross the stern of the vessel, keenly scrutinizing the surface of the water to see if anything had been dropped from the ship; they would shoot far ahead, would drop as far astern, would again cross our bow, would strike away from the ship, would skim the surface of the surging wave, the tips of their wings just touching; they would rise to the rising wave, and sink to the sinking one, and to all the ever and sudden shiftings of a heavy sea they would as quickly adjust the line of the plane of their wing—now it was 45deg. on this side, and the next 30deg. on the other. To some sudden gust of the gale they would rise some 20ft. or 30ft. at once, and the next minute they would be soaring above our heads as if to bid us farewell, and then with a few sweeps of their wing strike away for the horizon. Till then, however, what I have described had been done without a single stroke of the wing, without any great visible effort whatever! How is this done? Various explanations have been given as to how this is or may be accomplished, but as these have already been recorded, I shall only mention the following, which I have never seen noticed. In common with other birds, we know that the albatross has the power, and likely to a much larger extent than usual, of inflating itself, and *vice versa*, at will. May it not, therefore, avail itself of this, and, by expelling the air in all its downward motions, and inflating itself again in all its upward, secure a constant surplus force, as it were, fully equal to these results which so excite our wonder, or, shall I say, our envy. I have also observed a motion in the extremes or last joints of the wings, a wavy up and down motion, but hardly perceptible. Could this be sufficient for the purpose?

But it does not concern us so much to know by what means the bird acquires this power; it is sufficient for our present object to know that it has means equal to these results, and the fact that even close observation fails to determine these with certainty, suggests very strongly the idea that the force required must be very much less than what we, from our want of knowledge, have generally supposed. That which the closest observation cannot detect must be very small indeed, and we may, therefore, be encouraged to hope that though the steam power which we suggest should be employed may be comparatively small, it may yet produce results far beyond our expectations. The working model which we would propose we should construct as follows, and if made to work for full ten minutes, we should be very well content. We should begin with the boiler, which, as it would not be required to store much steam, might be made very light indeed. It would only require to contain water sufficient to give a ten minutes' supply of steam, but require a considerable heating surface, so that the steam might be kept up all that time with a good deal of force. It would require five valves; the main one would open backwards, and would thus force the machine forwards. Another would open upwards, and so press the machine downwards. Another would open downwards, and thus press the machine up again, and the remaining two would be required to turn the machine, by forcing the head round either to the one side or to the other, as desired, and thus the machine ought to be under perfect control. Of course, the force would be exerted on those parts immediately opposite the openings by which the steam escaped, and these would be removed to different parts of the balloon or machine, and so distributed over that comparatively bulky object, which should thus be perfectly under command. The steam would be carried up to the points required by light tinsel pipes. Now, the weight of such with boiler, water, and spirit lamps could scarcely exceed a few ounces, and a hydrogen gas balloon could easily be constructed from gold-beater's skin, sufficient to bear up the whole in mid-air. Some such we would suggest as the model; it is simple, it is a machine without machinery, and there appears to be nothing which would imply any difficulty in the construction of such.

A working model once made, and careful experiments carried out, we should no doubt soon acquire an insight into aerial navigation far surpassing any which we now have, and one which would justify the construction of a larger and improved machine for practical experiment. Had we but a motive power equal to steam, but generated from only a few pounds' weight, there would be no difficulty in the matter of a practical machine; but not having that, steam is our great difficulty. Notwithstanding that we propose to throw away the pistons, cylinders, cranks, beams, connecting rods of all kinds, and the large lumbering boiler, retaining only a steam generator, water and fuel, yet even then weight is our great encumbrance. The weight of the water and steam generator or boiler we shall have just to bear, but the weight of the fuel may be overcome by the use of some patent fuel, oil, or gas. It might just happen that coal gas might be found capable of being burned with safety. In this case, the supply of gas might be adjusted in such a way as to equalize the weight of water, and as the gas was slowly consumed so might the water in the same proportion, and thus the relative weight carried by the balloon be kept uniform. When the word balloon is used, you must bear in mind that it refers not to the usual clumsy pear-shaped machine, but to one of a cigar, cylindrical, or other more convenient shape. Such a machine as that to which our paper refers, should be able to ascend or descend, or to maintain a given distance from the surface without any waste of gas or ballast.

(To be continued.)

THE Erie Railway, which is one of the worst managed railroads in the United States, has had another frightful accident. At midnight, July 14, an express train from New York was going westward, along the banks of the Upper Delaware, at a speed of thirty miles an hour, and at a place called Masthope ought to have passed a goods train which was on a siding. The latter, however, stood partly on the main line, and there was a collision, which threw the engine and seven coaches of the passenger train off the track, setting them and a station-house near by on fire. Of course there was a frightful loss of life. The coroner's investigation developed the fact that it was caused by the engine-driver of the goods train sleeping on his post. His train was on a siding waiting for the passenger train to pass by. The sleeping man interpreted the rush of the latter as an order from his guard to proceed, and, suddenly awakening, started his train out on the main line, when the collision occurred.

BRICK-MAKING MACHINE.

BY MR. P. HOOKER.

FIG. 1.

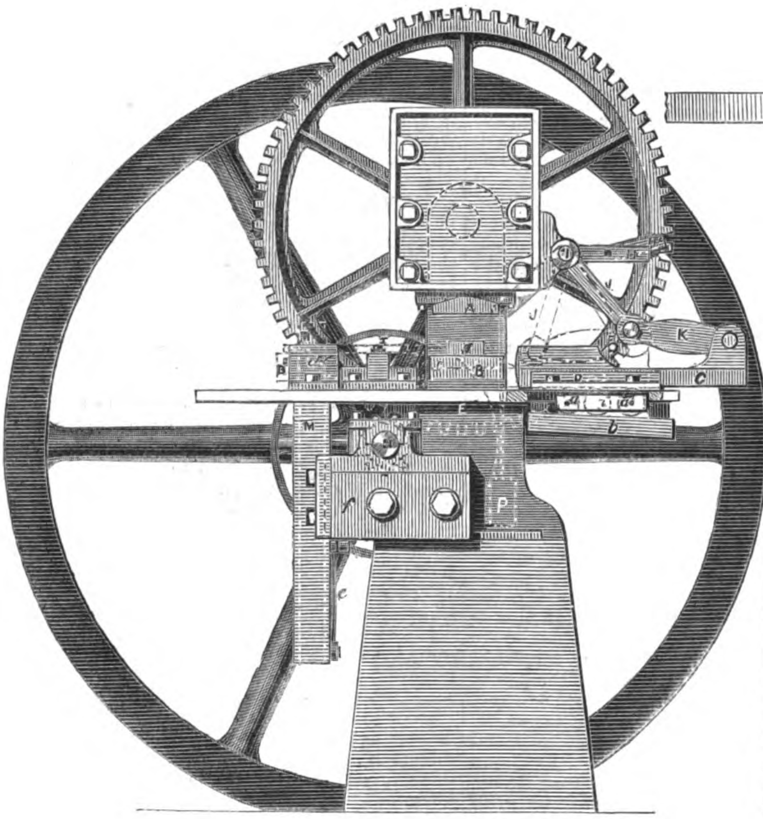


FIG. 2.

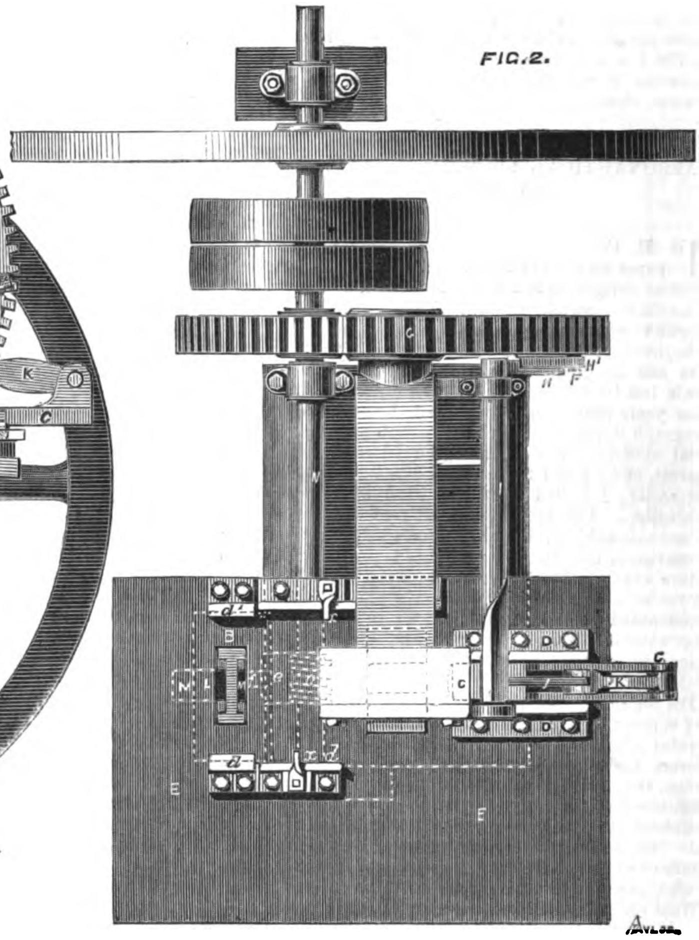


IMPROVEMENTS IN BRICK-MAKING MACHINERY.

SOME improvements in brick-making machinery have recently been patented by Mr. P. Hooker, of Pump-row, Old-street-road, and are illustrated in the accompanying engravings. Fig. 1 represents an elevation in front view of a brick-pressing machine arranged according to his invention, fig. 2 being a plan of the same. A is a plunger adapted to an ordinary punching machine, and serving to compress the material to form the brick in the mould B on the table E of the machine, this plunger being operated in a similar manner to that of a punching press.

The improvements consist, first, in providing a slide C at one side of the table E for removing the mould from under the plunger A after compressing the material contained. This slide C works in guides D fixed on the table E, and may either be worked by means of a hand lever and connecting rod, or operated directly by the gearing working the plunger. For this purpose there is a projecting tappet F on the spur wheel G, which is brought into contact at each revolution of the wheel with a part H 1 of lever H keyed to one end of a horizontal shaft I. The other end of the shaft I carries a second lever J connected to the slide C by a rod K, and in this manner the slide C will be brought forward each time the tappet F comes in contact with and depresses lever H, which takes place after each descent of the plunger A into the mould. The latch H 1 is hinged to the lever H, so that should the machine be accidentally driven in the backward direction, the tappet F will raise and pass the latch H 1 without operating the slide C, and thus prevent injury to the machine.

The slide C is returned to the position shown by its own gravity, aided if required by a counterbalance weight P suspended from a lever arm carried on the shaft I. The motion of the slide C is further assisted by mounting it on friction rollers a and a^1 of unequal diameter, connected together by a frame i, and resting upon an inclined grating or support b fixed to the under side of the table E of the apparatus, the smaller roller a being in advance, so that when the lever H is released from the tappet F, the slide C will run back down the incline by the aid of the friction rollers in readiness for acting on the next mould which it pushes forward as before to the point of delivery after a brick has been compressed therein by the plunger A. The grating b is provided so that the dust or other matters from the table E may fall through, which would otherwise check the action of the slide C.

In order to remove the compressed brick from the mould B the latter is brought by the slide C to the position shown in dotted lines over an aperture L in the table E at the opposite side of the apparatus, the edge of the mould passing under clamps d fixed on the table so as to keep the mould firmly down on the table E when removing the brick therefrom. The brick is removed from the mould by a vertical follower M sliding on guides below the table E, which rises through the aperture L and through the mould, carrying with it the compressed brick, which is thus raised completely out of the mould. This follower M is operated by a shaft N carrying a pinion N 1 gearing with the spur wheel G, and provided with endless screw gearing O, communicating with the follower M by means of a connecting rod e and crank pin f, arranged so that after the descent of the plunger A for compressing a brick in the mould placed beneath it, the follower will rise and remove the compressed brick from the mould previously brought over the aperture L by the slide C. The brick is removed from the top of the follower M in the position shown in dotted lines in fig. 1, either directly by hand or by the mechanical arrangement already described, as being operated by the machine for removing the brick on to the platform or table raised above table E, from which it is removed by hand or otherwise. The follower M then returns to the position below table E as seen, to permit of the removal of the mould.

The action of the machine is as follows:—A mould B having been filled with the material of which the bricks are to be made, a metal block g exactly corresponding in size to the aperture of the mould is placed on the material, and the mould then brought by hand under the plunger A of the machine, which on its descent will force the block g into the mould, and thus compress the material contained into a brick of the form and dimensions desired. By employing blocks of different thicknesses the thickness of the brick may be varied, the block employed thus forming a gauge for the same. The mould B is moved from under the plunger between guides d by the forward motion of slide C, and brought to the position shown in dotted lines at B 1 and another mould having been similarly acted on by the plunger, the whole are moved forward together by slide C, and brought successively over aperture L in the table E, as at B 2. The first mould having arrived over aperture L and under the clamps d, the brick is raised therefrom by the follower M, from which it is conveyed on to the raised platform by the arrangement already described. Another brick having in the meantime been similarly compressed beneath the plunger A, the next mould is moved under the clamps d by the slide C displacing the first mould which is now empty. A small scraper x is fixed above the table E in a line with each clamp d to remove any sand or grit which may lodge on the edges of the moulds; m is the inclined shoot, placed under the aperture L to carry off any dust or matters from table E, brought to that point by moulds.

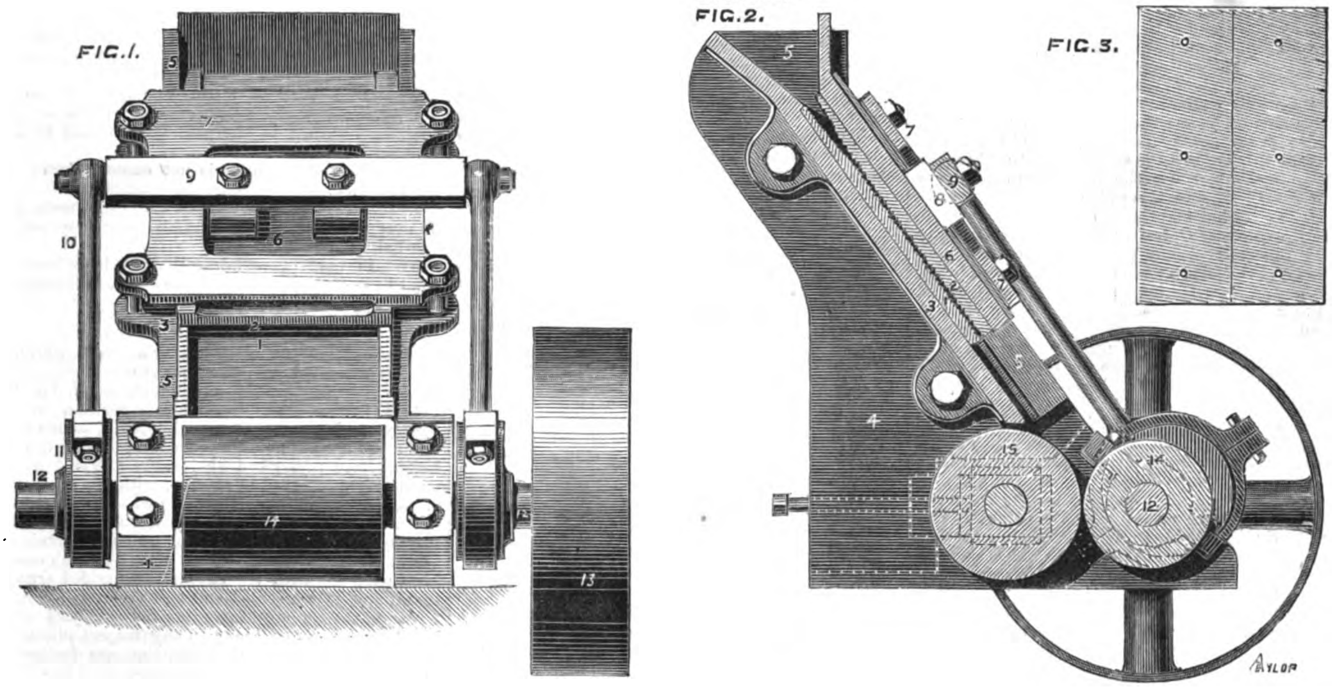
INSTITUTION OF MECHANICAL ENGINEERS.

THE annual congress of the Institution of Mechanical Engineers was opened on Tuesday in the Theatre of the Literary and Philosophical Society of Newcastle, under the presidency of Sir W. J. Armstrong, C.B. There was a large attendance of representatives from all parts of the country. Papers have been read on the hydraulic swing bridge over the Ouse, by Sir W. J. Armstrong; the mechanical ventilation of mines, by Mr. William Cochrane, of Elswick; and mechanical firing of steam boilers, by Mr. John Daglish, of Seaham. Excursions have been made to Seaton Delaval Colliery; to sea, on board the "Duchess of Sutherland," a handsome new paddle steamship, built by Messrs. A. Lesslie and Co., of Hebburn, for the London and North-Western Railway Company, to trade between Holyhead and Dublin, her engines from the works of Messrs. R. Stephenson and Co.; and to Ryhope Colliery, near Sunderland. Reports of these papers will appear in due course.

APPARATUS FOR GRINDING GRAIN.

BY MR. J. NORMAN.

FIG. 1. FIG. 2. FIG. 3.



APPARATUS FOR GRINDING GRAIN.

MR. JOHN NORMAN, of Glasgow, has patented an invention for grinding or reducing grain by means of apparatus of a simple and inexpensive character, and which may be worked by hand, or adapted to any amount of power. The apparatus comprises two serrated plates, between which the grain passes. One plate has imparted to it a short rapid reciprocating stroke. In our engraving, fig. 1 is a front elevation of the machine, and fig. 2 is a vertical section at right angles to fig. 1, whilst fig. 3 is a face view of one of the serrated plates. The serrated plates 1 and 2 are placed in an inclined position, one of them being fixed to a cast-iron bed, plate 3, which is bolted to two side standards 4, and combines with these standards to form the framing of the machine. The bedplate is formed with cheeks 5 at the sides, which serve as guides to an upper moving frame plate 6, to the under side of which is fixed the upper moving serrated plate 2. The plate 6 is kept down by a cover plate 7, which is fixed to the bedplate by screw bolts, by which its distance from the bedplate can be nicely and easily adjusted. It is adjusted so that the upper serrated plate 2 can move slightly away from the fixed one 1 when rising.

The cover plate 7 is in the form of an open frame, and through the opening in it snugs 8 formed on the moving plate 6 project, to have fixed to them a crossbar 9, by means of which the plate 6 is actuated. The ends of the crossbar 9 have jointed upon them the ends of connecting rods 10 from eccentrics 11 on a shaft 12, carried in bearings in the lower part of the standards 4, and fitted with a pulley 13 to receive a driving belt. By these means the upper serrated plate 2 is made to reciprocate rapidly over the fixed plate 1, and this action grinds or reduces the grain as it gradually passes down between them. The serrated plates 1 and 2 are tapered at their upper parts so as to be sufficiently wide apart for the grain to enter easily, and the space between them becomes gradually narrower from their upper ends downwards. The upper parts of the bedplate and upper plate 6 are shaped so as together to form a kind of hopper mouth to receive the grain from a duct or funnel, and lead it in between the serrated plates 1 and 2.

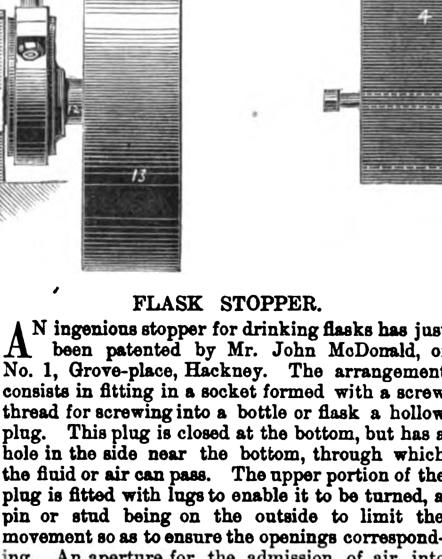
The serrations are in lines, inclined across the plates, as shown in fig. 3, and when the plates are in position, the upper ends of the serration lines of one are at the right-hand side, and those of the other at the left-hand side, so that the lines cross. The serrations are made with a downward set on both plates, that is with the lines that bisect the projecting angles inclined towards the lower end of the plates. Two smooth rollers 14 and 15 are arranged below the grinding plates (one being on the shaft 13) to receive the reduced grain or meal as it falls from them, and to crush and equalize it, and this addition will be more particularly advantageous in the case of small machines to be worked by hand, and designed for domestic use.

FLASK STOPPER.

AN ingenious stopper for drinking flasks has just been patented by Mr. John McDonald, of No. 1, Grove-place, Hackney. The arrangement consists in fitting in a socket formed with a screw thread for screwing into a bottle or flask a hollow plug. This plug is closed at the bottom, but has a hole in the side near the bottom, through which the fluid or air can pass. The upper portion of the plug is fitted with lugs to enable it to be turned, a pin or stud being on the outside to limit the movement so as to ensure the openings corresponding. An aperture for the admission of air into the bottle is formed on the outside of the plug; this aperture coincides with a small hole in the socket, so that, when the plug is turned and the vessel tilted, air enters through the aperture, and the fluid is free to run out.

In the accompanying engraving, fig. 1 is an

FIG. 3. FIG. 1. FIG. 4. FIG. 2. FIG. 5.



elevation of a drinking flask with a stopper in the mouth, and made according to this invention. *a a* is a socket which is formed with a screw thread *b* on its exterior for screwing into the neck of the flask *c*. Inside the socket *a* is a hollow plug *d*, which is closed at the bottom and has a hole *e* at its side, through which the fluid passes. The upper portion of the plug is fitted with lugs or finger pieces *f f* to enable the plug to be turned by hand. There is a stud or stop pin *g* on the outside of the plug for limiting the extent to which the plug may be moved. It rides in a recess cut in the top edge of the socket, and comes against the end of its rim. At some portion of the socket is a hole *h* which, when the plug is turned into the position for allowing the fluid to flow out, is in communication with a groove cut vertically on the plug to admit air into the flask, and so allow of the fluid flowing freely. A square is formed on the bottom of the plug, over which a washer is placed, and is held firmly thereon by means of a nut *j*. In order to prevent any fluid escaping up through the bottom of the plug, or between the plug and socket, a cap *k* is screwed on to the bottom of the socket, by which means all leakage is prevented. The socket has a hole *l* in it which, when the hole in the plug is brought round to correspond, forms a free passage to the interior of the flask. When the flask is full of fluid, and it is necessary to remove some of it, the plug must be turned a sufficient distance to bring the holes in a line to form the passage, and the flask tilted, when the fluid will run out. The top edge of the plug is rounded off so as not to cut the mouth of the person drinking from it. The plug and parts connected with it are shown in the detached views, figs. 2, 3, 4, and 5, and need no further description.

PATENT LAW FOR THE DOMINION OF CANADA.

(Concluded from page 80).

20. SIMILARLY, whenever by any mistake, accident, or inadvertence, and without any wilful intent to defraud or mislead the public, a patentee has made his specification too broad; claiming more than that of which he, or the party through whom he claims, was the first inventor or discoverer, or has in the specification claimed that he or the party through whom he claims was the first inventor or discoverer of any material or substantial part of the invention or discovery patented, of which he was not the first inventor or discoverer, and had no legal right thereto; the patentee may, on payment of the fee hereinafter provided, make disclaimer of such parts as he shall not claim to hold by virtue of the patent or the assignment thereof; such disclaimer shall be in writing, and in duplicate, and attested in the manner hereinbefore prescribed for a patent, one copy to be filed and recorded in the office of the Commissioner, the other copy to be attached to the patent and made a part thereof by reference, and such disclaimer shall thereafter be taken and considered as part of the original specification. Such disclaimer shall not affect any action pending at the time of its being made, except in so far as may relate to the question of unreasonable neglect or delay in making it. In case of the death of the original patentee, or of his having assigned the patent, a like right shall vest in his assigns or legal representatives respectively, any of whom may make disclaimer. The patent shall thereafter be deemed good and valid for so much of the invention or discovery as is truly the disclaimant's own, and not disclaimed, provided it be a material and substantial part of the invention or discovery, and definitely distinguished from other parts claimed

without right; and the disclaimant shall be entitled to maintain a suit for such part accordingly.

ASSIGNMENT AND INFRINGEMENT OF PATENTS.

21. The Government of Canada may always use any patented invention or discovery, paying to the patentee such sum as the Commissioner may report to be a reasonable compensation for the use thereof.

22. Every patent for an invention or discovery, whensoever issued, shall be assignable in law either as to the whole interest or as to any part thereof, by any instrument in writing; but such assignment, and also every grant and conveyance of any exclusive right to make and use and to grant to others the right to make and use the invention or discovery patented within and throughout the dominion of Canada, or within and throughout any one or more of the Provinces of Ontario, Quebec, Nova Scotia or New Brunswick, or any part of any of such provinces or of the dominion, shall be registered in the office of the Commissioner; and every assignment affecting a patent for invention or discovery shall be deemed null and void against any subsequent assignee unless such instrument is registered as hereinbefore prescribed, before the registering of the instrument under which such subsequent assignee may claim.

23. Every person who, without the consent in writing of the patentee, makes, constructs, or puts in practice any invention or discovery for which a patent has been obtained under this Act, or procures such invention or discovery from any person not authorized to make or use it by the patentee, and uses it, shall be liable to the patentee in an action of damages for so doing; and the judgment shall be enforced, and the damages and costs as may be adjudged shall be recovered in like manner as in other cases in the court in which the action is brought.

24. An action for the infringement of a patent may be brought before any Court of Record having jurisdiction to the amount of damages asked for, and having its sittings within the province in which the infringement is said to have taken place, and being at the same time of the courts of such jurisdiction within such province the one of which the place of holding is nearest to the place of residence or of business of the defendant; and such court, shall decide the case and determine as to cost. In any action for the infringement of a patent, the court, if sitting, or any judge thereof in chambers if the court be not sitting, may, on the application of plaintiff or defendant respectively, make such order for an injunction, restraining the opposite party from further use, manufacture, or sale of the subject matter of the patent, and for his punishment in the event of disobedience to such order, or for inspection or account, and respecting the same and the proceedings in the action, as the court or judge may see fit; but from such order an appeal shall lie under the same circumstances and to the same court as from other judgments or orders of the court in which the order was made.

25. Whenever the plaintiff fails to sustain his action, because his specification and claim embrace more than that of which he was the first inventor or discoverer, and it appears that the defendant used or infringed any part of the invention or discovery justly and truly specified and claimed as new, the court may discriminate, and the judgment may be rendered accordingly.

26. The defendant in any such action may specially plead as matter of defence any fact or default which by this Act or by law would render the patent void; and the court shall take cognizance of that special pleading and of the facts connected therewith, and shall decide the case accordingly.

NULLITY, IMPEACHMENT AND VOIDANCE OF PATENTS.

27. A patent shall be void if any material allegation in the petition or declaration of the applicant be untrue, or if the specification and drawings contain more or less than is necessary for obtaining the end for which they purport to be made, such omission or addition being wilfully made for the purpose of misleading; but if it shall appear to the court that such omission or addition is simply an involuntary error, and it is proved that the patentee is entitled to the remainder of his patent *pro tanto*, the court shall render a judgment in accordance with the facts, and determine as to costs, and the patent shall be held valid for such part of the invention described, and two office copies of such judgment shall be furnished to the Patent Office by the patentee, one to be registered and to remain on record in the office, and the other to be attached to the patent and made a part of it by reference.

28. Every patent granted under this Act shall be subject and expressed to be subject to the condition that such patent and all the rights and privileges thereby granted shall cease and determine and the patent shall be null and void, at the end of three years from the date thereof, unless the patentee shall, within that period, have commenced and shall after such commencement carry on in Canada the construction or manufacture of the invention or discovery patented, in such manner that any person desiring to use it may obtain it or cause it to be made for him at a reasonable price at some manufactory or establishment for making or constructing it, in Canada, and that such patent shall be void if after the expiration of eighteen months the granting thereof the patentee or his assignee or assignees for the whole or a part of his interest in the patent, imports or causes to be imported into Canada, the invention or discovery for which the patent is granted.

29. Any person desiring to impeach any patent issued under this Act may obtain a sealed and certified copy of the patent and of the petition, declaration, drawings and specification thereunto relating, and may have the same filed in the Office of the Prothonotary or Clerk of the Superior Court for the Province of Quebec, or of the Court of Queen's Bench or Common Pleas for the Province of Ontario, or of the Supreme Court in the Province of Nova Scotia, or the Court of Queen's Bench in the Province of New Brunswick, according to the domicile elected by the patentee as aforesaid; which court shall adjudicate on the matter and decide as to costs. The patent and documents aforesaid shall then be held as of record in such court, so that a writ of "scire facias" under Seal of the Court grounded upon such record may issue for the repeal of the patent, for legal cause as aforesaid, if upon proceedings had upon the writ in accordance with the meaning of this Act the patent be adjudged to be void.

30. A certificate of the judgment voiding any patent shall, at the request of any person or party filing it to be of record in the Patent Office, be entered on the margin of the enrolment of the patent in the office of the Commissioner, and the patent shall thereupon be and be held to have been void and of no effect, unless and until the judgment be reversed on appeal as hereinafter provided.

31. The judgment declaring any patent void shall be subject to appeal to any court of appeal having appellate jurisdiction in other cases over the Court by which the same was rendered.

PATENTS ISSUED UNDER FORMER LAWS.

32. All patents issued under any Act of the legislature of the late Province of Canada, or of Nova Scotia or New Brunswick, and all patents issued for the Provinces of Ontario and Quebec under the Act of the late province of Canada, to the date of the coming into operation of the present Act, shall remain in force for the same term, and for the same extent of territory, as if the Act under which they were issued had not been repealed, but subject to the provisions of this Act in so far as applicable to them.

2. And it shall be lawful for the Commissioner, upon the application of the patentee named in any such patent, being the inventor or discoverer of the subject matter of the patent and a British subject, or a resident in any Province of Canada for upwards of a year, if the subject matter of the patent has not been known or used or with the consent of the patentee on sale in any of the other Provinces of the Dominion, to issue on a payment of the proper fees in that behalf a patent under this Act extending such provincial patent over the whole of the Dominion, subject to the provisions of the seventeenth section; but no patent so issued shall extend beyond the remainder of the same mentioned in the provincial patent.

33. All the records of the Patent Offices of the late Province of Canada, and of the Provinces of Ontario and Quebec, of Nova Scotia, and New Brunswick, shall be handed over by the officers in charge of them to the Commissioner of Patents of invention or discovery, to form part of the records of the Patent Office for the purposes of this Act.

TARIFF OF FEES.

34. The following fees shall be payable to the Commissioners before an application for any of the purposes hereinafter mentioned shall be entertained, that is to say:—

	Dollars.
On a petition for a patent for five years	20·00
On petition for extension from five to ten years	20·00
On petition for extension from ten to fifteen years	20·00
On lodging a caveat	5·00
On asking to register a judgment *pro tanto*	4·00
On asking to register an assignment	2·00
On asking to attach a disclaimer to a patent	4·00
On asking for a copy of patent with specifications	4·00
On petition to re-issue a patent after *demande*, and on petition to extend a former patent to the Dominion, the fee shall be at the rate of for every unexpired year of duration of such patent.	4·00
On office copies of documents, not above mentioned, the following charge shall be exacted:—	
For every single or first-folio of certified copy	50
For every subsequent hundred words (fractions) from and under fifty not being counted, and over fifty being counted for one hundred	25

35. For every copy of drawings the party applying shall pay such sums as the Commissioner considers a fair remuneration for time and labour expended therein by any officer of the department or person employed to perform such service.

36. The said fees shall be in full of all services performed under this Act in any such case by the Commissioner or any person employed in the Patent Office.

37. All fees received under this Act shall be paid over to the Receiver General and form part of the Consolidated Revenue Fund of Canada, except such sums as may be paid for copies of drawings when made by persons not receiving salaries in the Patent Office.

38. No fee shall be made the subject of exemption in favour of any person; and no fee once paid shall be returned to the person who paid it except:—

1. When the invention is not susceptible of being patented.

2. When the petition for patent is withdrawn, and in every such case the Commissioner may return one-half of the fee paid.

And in case of withdrawal a fresh application shall be necessary to revive the claim, as if no proceeding had taken place in the matter.

MISCELLANEOUS PROVISIONS.

39. An intending applicant for a patent who has not yet perfected his invention or discovery and is in fear of being despoiled of his idea, may file in the Patent Office a description of his invention or discovery so far, with or without plans, at his own will; and the Commissioner on reception of the fee hereinbefore prescribed shall cause the said document to be preserved in secrecy, with the exception of delivering copies of the same whenever required by the said party or by any judicial tribunal—the secrecy of the document to cease when he obtains a patent for his invention or discovery, and such document shall be called a "caveat." Provided always that if application shall be made by any other person for a patent for any invention or discovery with which such "caveat" may in any respect interfere, it shall be the duty of the Commissioner forthwith to give notice by mail to the person who has filed such "caveat," and such person shall, within three months after the date of mailing the notice, if he would avail himself of the "caveat," file his petition and take the other steps necessary in an application for patent; and if in the opinion of the Commissioner the applications are interfering, like proceedings may be had in all respects as are by this Act provided in the case of interfering applications, provided further that unless the person filing any "caveat" shall within four years from the filing thereof have made application for a patent the "caveat" shall be void.

40. The Commissioner may object to grant a patent in the following cases:—

1. When he is of opinion that the alleged invention or discovery is not patentable in law.

2. When it appears that the invention or discovery is already in the possession of the public with the consent or allowance of the inventor.

3. When it appears that the invention or discovery has been described in a book or other printed publication before the date of the application, or otherwise in the possession of the public.

4. When it appears that the invention or discovery has already been patented, except, however, when the case is one within the seventh section of this Act; or one in which the Commissioner has doubts as to whether the patentee or the applicant is the first inventor or discoverer.

41. Whenever the Commissioner objects to grant a patent as aforesaid, he shall notify the applicant to that effect and shall state the ground or reason therefor with sufficient detail to enable the applicant to answer, if he can, the objection of the Commissioner.

42. Every applicant who has failed to obtain a patent by reason of the objection of the Commissioner as aforesaid, may at any time within six months after notice thereof has been addressed to him or his agent, appeal from the decision of the Commissioner to the Governor in Council.

43. In cases of interfering applications for any patent, the same shall be submitted to the arbitration of three skilled persons, one of whom shall be chosen by each of the applicants, and the third person shall be chosen by the Commissioner, or by his deputy or the person appointed to perform the duty of that office:—And the decision or award of such arbitrators, or any two of them, delivered to the Commissioner in writing, and subscribed by them, or any two of them, shall be final as far as respects the granting of the patent.

2. If either of the applicants refuses or fails to choose an arbitrator, when required so to do by the Commissioner, the patent shall issue to the opposite party:—and when there are more than two interfering applicants, and the parties applying do not all unite in appointing three arbitrators, the Commissioner or his deputy, or person appointed to perform the duty of that office, may appoint the three arbitrators for the purposes aforesaid.

44. All specifications, drawings, models, disclaimers, judgments and other papers, except "caveat," shall be open to the inspection of the public at the Patent Office, under such regulations as may be adopted in that behalf.

45. Clerical errors happening in the framing or copying of any instrument of the Patent Office, shall not be construed as invalidating the same, but when

discovered they may be corrected under the authority of the Commissioner.

46. In case any letters patent shall be destroyed or lost, others of the like tenor, date, and effect may be issued in lieu thereof, on the party paying the fees hereinbefore prescribed for office copies of documents.

47. No letters patent shall extend to prevent the use of any invention or discovery in any foreign ship or vessel, where such invention or discovery is not so used for the manufacture of any goods to be vended within or exported from Canada.

48. Every person who before the issuing of a patent has purchased, constructed, or acquired any invention or discovery for which a patent has been obtained under this Act, shall have the right of using and vending to others, the specific art, machine, manufacture or composition of matter patented, so purchased, constructed or acquired before the issue of the patent therefor, without being liable to the patentee or his representatives for so doing; but the patent shall not be held invalid as regards other persons by reason of such purchase, construction, or acquisition or use of the invention or discovery by the person first aforesaid, or by those to whom he may have sold the same, unless the same was purchased, constructed or acquired or used for a longer period than one year before the application for a patent therefor.

49. Every patentee under this Act shall stamp or engrave on each patented article sold or offered for sale by him, the year of the date of the patent applying to such article, thus,—"Patented, 1869," or as the case may be; and any such patentee selling or offering for sale any such patented article not so marked shall be liable to the punishment of a fine not to exceed one hundred dollars, and in default of the payment of such fine, to imprisonment not to exceed two months.

50. Whosoever writes, paints, prints, moulds, casts, carves, engraves, stamps or otherwise marks upon anything made or sold by him, and for sole making or selling of which he is not the patentee, the name or any imitation of the name of any patentee for the sole making or selling of such thing, without the consent of such patentee, or without the consent of the patentee, writes, paints, prints, moulds, casts, carves, engraves, stamps or otherwise marks upon anything not purchased from the patentee the words, "Patent," "Letters Patent," "Queen's Patent," "Patented," or any word or words of like import, with the intent of counterfeiting or imitating the stamp, mark or device of the patentee, or of deceiving the public and inducing them to believe that the thing in question was made or sold by or with the consent of the patentee, shall be deemed to have committed a misdemeanor, and shall on conviction be punished therefor by fine or by imprisonment, or both, in the discretion of the court before which the conviction shall be had; but the fine shall not exceed two hundred dollars, nor shall the imprisonment exceed three months.

51. Any person wilfully making or causing to be made any false entry in any register or book, or any false or altered copy of any document relating to the purposes of this Act, or who shall produce or tender any such false or altered document knowing the same to be such, shall be guilty of a misdemeanor, and shall be punished by fine and imprisonment accordingly.

52. Chapter thirty-four of the Consolidated Statutes of the late Province of Canada, respecting Patents for Inventions, Chapter one hundred and seventeen of the Revised Statutes of Nova Scotia (third series), Chapter one hundred and eighteen of the Revised Statutes of New Brunswick, and any Act amending any of the said Chapters, or any other Act, are hereby repealed, in so far as they or any of them may be inconsistent with this Act, or make any provision in any matter provided for by this Act, except only as respects all rights acquired and penalties or liabilities incurred under the said laws, or any of them, before the coming into force of this Act.

53. When citing this Act, it shall be sufficient to call it "The Patent Act of 1869."

54. This Act shall commence and take effect on the first day of July, 1869.

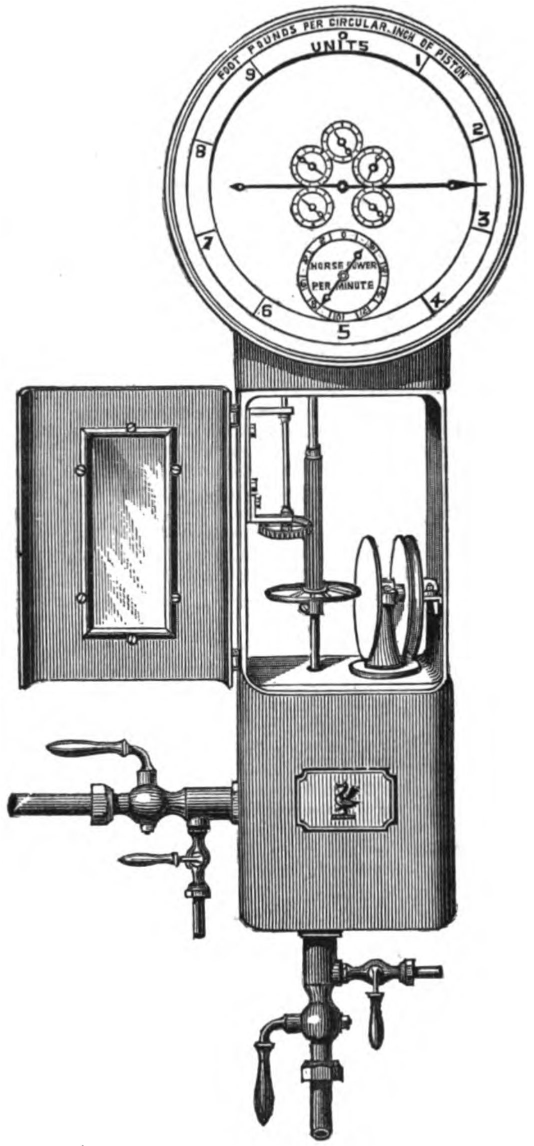
THE estimate of the sum required in the year ending March 31, 1870, to defray the salaries and expenses of the telegraph service is £90,000. This amount is required to provide for the expenses of the above service, exclusive of the interest on the purchase money, from January 1 to March 31, 1870. The revenue for the same period is estimated at £168,000.

THE number of visitors to the South Kensington Museum during the week ending July 31, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 11,074; Meyrick and other galleries, 2,725; on Wednesday, Thursday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,967; Meyrick and other galleries, 188; total, 16,854. Average of corresponding week in former years, 12,298. Total from opening of Museum, 8,658,291.

CONTINUOUS INDICATOR.

BY MESSRS. ASHTON AND STOREY.

THIS ingenious instrument was exhibited at the late Manchester Show, by Messrs. Storey and Sons, of 24, Deansgate, Manchester. It was to be seen at work at Mr. Weighell's stand, as mentioned by us in another place. It is a steam power meter and continuous indicator, its use being to determine the amount of work done by an engine in any given time. Our engraving shows an elevation of the apparatus. In the lower part is placed a piston and a cylinder, working just as an ordinary indicator. The piston rod actuates a disc wheel, which slides against the face of a vertical rotating disc; both of these are shown in the cut. The horizontal disc actuates a train of mechanism, by which a hand is moved over a dial. When the indicator has no pressure on it, the horizontal wheel being opposite the centre of the vertical disc, has no motion imparted to it, but the moment the piston rises under the influence of pressure, or falls under that of vacuum, the horizontal wheel has motion imparted to it, and it will move the further in a given time the greater the distance it is removed from the centre of the vertical disc; but this distance is determined by the pressure in the cylinder. The hand actuated by the horizontal wheel records foot-pounds per minute, per hour, &c.; and, consequently, the greater the pressure in the cylinder the greater will be the travel of the horizontal disc, and the larger the number of revolutions made in a given time, and the larger the number of foot-pounds registered. The machine shows almost at a glance the power developed during each day or each hour, while diagrams can be taken, as with the ordinary indicator.



TARGET PRACTICE AT THE BERKSHIRE VOLUNTEER ENCAMPMENT.

ON Saturday, July 31st, a very interesting competition took place in the presence of Major Sir C. S. Paul Hunter, Bart., between Corporal Bambridge and fourteen picked men of the battalion, using long Enfield rifles, and three men using the Soper direct-action breech-loader. The targets were similar to those used for file firing, but only half the usual size. Distance 200yds. Time three minutes, each party to fire as rapidly as they pleased. The scores were as follows:—

ENFIELD RIFLES.

	Points.
First squad of five men	84
Second " "	94
Third " "	94
Total	272

SOPER'S BREECH-LOADER.

Sergeant Soper	140
Private Warrick	138
Sergeant Gostage	110
Total	388

Majority in favour of breech-loader, 116 points.

It will thus be seen that two men with the breech-loader scored six points more than the fifteen men with the Enfield, Private Warrick having fired eighteen shots the first minute, twenty-one the second, and seventeen the third, making a total of fifty-six shots in the three minutes; and Sergeant Soper having scored five bull's eyes before a single shot was got off by the squad opposed to him.

ROYAL POLYTECHNIC INSTITUTION.

LAST Tuesday, the half-yearly general meeting of the shareholders took place at the institution, Regent-street; the Rev. J. B. Owen in the chair. The report showed the receipts for the half-year to be as follows:—Visitors at 1s., £4,059 15s.; workmen and children, at 6d., £690 2s. 6d.; reserved seats, £602 2s.; diving bell, £11 7s.; sale of programmes, £33 2s.; students' tickets £13 2s. 6d.; annual tickets, £4 4s.; rent receivable, £423 1s. 4d.; interest, £116 13s. 4d.; making a total of £5,953 9s. 8d. The expenses had been £5,009 14s. 6d., leaving a balance of £943 15s. 2d. The report stated that the fact of the balance of the revenue account being unusually high enabled the directors to recommend a dividend of 5 per cent. for the half-year, being at the rate of 10 per cent per annum. The report was adopted *nem. con.*, as were also the reports of Mr. Pepper, the managing director; the Rev. Charles Mackenzie, hon. manager of the educational department; and the chairman's report of the general state of the affairs of the institution. Votes of thanks were duly accorded to the chairman and various officers connected with the establishment, and the proceedings closed.

Legal Intelligence.

VICE-CHANCELLOR'S COURT.

AUGUST 3 and 4.

(Before Vice-Chancellor Sir R. MALINS.)

THE CAPTIVE BALLOON.

CROMWELL *v.* YON.

THIS was a motion to restrain the inflation and exhibition of the "Captive Balloon," on the ground of danger and annoyance from the weight of cable and ballast, the obstruction of light, and nuisance of overhanging the adjoining premises. The plaintiff is the Principal of St. Mark's College, in the immediate vicinity.

Mr. Glasse, Q.C., and Mr. Lea, appeared in support of the motion; Mr. Renshaw for the defendant.

After some discussion, the Vice-Chancellor directed the motion to stand over for a day in order

that some arrangement might be come to or undertaking given.

On the following morning, Mr. Glasse, Q.C., and Mr. Lea renewed the motion. St. Mark's College is situated across the road south of the circus, at a distance of 30ft., and, as the defendant's allege, 50 yards from the plaintiff's house, whose establishment consists of upwards of 700 pupils. The bill asked for a mandatory injunction, but this was not insisted on. The chief ground for the motion was the danger and annoyance (the cable being of the length of 2,000ft., and weighing two tons besides ballast), and the risk of explosion, it having once escaped, as is well known. On that occasion the bill was on the eve of being filed, and notice was given; but the exhibitions being continued, this bill was filed and motion made. There was a good deal of evidence of persons in the immediate neighbourhood, those on the plaintiff's part deposing to the propinquity of the rope to the chimneys and house, and the overhanging of the machine itself, causing dread and annoyance by the obstruction of light and air, and the danger of explosion when awaiting passengers, and the nuisance of the crowds collected. On the other hand, the defendant's evidence was that the balloon had, in fact, never been over the plaintiff's premises. The balloon and apparatus had cost £14,000 and upwards.

After some discussion as to the necessity of the case being heard before the vacation, it was eventually postponed till Michaelmas Term.

Obituary.

WE regret to record the death of Joseph Beete Jukes, M.A., F.R.S., Director of Her Majesty's Geological Survey of Ireland, and Professor of Geology to the Royal College of Science. Professor Jukes was born on the 10th of October, 1811, and died on the 29th ultimo. He was educated at the Free Grammar School at Wolverhampton, and at King Edward VI.'s School, Birmingham, whence he proceeded to St. John's College, Cambridge, where he took his B.A. degree in 1836. In 1839 he was appointed Geological Surveyor of the colony of Newfoundland, and returned to England in 1840. In January, 1842, he was appointed by the Admiralty naturalist to H.M.S "Fly," then about to proceed on a surveying and exploring voyage to the shores of Australia and New Guinea. In September, 1846, he was appointed to a post on the Geological Survey of the United Kingdom, under the late Sir H. D. de la Beche, the Director-General. In November, 1850, he was transferred to Ireland, as local director of that branch of the survey, and on the establishment of scientific lectureships in the Museum of Irish Industry, under Sir Robert Kane, M.D., in 1854, he was also appointed Lecturer on Geology to that institution. He is the author of many useful geological works.

Correspondence.

THE NEW CANADIAN PATENT LAW.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Copies of the new patent law for the Dominion of Canada have recently been received in this country, but none have yet reached the Patent Office in Southampton-buildings. I am glad, therefore, to see that you are printing the text of it for the information of your readers. This new law was approved by the Governor-General of Canada on the 22nd of last June, and came into operation almost immediately, viz., on the 1st of July.

The last patent law of Canada (1859) differed much from those existing in our other colonies, and was considered by most Canadians a disgrace to their statute book. It was framed purposely to prevent Englishmen or Americans obtaining patents in that country, and it enabled Canadians to pick the brains of all English and American patentees, without leaving them a chance of self-preservation. The practical effect of this law has been to entirely exclude non-resident Englishmen from the patent roll of Canada.

As for Americans, a recent writer observes that "a large number of patents taken out in Canada are the inventions of American citizens, who, on finding that patent rights cannot be obtained in their own name, on account of their being aliens, secure the services of some weak or immoral minded Canadian, who, for a consideration, makes the affirmation that the invention or discovery is his, and thus secures the patent."

The law which has just been abolished, however, permitted in a roundabout way the introduction of patents of importation. It enacted that any Canadian or British subject, being a resident in Canada, who, during his or her travels in any foreign country (*Great Britain and the United States excepted*), might become acquainted with any invention not known or in use in Canada, might on his or her return home obtain a patent for the same as the first introducer of the invention or discovery into Canada, which patent would have the same effect as if the applicant were the actual inventor, and, moreover, it could be assigned. By this curious mode of procedure, some few aliens have secured patent rights in Canada.

For many years Englishmen and Americans have been looking forward to the abolition of this disgraceful law, and the substitution of one more in accordance with the patent laws of other countries and the spirit of the nineteenth century. With what feelings of disgust, then, will they read the clauses of that which has recently passed the Canadian Parliament.

In the annual report of the Minister of Agriculture to the Governor-General of Canada for 1864, he alludes to the contemplated alteration of the patent law, in the following words:—"Of all the modifications which have been discussed for some time past, the most important are undoubtedly those which would have the effect of assimilating our laws more closely to those of the nations now at the head of civilization, and permit inventors from all countries to enjoy amongst us that protection which is now afforded them almost everywhere. The expediency and advantages of such a measure have frequently been debated. I think that the reasons given, and which seem to suggest themselves the first from a simple examination of the question, militate strongly in favour of a more liberal system than that which is possible under the present law." And, again, "I deem it unnecessary to dwell any further upon the necessity of following, in the matter of patents for inventions, the example of liberality and of reciprocity afforded us in this respect by older countries more advanced than ourselves in the development of the various branches of manufacturing industry—a course, the adoption of which it would seem they have never had reason to regret." Yet, in the face of these remarks, we find that by clause 6 it is now enacted that every alien must take up his abode in Canada for a full period of twelve months before he can apply for a patent, and the provision for "patents of importation" is entirely struck out. Under the old law, an Englishman might have applied for a patent the day after he landed in the country, but now a twelve months' previous residence is required. This is the one great defect of the new law. There are other points of much importance, but which I have not time to point out here.

Fortunately for English inventors, this new law requires the approval of the Home Government before its provisions become binding, but as only six months are allowed for examination and ratification here, it is necessary that immediate action be taken to bring the matter before the notice of the Colonial Office. There are two public bodies whose duty is to take the initiative in this matter, The Commissioners of Patents and The Inventors' Institute; and I ask also your assistance, and that of the scientific press of the day, to prevent that which would prove a great injustice to all inventors outside Canada, and would re-act on Canada herself as a material bar to her onward progress.—I am, Sir, yours, &c.,

Blackheath, S.E., August 2. JOHN FORDRED.

STEERING GEAR.

SIR,—My attention has been drawn to the letter of your correspondent "M." on steering apparatus, in your magazine of the 30th ult. After an expression of the great want of a perfect steering apparatus for merchant vessels as well as for ships of war, he briefly alludes to three patented inventions for steering ships, mine being the first one of these.

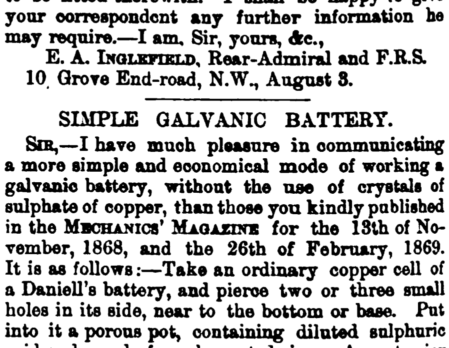
Your correspondent complains that though such inventions are sometimes tried by the Government, the public have no knowledge of the results. My invention, which has been lately fitted to one of the largest of her Majesty's ironclad frigates—the "Achilles"—was reported upon officially after trial to the Board of Admiralty. This report, being official, is retained for official use. It stated that the chief points of advantage were—1. Sufficient motive power always available. 2. The steadiness with which the power applied overcomes the resistance of the rudder at the highest rate of speed, especially when the helm is nearly hard over. 3. The security with which the rudder is held at any desired point. 4. The readiness with which the rudder is freed after being hard over, and thereby allowed to right itself rapidly when going at speed. 5. The ease with which the power is applied, one man being able to use it under any circumstances. 6. The facility with which the tiller is connected and disconnected from the hydraulic rams.

The only defects pointed out have been for the most part remedied. For a fuller description, I would refer "M." to an article in the "United Service Gazette," of June 26, which explains the form and action of my hydrostatic steering gear, and this I may supplement by saying that my steering apparatus may be kept continually in gear, and by its use one man is capable of doing what twenty men have never accomplished in the case of the "Achilles," viz., to put the helm hard down when proceeding at full speed. I desire nothing more than to test this apparatus under the greatest disadvantages, and I will undertake to fit a simple water engine, lying on the keel of the ship, which shall be available at a moment's notice, easily worked by one man on the bridge, and capable of putting the helm hard down of the largest ship, going full speed, in less than fifteen seconds. The ship may be steered by the usual wheel and ropes on ordinary occasions, but should an emergency arise, the pilot, officer of the watch, or captain, may, from the bridge, do what, as many men as he could place at the wheel, would fail to accomplish. I have been five years perfecting my invention, and it was only fitted to the "Achilles" after their lordships had received an official report from Sir William Armstrong and Mr. Penn that they considered the plan "safe, rapid, and manageable," and recommended one of her Majesty's ships to be fitted therewith. I shall be happy to give your correspondent any further information he may require.—I am, Sir, yours, &c.,

E. A. INGLEFIELD, Rear-Admiral and F.R.S.
10 Grove End-road, N.W., August 3.

SIMPLE GALVANIC BATTERY.

SIR,—I have much pleasure in communicating a more simple and economical mode of working a galvanic battery, without the use of crystals of sulphate of copper, than those you kindly published in the MECHANICS' MAGAZINE for the 13th of November, 1868, and the 26th of February, 1869. It is as follows:—Take an ordinary copper cell of a Daniell's battery, and pierce two or three small holes in its side, near to the bottom or base. Put into it a porous pot, containing diluted sulphuric acid and a rod of amalgamated zinc. An outer jar or containing vessel is required, of the same height as the copper cell, which, when filled with the copper solution, will flow through the small holes and fill the copper cell. Another porous pot is placed in the outer jar, also containing diluted sulphuric acid and a rod of platinized graphite, silver or copper, and which forms the positive pole of the battery, the zinc rod being the negative pole The outside of the copper cylinder is electrically dissolved, and keeps up the strength of the copper solution, while the inside receives a coating of copper. I have one working at the present time The arrangement will be seen from the accompanying sketch, in which a^1 is the porous pot



containing the rod of amalgamated zinc or negative pole z; a^2 the porous pot, containing the plate of platinized silver or positive pole s; b, outer jar or containing vessel; c, copper cell; d, three small holes in copper cell.—I am, Sir, yours, &c.,

95, Cross-lane, Salford, August 2. JAMES HOWARD.

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscriber of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the Mechanics' Magazine. Letters relating to the advertising and publishing departments should be ad dressed to the publisher, Mr. R. Smiles, Mechanics' Magazine Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Naval, Military, and Gunnery Items.

The next examination of candidates for direct commissions is to be held at Chelsea Hospital on Monday, November 1, and following days.

The Belgian mitrailleuse, illustrated and described in our last issue, was undergoing trial yesterday week at the inner range, Royal Arsenal, Woolwich, under the superintendence of Major Fosbery. The object of the gun, by the rapidity of its firing and supposed destructive effect, is said to compare with that of shrapnell shell fired from field guns.

A meeting of the Military Education Commission was held on Tuesday last. Present—Lord Dufferin (chairman), Lord E. Cecil, M.P., Lord Northbrook, Sir D. Cameron, Major-General E. Wilmot, Major-General Haythorne, Dr. Butler, Mr. Lake, Mr. Parker, M.P., and Lieutenant-Colonel Chesney. The secretary, Captain J. W. Hozier, was also in attendance.

The Galway steamers "Columbia," "Hibernia," and "Anglia" have been disposed of by the liquidators of Overend, Gurney, and Co., at, it is understood, an immense depreciation from their original cost. The "Columbia" and "Anglia" have, we hear, been purchased by the Turkish Government, and the "Hibernia" is being fitted as a twin screw for telegraph purposes.

Major-General Sir W. F. Gordon, K.C.B., Inspector-General, Royal Engineers, arrived on Monday evening at Plymouth, and on Tuesday, accompanied by his aide-de-camp, Colonel Westmacott, who commands in the west, and Captain Durnford, visited the forts at Staddon, Laird, and Knackersknowie. On Wednesday they inspected the fortifications at Tregantle, Screasden, and Picklecombe.

The "Blanche," screw, built and engined by Messrs. Henderson, Coulborn, and Co., of Renfrew, for M. Frederic Mallet, of Havre, has made a trial trip under the supervision of the owner and some French engineers. The burden of the "Blanche" is 1,200 tons, and her engines are on the builders' compound principle, and of 120-horse power nominal. In her trial trip she attained an average speed of nearly 10¼ knots per hour, with a consumption of ordinary Scotch coal at the rate of 9½cwt. per hour.

A most extraordinary accident recently occurred in the Wapping Dock, Liverpool. The iron ship "Flying Venus," 1,393 tons, belonging to Mr. Edward Bates, had just discharged a Bombay cargo, and was left with nothing aboard but 120 tons of ballast. Some men were engaged about noon hauling at the ship, when the ballast suddenly shifted, and she capsized, and the hatches being open she sank into the dock. The men on board managed to scramble on shore in time to escape injury, and luckily two ships, lying near the "Flying Venus," had been removed shortly before she capsized, or the consequences might have been most disastrous.

The Belgians, anxious to return the cordial welcome given to their Garde Civique at Wimbledon, are organizing a grand international rifle contest, to take place at Liege, from the 15th to the 20th September. The programme of the fetes is a very inviting one:—International contest at short distances; official reception by the authorities; review of Garde Civique and the foreign riflemen, probably by his Majesty the King of the Belgians; musical contest open to foreign societies; grand banquet to the visitors in the Provincial Palace at Liege; balls; excursion to Spa; international shooting match at long distances at Spa, and fetes given by that city; return to Liege, and departure for Brussels for the celebration of the annual national fetes. The committee offer prizes of the total value of 20,000f., and the railway companies will make considerable reduction of fares in favour of foreign riflemen.

Miscellanea.

A new rolling mill for the production of plates, &c., is being fitted up at Alfort, near Paris. This rolling mill will be in working order in a few months.

On Monday, at a graduation ceremonial, the Senatus of the University of Edinburgh conferred the honorary degree of Doctor of Laws upon Sir Roderick Murchison.

Favourable intelligence has been received of the rising of the Nile. The inundation this year is expected to be most abundant, and all the necessary precautions have been already taken in Upper Egypt.

Captain Shaw, the chief of the Metropolitan Fire Brigade, leaves London, for New York, tomorrow, to inspect the new fire establishment recently formed in that city, as also those in Canada.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending July 31, was 3,661. Total number since the opening of the Museum, free daily (May 12, 1858), 1,612,354.

A parliamentary return gives a list of pictures presented to or purchased for the National Gallery—284 presented, 256 bequeathed, and 313 purchased. The cost of the 313 purchases, which has been spread over 45 years, has been £254,527.

Rail orders are still in course of execution in Belgium to the extent of between 190,000 and 200,000 tons, a total equivalent to about 15 or 16 months' production. The Belgium coal trade, as is usually the case at this period of the year, is somewhat dull.

Accounts from Berne state that a terrible inundation has just submerged the valley of Hasli in the Oberland, well-known to all visitors of the Hospice of the Grimsel. The Reichenbach has changed its bed, and the hotel of that name was very near being carried away by the waters.

The Missouri Pacific Railway, a road nearly 200 miles long, has just changed its line from the broad to the narrow gauge. Nearly 1,400 men were engaged in the work, and they laboured with such celerity that the task was accomplished in twelve hours, and without interrupting the business of the road.

A deplorable accident took place a week ago at Douai, involving the loss of eleven lives. At about two in the afternoon twelve workmen were being hoisted in one of the usual baskets of a coal pit called the Fosse Notre-Dame, and had reached a height of 60ft., when an earthfall took place many yards above their heads, and a block of stone striking one of the upper corners of the hoist, precipitated it with its contents to the bottom. Underneath was deep water, but only one man survived this terrible fall.

Philadelphia is to have a bigger musical jubilee than Boston has had, which was recently described by us. It is proposed to celebrate the centennial anniversary of the signing of the declaration of independence on July 4, 1876, by a gigantic musical festival, in a building especially erected in Fairmount Park, capable of accommodating 100,000 spectators and 12,000 performers. A letter has been sent to President Grant giving him the particulars of this enterprise, and asking "an expression of his kind approval, and for its success the best wishes of his patriotic heart."

It is reported that, in the course of the month of October, the frequently mooted project for an Atlantic cable from the Orkneys, via the Faroe Islands, to Quebec, will have taken definite form and be brought before the public. The cable which is to connect Thurso with the Orkneys is to be laid down immediately under the auspices of Mr. Nathaniel Holmes, of Winchester-buildings, and the Transatlantic line will be promoted by the some gentleman. It is understood that, upon its completion, it, as well as the cable across the Pentland Firth, will be taken over and managed by the Post Office.

The committee to whom the question of the sites for the new law courts was referred decided on Friday last by nine to seven on the adoption of a report recommending the Carey-street site in preference to the Embankment. The latter, it will be remembered, was not the original Embankment site, which was discarded as being too costly, but one of much more restricted area, and with no frontage to the Strand, and which, in fact, possessed none of the advantages claimed for the original proposal. The Carey-street site will, it is understood, be quite large enough for the law courts if built upon the reduced plan.

The Moselle district has been sending of late so large a quantity of minerals into Belgium and Prussia that the Eastern of France Railway has been obliged to borrow 400 trucks from a neighbouring company, the Northern of France. In the department of the Nord considerable orders for pig have been concluded of late at £2 16s. 10d. per ton; there has also been a well-sustained demand for iron, and the rail mills have been working with much activity; the Anzin Works, it is stated, have even their production engaged up to 1872. A want of labour is reported in the Nord, and one or two descriptions of iron have had to be imported in consequence.

A Government agent attended at the Palais de Justice, Paris, a few days since, to receive numbers of the "Lanterne," and other condemned publications. Of the former there were about 160,000 copies, filling 42 sacks. Formerly articles of this description were pounded in a large iron mortar, but at present the proceeding is much more simple. The agent takes the whole to a paper factory, where under his inspection they are thrown into a cauldron of boiling water and reduced to pulp, then passed under a wheel cylinder, whence the matter issues in the form of cardboard. Thus are peccant prints squashed out of existence.

A general meeting of the Royal Horticultural Society was held on Tuesday afternoon in the Council-room at South Kensington, Mr. G. F. Wilson, F.R.S., in the chair. There was an excellent show both in the fruit and floral departments. The specimens of hollyhocks were truly magnificent, and two wonderful specimens of orchid cultivation from the Bishop of Winchester were greatly admired. The greatest novelty was a curious orchid from Mr. Wilson Saunders, which was remarkable for its hispid leaves and flowers. Colonel E. T. Gourley, M.P., and Mr. Henry King were elected fellows of the society.

Mr. Horace Jones, the City architect, on behalf of the Markets Improvement Committee of the City Corporation, has submitted to the Metropolitan Board of Works a plan for utilizing the site of old Newgate-market. It is proposed to form streets on the site of the market by the erection of four blocks of buildings, divided by cross streets, one of 20ft. and the other of 30ft. in width, and surrounded by a narrow passage. The Building Act Committee, considering that by the plan proposed an improvement will be effected, recommended that the plan be approved, and the Board, under the circumstances, set aside their standing orders as to the width of new streets being of 40ft., and sanctioned the plan.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

Boilers and Furnaces—48, 64
Buildings and Building Materials—46, 78
Chemistry and Photography—42, 70
Cultivation of the Soil, including agricultural implements and machines.—37, 60, 71
Electrical Apparatus.—40
Fibrous Fabrics, including mach ineryfor treating fibre pulp, paper, &c.—52, 57, 74, 76, 80
Food and Beverages, including the apparatus for preparing food for men and animals—43, 51, 56
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c.—34, 39, 49, 58
General Machinery—61, 68, 72, 73
Lighting, Heating, and Ventilating—45, 54
Metals, including apparatus for their manufacture—53, 66, 67
Miscellaneous—38, 41, 44, 47, 62, 83
Roads and Vehicles, including railway plant and carriages, saddlery, and harness, &c.—55, 63, 69, 75, 81, 82
Ships and Boats, including their fittings—50, 77
Steam Engines—35, 59
Warfare—36, 79

34 D. Nicoll, Cornhill. *Making garments.* Dated January 5, 1869.

This consists in weaving or otherwise forming or causing to be formed a single piece of cloth, having an oval shape with an oval aperture in its centre. When the oval-shaped article has been manufactured, a garment which combines the advantages of a railway rug and a cloak may be produced therefrom by dividing one of the before-mentioned oval pieces into two equal parts, and binding the cut edges so as to produce the garment. Elastic gussets may also be inserted into the oval piece, so as to admit the neck of the wearer when the article is intended to be used as a cloak. The article will also be rendered sufficiently elastic at this part to admit of it passing round the waist, so that it may be used as a railway rug. Or the article when divided in the centre may be provided with straps either elastic or non-elastic, so that it may be secured either round the neck or the waist of the wearer, according to the purpose for which it is intended to be used. By the employment of elastic gussets, the inventor is enabled to produce an article of underclothing which will serve the purpose of two articles at present in use, viz., an under vest and drawers. The advantages of making these garments in one instead of two pieces, will be, first, a considerable saving in the cost of manufacture, and, second, the production of an article of greater comfort to the wearer. In the manufacture of ordinary over and under coats, it is proposed to employ the above-mentioned elastic gussets inserted under the arm pits, whereby

greater facilities will be afforded for putting on the garment, and more freedom of action will be given to the wearer.—Patent completed.

35 W. DAWES, Leeds. *Steam engines.* Dated January 5, 1869.

This invention chiefly relates to "equilibrium" slide valves, and consists in a novel and simplified method of preventing or reducing the pressure of steam upon such valves. It may be thus described:—Round or near the upper edges of the ordinary or any slide valve the inventor casts or constructs, when necessary, a flange or projection of any convenient size and thickness, and he fits upon or to this flange or projection, in a manner hereinafter described, a strong plate or frame, by preference also rectangular (though this is not essential), and generally a little larger than the face of the valve, planed and fitted perfectly true on one side or face to work or slide "steamtight" against the inside face or surface of the steam chest cover or other fixed plate, also made true for that purpose. The before-named plate or frame is so fitted upon or attached to the valve that it is free or elastic in a perpendicular direction to the face, but is compelled to move with the valve without shake or "play" in a lateral or longitudinal direction. Dispensing entirely with the packing rings and other loose or separate parts, the inventor now constructs an elastic metallic steamtight connection, to be inserted between the flange or projection (*i.e.*, the valve), and the before-named plate or frame, and united or jointed to each of them by screws, rivets, or otherwise, in a steamtight and permanent manner, and thus constitutes what may be called an elastic valve, virtually or practically in one piece, and of a more simple, reliable, and durable nature than heretofore.—Patent completed.

36 S. REMINGTON, Ilion, U.S.A. *Breechloaders.* Dated January 5, 1869.

This relates to a previous patent, dated December 23, 1863 (No. 3253), and January 18, 1865 (No. 152). In these former specifications, the arm is described and shown constructed only for firing metallic cartridges (either rim-fire or central-fire), but by the present invention the "Remington" arm, so called, is adapted to the firing of cartridges with cases of paper, cloth, or other soft material. The invention consists, chiefly, in combining with the swinging breech-piece of the Remington arm a needle for penetrating and igniting the cartridges. In so constructing the firing bolt or pin, which carries the needle, as to permit the needle to be driven forward when struck by the hammer far enough to ignite the cartridge, in the peculiar construction of the swinging breech-piece and hammer, and in the means for extracting the exploded cartridge cases.—Patent completed.

37 A. W. C. WILLIAMS, Bridgeport. *Lawn mowers.* (A communication). Dated January 5, 1869.

This consists in a novel manner of constructing the frame of the machine and mounting it on a roller, whereby the latter is made to have sufficient traction to drive in the most efficient manner the cutting device. The invention also consists in a novel manner of applying the handle to the frame of the machine, whereby the latter may be pushed along by the operator without at all affecting the equilibrium of the machine on its roller. The invention also consists in a novel and improved cutting device, which may be constructed at a very small cost and still be strong, durable, and not liable to spring during the operation of cutting. The invention further consists in a peculiar application of shoes to the device, whereby the height of the cut may be regulated as desired.—Patent completed.

38 J. STEVENS, Orange, U.S.A. *Plaiting machines.* Dated January 5, 1869.

This consists chiefly in the peculiar devices for giving the required form or configuration to the plaiting; in the means for delivering the linen or other fabric properly to the plaiting devices; in the construction and arrangement of apparatus for holding and adjusting the plaiting devices; in the means for creasing the plaits after they have been formed by the devices; in the combination with the same of a pair of rollers for drawing the fabric through the machine; in the peculiar action of the cutting mechanism for dividing the strips into portions of the required length; and in the means for guiding the solid strips from the draught rollers to the cutting mechanism. The invention also consists in combining together the parts of the machine in such a manner that the various operations of first delivering the fabric to the plaiting devices, then forming and creasing the plaits or folds, and finally dividing the strips into portions of the required length, are properly and expeditiously effected. The invention also consists in the means employed in combination with the above-mentioned devices for winding the strips upon the spools, and, at the same time, preparing the fabric for being worked by applying soap to its surfaces in a manner which does not cause it to shrink.—Patent completed.

39 H. L. VALLEE, H. A. DOUBLET and A. M. H. ARMAUD, Paris. *Artificial flowers, &c.* Dated January 6, 1869.

This consists in the employment of vegetable or paper parchment for the manufacture of artificial flowers and foliage. The material is cut, dyed, stiffened, gaufred, or embossed glazed, and is subjected in every respect to the same treatment as at present employed for the manufacture of the flowers and foliage in present use.—Patent abandoned.

40 J. S. GISBORNE, Liverpool. *Telegraphs.* Dated January 6, 1869.

This consists in an improved construction of crank or corner piece, to be used in place of the ordinary pulleys or L cranks. This crank is made in the form of a cross, or like the letter Z, or with radial arms, and is free to move on or with a central axle or stud. The ends of the double line of motion communicators are secured to the extremities of the crank, and by the relative position of the extremities provision is made so that the motion communicators can be led away at any desired angle. Second, in an arrangement of parts to provide for expansion and contraction of the motion communicators. For this purpose the inventor connects to and suspends from the motion communicators a compensating weight or balance. The weight or balance is connected directly to the motion communicators, or to a chain, rod, or wire provided with a "biting clutch." This part of the invention is applicable where only a single line of communication is employed.—Patent abandoned.

41 E. ROBBINS, Somers Town. *Manufacture of casts.* Dated January 6, 1869.

The inventor employs pulverized substances to ornament or decorate surfaces. The pulverized substances may be of various colours and descriptions, alone or combined with one another. In order to distribute the pulverized substances in designs or patterns upon the surface to be ornamented according to this invention, the inventor employs stencil plates, placed upon or a short distance above the surface, and, if desired, the stencil plates may be embedded in the body of the slab or other form. These stencil plates or the surface to be ornamented may, according to this invention, have movements so as to produce changing effects, and various colours or kinds of powder may be passed through the stencil plate together or successively, the supply of each of such powders being under control, so as to produce shaded or other effects. The powders to form an ornamental surface may, according to this invention, be distributed over a surface, and the cement, plaster, clay, or other material which is to be decorated, afterwards laid or run over the pulverized matter, which will adhere to the plastic substance, and form an ornamental surface. The powders when distributed may be temporarily secured, so as to prevent disturbance of the design by the application of steam or moisture, or by mixing materials with the powder, which can be rendered adhesive by heat, or they may be secured by distributing them upon an adhesive surface. When carrying the first part of this invention into practice for the decoration of surfaces formed in cement, plaster, or other substance of a similar character which has the property of "setting" or indurating when moistened with water or other liquid, alone or with chemical agents in solution, the inventor compounds the decorative pulverized colours, minerals, metals, or substances before referred to with powdered cement or plaster, or with soluble silicates, or both, or with other known substances which will indurate after the application of water alone, or having chemical agents in solution, and in some cases substances, such as powdered sulphur, which will become adhesive by the application of heat, may be mixed with the pulverized materials. The second part of the invention relates to embedding on ornamental or decorative design or figure, formed from fibrous material, threads, strings, netting, lace, or fabric of fibrous material, or wire, or formed from paper pulp or flock alone, or combined with one another or with other materials, in the surface of a slab or block of plaster, cement, or other material. When carrying this part of the invention into practice for forming a slab, he employs a table or surface, such as that hereinbefore described. The inventor then arranges upon such table or surface in any desired figure or design, fibrous material, strings, or fabric of fibrous material or wire, paper, paper pulp, or flock, alone or combined with one another, or with such other material as may be required to retain them in the required form. In some cases he employs netting or lace in fibrous materials, or wire, or a woven fabric, or paper which may be in any suitable shape, and may have a design thereon. The paper or other material may be combined with plaster or cement, so as to retain the required shape for imbedding. The string or threads or other materials may be stiffened by the application of suitable size or varnish, so as to retain a definite form, and the strings or other materials may be variously coloured. After the strings or other of the above-named materials have been arranged upon the table or surface in the desired form, cement or plaster, or other material which "sets" or hardens by the addition of water or other liquid, alone or with chemical agents in solution, is applied upon the table or surface so as to cover and imbed the materials previously laid upon such table, and the threads or other materials above named may then be allowed to set with the slab, and be incorporated therewith.—Patent completed.

42 K. WALKER, Wicklow. *Sulphuric acid.* Dated January 6, 1869.

This consists in the employment of ammonia or carbonate of ammonia to condense the nitric gases escaping from the exit of a vitriol chamber. To accomplish this, the inventor causes the ammonia or carbonate of ammonia to come in contact with the escaping fumes either in a coke tower or chamber. The fluid thus resulting is again afterwards decomposed with sulphuric acid, and the escaping nitric fumes are returned into the vitriol chamber for the decomposition of the sulphurous gases.—Patent completed.

43 A. TYLER, Mark-lane, E.C. *Bonbons.* Dated January 6, 1869.

This consists in making bonbons or cossacks in a novel and extensive manner, by which bonbons of greater commercial value and use can be made. The inventor takes, say, an ordinary bottle of champagne, wine, or other bottle of large dimensions, and encloses it in paper, either fancy or plain, coloured, or not coloured, or in silk, satin, or in any other material. This paper or material may have ribbon bound round it, to secure the bottle within it; he then fastens natural or artificial flowers, flags or banners or other emblems on the outside adhesive gum, pins, or other fastenings.—Patent completed.

44 W. PIDDING, Walcot-square. *Extracting essence from plants.* Dated January 6, 1869.

The inventor places the living plant, or whatever vegetable production he may wish to subject to the process, in a receiver or vessel so formed as to allow of the air from within being extracted as required. The plant or vegetable production under process is to remain in the receiver a sufficient time to allow of it or them giving forth or emitting their aroma or essential oil or vapour. The air in the receiver thus becomes impregnated and scented by the same. The inventor extracts the air so impregnated from the receiver by means of an exhausting apparatus, or any suitable appliance (to an extent so as not to deteriorate or injure the living plant or vegetable matter under operation) and passes the same into a suitable vessel or receiver; such receiver may contain oil, fatty, or oleaginous, saponaceous, or other appropriate matter or spirits, suitably arranged so that they may become impregnated with the scented air and vapour let into them from the first receiver.—Patent abandoned.

45 G. EVELEIGH, Bow. *Manufacture of gas.* Dated January 7, 1869.

This relates to the manufacture of gas for lighting purposes from coal, shale, wood, bitumen, petroleum, or other substances containing carbon, hydrogen or nitrogen in their chemical composition and to the purification thereof. Also to certain means of producing gas from such liquefiable substance for and applying it or impure gas otherwise obtained from the substances above mentioned to the purpose of generating heat in furnaces, or in other situations where heat is required. And to the purification of mineral oil for the purpose of rendering it non-explosive below a temperature of 300deg. Fah. The improvements in the manufacture and purification of the gas obtained from the substances referred to consist in the application of certain means for the distillation or redistillation thereof, and the reduction during that distillation or redistillation of all or any of the waste products ordinarily produced in the distillation of such gas from those substances, so as to convert the whole (or nearly the whole) of such distilled waste products into an increased quantity and improved quality of gas for lighting or heating purposes. These improvements are effected by passing the gas as soon as produced from the substances through upright tubes, cylinders, or chambers, which for convenience he calls "redistillation retorts," and of which one or more may be employed of dimensions suitable to the quantity of gas to be produced and the extent of purification required. The "redistillation retorts" are loosely filled with any one or more, as may be required, of the following or any other substances which will produce similar effects, namely, charcoal, coke, chalk, lime, bones, limestone, filings, turnings or pieces of iron, or other metal or scorious metal not charged with sulphur, or of metals somewhat oxidized, which substances the patentee for convenience calls "chemical purifiers." The "redistillation retorts" (if more than one are employed) are then connected together and to the gas generating retorts by suitable pipes, so as to allow the gas as produced to pass through them and amongst the "chemical purifiers" contained therein. They are placed in a suitable furnace and raised to a more or less red heat, according to the nature of the gas or the substance from which it is produced and the extent of purification required. The gases and waste products in passing through the heated "chemical purifiers" in the "redistillation retorts" will undergo the necessary chemical changes to produce gas of the required quality and purity, and will leave little or no residue; the quantity of gas resulting will be much increased, while the sulphur will be united to the metallic substances or calcareous earths contained in the "redistillation retorts," and can thus be removed in a dry and inoffensive state when needful. The purified gas may then be cooled by passing through pipes exposed to any ordinary cooling influence; it may then go at once to the gas holder for use.—Patent completed.

46 F. MANSERGH, Westminster. *Stench traps.* Dated January 7, 1869.

This consists of a vessel of iron, clay, or other material, to be placed outside a house or dwelling in any convenient position, for the attachment of a waste pipe or pipes leading from the sinkstone or other place. These sockets, pipes, or openings are formed in the gully, two at the top and one at the side. The opening at the side is for the purpose of attaching the gully to a pipe drain conveying the refuse of the house to the main sewer. At the same end, but at the top of the gully, is formed another opening, to which may be attached airtight an ordinary water down spout or other pipe, to act as a ventilator for the house drain, and to prevent the sewer gases from being put under pressure a diaphragm is formed across the gully and in the top part, extending the full width of the gully and below the bottom of the outlet pipe or drain, thus making an ordinary water stench trap. In the upper part of the gully, and at the side opposite the house drainpipe, is placed an open movable grating, to allow of the ingress of the surface water from the yard or place where the gully may be situated, and for the removal of any deposit which may accumulate in the bottom of the gully. At the end of the gully which is farthest from the drain, and beyond the grating, is formed a smaller vessel, trapped in a similar way to that of the lower part of the gully, with an opening or provision for attaching the waste pipe or pipes from the sinkstone or any other place.—Patent abandoned.

47 J. F. COOKE, Cannon-street. *Copying ink.* Dated January 7, 1869.

The inventor substitutes for from 20 to 50 per cent. of the quantity of water used in the manufacture of ink, the same volume of glycerine. He also substitutes for glycerine in the manufacture of this ink, sugar, treacle, or chloride of calcium in solution, in the same proportions as the glycerine.—Patent abandoned.

48 H. DAVY, Adelphi. *Feeding boilers.* Dated January 7 1869.

This consists, first, in an improved apparatus, by which water is raised to and injected into steam boilers and other vessels, which apparatus may be made to measure the water injected, and to preserve the level of the water in the boiler or vessel from varying beyond narrow limits. Second, in improved means of actuating the steam admission and emission valves of steam pumps.—Patent abandoned.

49 F. N. GISBORNE, West Strand. *Sewing machines* Dated January 7, 1869.

The inventor mounts the seat on the top of a cylinder containing water or other liquid or air. The seat is capable of rising and falling within certain limits, so that when the attendant is sitting on the seat it shall be caused to force the contents of the aforesaid cylinder gradually into a smaller cylinder having a piston working therein, on the rod of which is formed or fixed a toothed rack, which takes into a pinion mounted on a shaft or axis, and giving motion to suitable multiplying gear, so as to obtain the desired speed to the driving pulley, wheel or drum giving motion to the driving shaft of the sewing or other machine.—Patent abandoned.

50 F. R. A. GLOVER, Bury-street, W. *Fishing anchors* Dated January 7, 1869.

The first improvement relates to the apparatus for letting down the anchors in such a manner that the point of the palm may be made to strike the ground, so that it will enter at once and hold firmly. It consists in adapting to one of the arms of the anchor a sliding ring and a coupling hook which lies snugly under the palm. The point or end of this hook is made with a hole or eye, which is passed through one of the links or the shackle of the chain cable, and is secured there temporarily by means of a cross pin which is passed through the eye in the hook and is suspended by a cord or short chain, which is hung loosely from the hawse bit of the hawse hole, so that the pin may be withdrawn when required, when the anchor is suspended in a proper position ready for lowering. The pin with its cord or chain will then be plumb with the hawse hole, and as the anchor descends, the pin will be drawn out and left hanging behind; when the anchor reaches the ground the lowermost palm will strike the ground and enter. The chain cable will be loosened when the anchor strikes, and will fall away from the hook, and

thus leave the cable free to haul on the stock of the anchor, in the usual manner. The cable is provided as usual with a roller and stopper, a shackle link, a swivel link, and a coupling link. The other improvement relates to a novel device for weighing the anchor when the palm has become fixed in a cleft of rock at the bottom. The withdrawal of the palm is effected by adapting to the ring on the arm a small chain cable, with a few very strong links at the end nearest the anchor. This small cable may be buoyed so that if it should not prove strong enough to haul up the anchor, an additional and stronger cable provided with a ring and grab link which will pass over, the small cable may be sent down the latter, until the grab link reaches strong links at the end of the small cable. Then by hauling on the extra cable, the grab link will tightly hold on to the strong piece of cable below, and will allow of sufficient power being put on to extricate the palm from the cleft in the rock and to haul up the anchor.—Patent completed.

51 J. H. JOHNSON, Lincoln's Inn-fields. *Concentrated food tablets.* (A communication). Dated January 7, 1869.

This consists in combining together in the form of a tablet or cake the four different descriptions of food, namely, the concentrated essence or juice of flesh meat, the concentrated essence or juice of poultry, game, or other birds, the concentrated juice or extract of vegetables, or, in some cases, the vegetables themselves, and some feculent or amylaceous substance or substances, such for example, as rice, vermicelli, tapioca, and the like. By this combination of substances, food tablets or cakes are obtained of a far superior flavour to those hitherto manufactured. The meat and other extracts may be obtained by what is known as the Liebig process, or by any other suitable or well-known method, and in order to exclude the presence of inert substances, composed chiefly of the pulpy parts of vegetables, it is proposed, in the case of carrots, cabbages, and such like vegetables, to remove them from the preparations directly they have parted with their juices.—Patent abandoned.

52 W. WEBSTER, Dundee. *Softening hemp, &c.* Dated January 7, 1869.

This consists of a tube which is placed across the machine above the softening and breaking-up rollers, and supported at each end by brackets attached to the framing of the machine, or in any other convenient manner. A valve box is situated in the centre of the pipe, and fitted with a valve at each end, by means of which communication with each section of the tube is cut off when the machine is not operating. The valves are fitted with long spindles or rods which pass through the tube at each side of the machine, each end of the tube being fitted with a suitable gland and stuffing box. A coiled spiral or other spring is placed in the valve box between the valves, so as to keep them closed on their ends when the machine is not operating; and when the machine is operating, the valves are opened by inclined bars or wedges, which are fitted to the bearing blocks of the softening rollers.—Patent abandoned.

53 J. J. BODNER, Newport. *Iron and steel.* Dated January 7, 1869.

This consists in a process by which one or more balls from puddling furnaces or other furnaces or apparatus, or a whole charge or part of a charge, either formed into balls or in the state of springy iron or steel, before being balled may be shingled, hammered, or compressed into one bloom, or such balls or springy iron or steel together with iron and steel in pieces or bars may be so treated. It is a process altogether different from the so-called "doubling." In doubling, the first ball is tapped or flattened before the second ball is added to it; the first two balls together may then be so treated, or a third ball may be added to them, and so forth. In working this new process, however, the whole weight or quantity of iron or steel, or of both, which is to be formed into a bloom is put into a mould, and is forged or compressed into a bloom. One or more holders or receivers are charged from one or more puddling furnaces or other apparatus, and are couched to the mould, which may be placed under a hammer or press or other compressing apparatus, and their charge or charges may be tipped or put into the mould. Or the mould itself may be conveyed to the furnace or apparatus containing the iron or steel, and be filled there and taken to the hammer or other compressing apparatus, or a stationary or movable compressing apparatus may be used at each furnace. In cases in which it may be desirable to have different qualities of iron or steel or iron and steel in the same bloom, such iron and steel may be charged in pieces or bars at a welding heat, put into its position in the mould, and the balled and springy iron or steel may be added. Pressure may then be applied by one or more hammers or by one or more hydraulic rams, or by a combination of both or in any other convenient way. The mould may be provided with slits or perforations or hollow parts for the escape of the slag. End plates in the shape of gratings or perforated may also be used for the same purpose.—Patent abandoned.

54 H. G. FAIRBURN, Goswell-road. *Compressing coal, &c.* Dated January 7, 1869.

This consists in improvements in that class of machinery for compressing and solidifying coal, clay, and other substances, for which letters patent were granted on December 14, 1865, No. 3242, in which the blocks of fuel are formed by passing them through a tube in portions divided and shaped by pallets or dies; and the present invention consists, first, in improvements in the construction of the cylinder portion of the machinery, the objects being to economize the consumption of steam, and to prevent breakage or injury to the dies or pallets; and, second, in an improved arrangement for introducing the dies or pallets into working position; and, lastly, in an arrangement whereby for pressing coal and other substances that require the pallets to be cool, the said pallets may, after having been in contact with the heated material, be cooled before being re-introduced into the machine; while for pressing peat and other substances that require the pallets to be hot, the said pallets can be introduced into working position in a highly heated state.—Patent completed.

55 C. KENDALL, Mile-end. *Communication in trains and working breaks.* Dated January 7, 1869.

This invention is based on a previous patent, No. 3083, of 1864. The first part consists in employing vertical pumps, combined or separate, to fill the receiver tube with compressed air, and in actuating them by an intermediate wheel. These pumps have one end open, and water is caused to fall on the buckets or pistons to keep them lubricated, a water well formed by a bent pipe being in connection with the air tube. Sometimes a donkey engine is employed to work the pumps. The joints are loop hinged, and have a bolt passed through them to retain them in place; on the train being disconnected, the bolt is withdrawn, and the joints separated. A valve in each part of the joint closes and retains the air in the pipe of each carriage, or the joint end of the pipe is bent, which acts upon a catch lever and separates them. An air cylinder is fitted under the screw shaft of existing breaks, the piston of which when raised is caused to apply the breaks without turning the shaft. A cock having four ways is fitted at each end of the carriage, and a partial movement of a spring lever attached to the plug when a cord is pulled opens a passage leading to a ball connected to the receiver, and an alarm sounded; if the cord should break or be cut, an additional movement of the spring takes place, when the whistle on the engine or other part of the train will sound, and a semaphore or light be exposed to indicate the particular compartment the signal came from. The stem of the whistle is fitted with a valve which closes the passage when the pressure exceeds certain limits. The second part consists in dispensing with one of the pipes, say No. 2 pipe, and retaining No. 1 pipe, which is kept constantly charged; the air keeps a piston to the top of a cylinder in the guard's van, and the piston rod against a bell; on a cock being turned by any cord being pulled, the air escapes, the piston lowers itself, and the bells commence ringing. Sometimes the cylinders are compressible; a spring causes them to collapse, and by being in connection with the whistle handle, moves it and sounds an alarm. Sometimes the apparatus connected with the driver's whistle is made more sensitive than that connected with the guard, so that the driver is acquainted that the pipe is getting empty. Sometimes the pistons may be worked by hand, and when the pipe is fully charged, the piston is weighted to retain the pressure. Sometimes two receivers are employed, one of small dimensions and power for working the signals; the other, of a larger size and power, for working the breaks.—Patent abandoned.

56 J. MANGNALL, Glasgow. *Coffee pots.* Dated January 8, 1869.

A cylindrical vessel is divided into lower and upper compartments by a diaphragm made by preference with its centre depressed, and with an open topped tube projecting up from it. A tube of a little larger size is provided to place over the diaphragm tube, and the upper end of this outer tube is closed, whilst a perforated straining disc is fixed to its lower end. In using the apparatus, a little water is placed in the lower compartment, the outer tube is put in its place, the coffee is put in the upper compartment, and the remainder of the water (boiling or nearly so) is poured also into the upper compartment. The flame of a spirit or other convenient lamp is then applied to the bottom of the lower compartment, and the steam produced rises up the diaphragm pipe, descends by the outer pipe, and rises up through the coffee. When this action is considered complete, the lamp is removed, and a vacuum being formed in the lower compartment, the water in the upper compartment is by the atmospheric pressure made to pass down through the coffee, and by the tubes into the lower compartment, whence it is withdrawn by a stopcock. An air tube with a plug is by preference provided in connection with the lower compartment to facilitate emptying and filling it.—Patent abandoned.

57 W. TATHAM, Rochdale. *Preparing cotton.* Dated January 8, 1869.

The chief improvement consists in a new method of obtaining the accumulation of material necessary to convert the sliver of a breaker carding engine into a web to be fed to a finisher carding engine. The sliver combed from the doffer of the breaker carding engine is passed over one or more rollers, the last of which has a light top roller laid upon it, or it is passed over a creeper to a pair of rollers, which feed it to a propelling beater, which may be formed either in the usual way, with teeth, or bars, or of bristles, or similar materials. This beater works in a space closed above it, has a series of openings or grids underneath, or it may be enclosed there; also in certain cases, except at one part which communicates with a recess expanding from the surface of the beater, at which point it is narrowest, to a pair of cage rollers enclosed at the other end thereof. The beater takes the material from the delivering rollers above described, and throws it into the expanding recess, where it accumulates against the cage rollers. In this condition of accumulation it is very diffuse and puffed up with air. The inventor communicates a slow rotary motion to the cage rollers, which by gathering the puffy mass has the effect of excluding the air, collecting dust and conveying the web continuously to a pair of clearing rollers, which may either pass it direct to the finisher engine or for the purpose of being seen and examined, there may be a space left between the clearing rollers behind the cage rollers and a pair of delivering rollers which feed the finisher engine, the said space being filled with rollers, a creeper, or a polished plate of metal. The apparatus described, will supply from the filmy sliver of a breaker carding engine a suitable continuous web, thick, comparatively uncondensed, and uniform not only longitudinally but across from selvage, as distinguished from webs which are folded or rolled and cut and joined, and have necessary inequalities when fed to the finisher engine.—Patent completed.

58 T. P. LUCAS and G. H. J. HOLT, Kent. *Carte de visite.* Dated January 8, 1869.

The carte de visite portrait or pictures are first inserted in pieces of cardboard, having spaces cut out to receive them. On the top of these cards are fixed loops composed of wire or other material, through which a rod is inserted. The ends of this rod is fixed into two separate triangular pieces of wood, cardboard, or other material, the whole being closed in, so as to form a box with glass inserted in the front and back, through which the pictures are viewed. When exhibiting the pictures, all that is necessary is to open the triangular box and turn the cards over, they revolving on the rod before mentioned.—Patent abandoned.

59 J. DAGLISH, Seaham Harbour. *Lubricating axles* Dated January 8, 1869.

This consists in the application of circular brushes of bristles or equivalent materials to grease the axles of wheels of coal tubs or other waggons whilst moving over the rails. The oil, grease, or other lubricating matter is deposited in a box below the shaft on which the brushes revolve, in such a manner as to allow part of the brushes to be constantly immersed in the lubricating matter. The necessary motion to bring the lubricating matter up to the axles is obtained by having a ring or disc of india-rubber or other suitable material attached to one or two wheels or discs on the circular brush shaft, or on an auxiliary shaft, the ring or disc being of a sufficient diameter to allow it to come in contact with the axle of the tub or waggon, whereby a partial revolution of both discs and brushes is effected. This movement brings the part of the brushes immersed in the lubricating matter up against the bearing of the axles, thereby causing them to be uniformly and regularly lubricated. The india-rubber disc may be attached either to the circular brush shaft or to a second shaft, which gives motion to the brush shaft, by means of spur gear or friction wheels of india-rubber or other material, or by other suitable known means of transmitting motion, so as to cause the brush shaft to revolve at a greater or less rate than the india-rubber disc, according as it may be wanted and in an opposite or in the same direction as required.—Patent completed.

60 R. WIGRAM, Leeds. *Ploughs.* Dated January 8 1869.

This relates to a previous patent, dated July 16, 1867, No. 2088. The invention relates, first, to simplifying the construction of the framing of the plough, whilst still retaining the capability of moving the ploughs towards or away from one another to adjust the width of the furrow. For this purpose, in place of making each plough capable of sliding to and fro upon two bars fixed transversely across the frame, as heretofore, the inventor arranges all the ploughs, so that they may be shifted to and fro on one bar, which passes across the frame at an angle, and be connected to it at different points along its length, so that the ploughs not only come one behind the other, but also can be set nearer to or further from one another by varying the points at which they are connected to the bar. By this means, the plough may be made at much less cost than heretofore.—Patent completed.

61 A. B. BROWN, Cannon-street. *Cranes and pumps.* Dated January 8, 1869.

For raising and conveying weights, the inventor employs a crane, the lifting chain of which is actuated by an hydraulic cylinder and ram, each carrying a pulley or pulleys, around which the chain is passed in such a manner that, when water is admitted to the cylinder and the ram caused to move outwards, the length of the chain extending between the pulleys is increased, and consequently the weight attached to its free end is raised. This construction is well understood; but the invention consists in an improved arrangement for supplying water under pressure to the hydraulic cylinder, so that, if desired, the whole apparatus may be mounted on a carriage as a travelling crane. This arrangement consists of a steam boiler working a small pumping engine, and having in connection with it a cylinder into which the steam or water of the boiler is at all times free to enter. This cylinder contains a ram which the pressure tends constantly to force outwards. The ram carries another smaller ram working in a corresponding cylinder containing water, and the pressure on the larger ram tends to force the smaller into its cylinder. The water is thus contained in this cylinder under a very heavy pressure, and the cylinder serves as a reservoir from which water under pressure is drawn as it is required by suitable valves to work the crane. As the water is allowed to pass out of the supply cylinder, the ram, which is directly exposed to the pressure in the boiler, moves outwards, constantly maintaining the pressure on the water in the supply cylinder, and, in moving outwards, it opens the steam valve, admitting steam to the steam engine, which immediately commences to work, pumping water into the supply cylinder until it is again full, the larger ram being at the same time forced back into its cylinder. When the supply cylinder is full, instruments in connection with the rams close the steam valve, and the engine is stopped. The supply cylinder will then contain a charge of water ready to work the crane at any moment. The pumping engine preferred consists of a steam cylinder with steam and exhaust passages arranged in the usual manner, and ports over which a slide valve works. On the valve rod are two small pistons, one at each end, working in corresponding cylinders; and each of these cylinders has a steam passage connecting its inner end with the main cylinder, and also an opening or escape passage near its other end. The small pistons working in these cylinders have small holes or leaks through them, but, the area of these is much less than that of the escape passages before-mentioned. The steam passages connecting the main cylinder with the smaller cylinders open into the main cylinder at short distances from its ends, so that the piston, when it gets near the end of its stroke in either direction, passes one of these passages, and the steam rushing through it immediately, blows over the valve, the motion of the small piston on which the steam comes being opposed only by the pressure of the atmosphere.—Patent completed.

62 W. T. WAITE, Salisbury-square. *Treating saccharine matters.* Dated January 8, 1869.

This consists in the employment of certain neutral insoluble finely divided substances prepared by precipitation, or in the employment of an intimate admixture of an acid compound and a basic compound in such proportions that, when the mixture is put into water or into a saccharine solution, it will form a neutral insoluble finely-divided precipitate. The neutral insoluble finely-divided precipitates which are employed for the purpose of the invention are hydrate of peroxide of iron, phosphate of lime mixed with carbon, phosphate of iron, phosphate of lime, phosphate of alumina, and carbonate of iron. Of these, the preference is given to hydrate of peroxide of iron and to phosphate of lime mixed with carbon, as it has been found from practice that they give the best results. To manufacture an insoluble precipitate of phosphate of lime mixed with carbon, the process is preferably as follows:—The inventor takes, say, 100 parts by weight of powdered animal charcoal, 50 parts of sulphuric acid, and sufficient water, say 1,500 parts, and mixes them, allows them to stand for a time, and then adds about 26½ parts of lime, stirring the whole well together. The phosphate of lime which was in the charcoal is formed into an insoluble finely-divided precipitate. After it has been washed and allowed to settle, the water poured off this precipitate is ready to be put into the saccharine solution for the purpose hereinbefore stated, or the precipitate may be partially dried, and then added to the saccharine solution. Instead of animal charcoal, any other source of phosphate of lime, such as coprolite, apatite, and guano may be employed, but when any of these last-named substances are used, the product is phosphate of

lime unmixed with carbon. Instead of sulphuric acid, any other acid, such as hydrochloric, which will render the phosphate of lime soluble, may be used, and, instead of lime, any other base or alkali, such as alumina, oxide of iron, or soda, which will make a finely-divided precipitate, may be employed. In preparing any other finely-divided precipitate, a solution of the base or any soluble compound of the base is taken and precipitated by a solution of the acid or any soluble compound of the acid.—Patent completed.

63 T. B. SYDSERFF, Bucklaw, N.B. *Ballot voting.* Dated January 8, 1869.

This consists of a voting ball receiver, of crystal or other transparent substance, placed in front of a screen or partition, behind which the ballot boxes secured by lock and key are placed. The voting ball is deposited in the crystal or other receiver by the polling sheriff or other officer, and is exposed to public view. The said receiver is closed at the bottom by a slide valve retained in position by a spring india-rubber band or its equivalent, the ball when released by the slide valve passing down a sloping tube through a covered funnel into an inclined delivery tube turning on a vertical spindle, the said delivery tube passing through a traversing quadrant or segment of a circle, under which the ballot boxes are placed in close proximity thereto, and in such a position that the delivery tube, actuated by a voting handle attached to the quadrant, will cause the ball when liberated to drop into the desired ballot box. The voting handle is moved by each voter as he passes into the enclosure to a point under the name board of the candidate selected by him, and, when released, is retained by a notch in a disengaging bar behind the voting rail. The voter, now passing out in the opposite direction to that by which he entered, throws open a voting wicket closed by a spring hinge or otherwise, and a cord or wire attached to the heel post of the wicket draws out the slide in the crystal or other receiver, causing the voting ball immediately to descend to the appointed ballot box, and, as the traversing quadrant continually covers all the ballot boxes, no ball can enter either of the said boxes except the one placed in the crystal or other receiver by the sheriff. Having passed through the first or voting wicket, the voter then passes through a second or departure wicket, from which a rod, wire, or cord is attached to the disengaging bar, depressing it, and relieving the voting handle from the notches therein, causing the handle to swing back to its original position by means of a weighted cord passing over a pulley, or otherwise, or the disengaging bar may be depressed by the action of shutting the voting wicket, if desired. The voter having passed out of the enclosure, the sheriff or other officer admits another voter to repeat the same process, but no voter can touch the voting balls nor approach the ballot boxes to interfere therewith.—Patent completed.

64 J. RODGERS, Sheffield. *Furnaces.* Dated January 8' 1869.

The firing hole is of the ordinary construction, and the hot air passes over a bridge into a cavity, and is there met by cold air which is admitted through pipes, and thence passes along the furnace to the chimney at the other end, thereby distributing an equal heat over the whole area of the furnace, and also consuming the smoke.—Patent abandoned.

65 M. WILKIN and J. CLARK, Paddington. *Railway brakes.* Dated January 8, 1869.

This relates to patents granted to John Clark, dated October 20, 1862, and May 13, 1867. In the present invention, a carriage framing has the leverage increased for applying the brake, and, consequently, the strain on the operating line diminished. The wood brake blocks are suspended from pins in the framing. Cross ribs connect the blocks on the same end together, and pulling rods connect the cross ribs with the leverage for applying the brake. The rods on one end are jointed to a racket bar, and those on the other end are jointed to the lever. Parallel guides keep the rods in centre line. At the lower end of the lever is fixed, in slotted eye or taking-up pawl, a chain attached to winding mechanism in the van or on the tender. This chain is carried on sheaves in brackets fixed to the framing. It is passed down under the sheave in the lever, so that, by tightening the chain, the lever is raised and operates the pulling rods attached to it. At the bottom end of the lever is fitted a shoe with ratchet teeth cut upon its lower face to suit the rack bar. The shoe provides a fulcrum for the lever to pull the rods. At the other end of the carriage, when the lever is raised, the take-up pawl is pushed forward in the link eye, so that when the blocks are much worn and the lever rises near the top of its range, the take-up pawl mounts into a fresh tooth of the rack bar, and, when the lever is again lowered, the shoe is pulled over into a fresh tooth also, and thus the wear of the blocks is maintained to keep the short fulcra of the lever in effective position. Sometimes, instead of a flat ratchet bar, a round ratchet wheel is used. To the spindle of the said wheel, chains connecting the rods would be attached, or the spindle could have an ordinary pinion cut upon it working in a rack attached to the rods. In an improved arrangement to pass the operating chain from carriage to carriage without being affected in its length by the shrink of the buffers or the drawbar being pulled out, the chain is led over and under the sheaves, and, because the bottom pair of sheaves at the end of the swing links are kept an uniform distance apart, the chain is not materially affected by the varying length of the train.—Patent completed.

66 J. HENDERSON, Auchencairn. *Iron and steel.* Dated January 8, 1869.

The furnace may be termed a double reverberatory furnace, as the hearths, four in number, are arranged two in a line and placed back to back to receive their heat from one and the same fire chamber. In this chamber the inventor uses waste or small coal as fuel, with a blast of air on each side, which consumes all cinder and enables the heat to be kept up night and day without any stoppage whatever from cleaning or renewing the fire. Any number of hearths thus arranged may be placed side by side; but it is preferred to arrange them in groups of two for the purpose of welding the blooms in the furnace clear of scale, for the production of large masses for armour, slab, girder, or rail direct, and thus save the cost of filing. Each hearth is surrounded with air flues, and air-flues are also formed beneath the hearths, which are all regulated by inside and outside dampers supplying the same from the external air, and allowing them to discharge heated air into the furnace a little above the boshes of the hearths, as required. In the middle wall, dividing the two lines of hearths, the inventor forms flues for discharging in a heated state air admitted to the furnace through openings at the base of a common vertical shaft which serves to carry off the gases of combustion. In the bottom lining of this shaft, just below the metal mantle-plate carrying the top part of the shaft from top of cast iron pillars, air is admitted which circulates along each roof of the fire chamber for discharging in a heated state into the rising gases, and then igniting them over the fire bridge which effects complete combustion and gives off any kind of flame required.—Patent abandoned.

67 W. E. GEDGE, Strand. *Closing boxes.* (A communication). Dated January 9, 1869.

This consists in clasping and setting together the edges of the lid and of the body of the box so that they form, as it were, but one piece, the operation of soldering them together being thus dispensed with. This clasping leaves nothing to desire as regards adhesion and hermetic closing, which are so thoroughly effected that no leakage can occur when the boxes are submitted to the operation of boiling. The whole of the clasping is effected by this machine, which by means of compressing or milling tools, wheels, or rolls set as hereinafter described, so bends and folds together the tin of the lid and of the body of the box so that these become united in an inseparable manner.—Patent completed.

68 R. LEGG, Clerkenwell. *Motive power.* Dated January 9, 1869.

This consists in the utilization of the resistance offered by surface friction, internal projections, bends, or other obstructions to the free passage of steam or fluids through pipes or other passages, and in the application of this resistance as a fulcrum or abutment for the steam, in order to obtain motive power without the use of a piston. This is accomplished by compelling the steam to pass through a considerable length of cranked or tortuous passage in its way from the generator to the atmosphere or condenser, and by forming this passage in coils or folds about an axle which is thus forced to revolve with a power about equal to the amount of free energy lost by the steam in struggling through the passage.—Patent abandoned.

69 F. S. THOMAS, Islington. *Railways.* Dated January 9, 1869.

This principally relates, first, to railway passenger carriages; second, to the carriages of railway locomotives. The invention consists in constructing the carriage portion of the locomotives in such a mechanical form as to make them flexible longitudinally by being jointed transversely between each pair of wheels so as to convey the rigid portion of the steam machinery upon flexible carriages. For this purpose, each compartment of the carriage is provided with an axle which revolves at its centre and is controlled by guide arms and wheels, so that the locomotives are not disposed to run off the rails nor to grind against them at the curves, but to render easy obedience thereto. The invention, third, relates to railway travelling buffers. The inventor constructs buffers of two descriptions. He constructs for each train two travelling preparative buffers which take the form of separate carriages, one of which is placed in the front of every train and one in the rear thereof.—Patent abandoned.

70 M. SAUNDERS, Tipton, and H. FORREST, Oldbury. *Refrigerators.* Dated January 9, 1869.

This consists in providing a coil or series of continuous coils of metal or other suitable double tubing, that is to say, two tubes, one contained within the other, the inner tube being for the purpose of containing the flow of liquor, the outer tube or jacketing surrounding the inner tube and containing the stream of water or cooling medium. The water and the liquor are caused, by preference, to flow in opposite directions, the water tube being connected to a reservoir or main at the one end or junction of the coils, and the inner or liquor tube is connected to the vat or other suitable vessel at the other end, containing the liquid requiring to be cooled. The flow of the water or the liquor may be regulated by means of suitable regulating taps or valves, and it is proposed in some cases to form in the outer tube outlet valves with taps communicating to small cisterns in any part of a building for slop purposes, the supply being obtained when a suitable degree of force is exerted upon the water flowing through the outer tube. By the construction of refrigerators as described a great saving of the cooling medium with more certain results are obtained, the apparatus being also produced at a less cost than those in general use.—Patent completed.

71 E. GRAY, Sheffield. *Plough coulters.* Dated January 9, 1869.

This consists essentially in welding together bars of wrought iron and steel, which welded bars are by rolling or hammering tapered from back to edge and subsequently forged into plough coulters, or they may be rolled or hammered into flat bars and made into coulters. The welding of the iron and steel together is accomplished either by pouring melted steel on one side or end, or on both sides or ends of the wrought-iron bar, or in the middle of or between two iron bars, whilst it or they are in a heated state and contained in a suitable mould, or the iron and steel bars may be welded together by hammering or rolling.—Patent completed.

72 T. MOORE, Southwark. *Rotary engines.* Dated January 9, 1869.

An outer cylinder or bored cylindrical casing is employed with two end covers suitably constructed to receive a shaft or axis through their centres, the passage of the shaft or axis being made watertight. On this shaft or axis is fixed a cylinder, drum, or piston, leaving an annular space between its circumference and that of the outer cylinder or bored cylindrical casing. The periphery of this cylinder, drum, or piston is suitably formed to receive two, three, or more hinged buckets, fans, or flap valves, which hinged buckets, fans, or flap valves are actuated by means of a cam or cams of forms convenient to the purpose. The cam or cams are placed in a recess formed in one of the end covers, and through the intervention of rollers and levers cause the hinged buckets, fans, or flap valves, during part of a revolution of the machine, to obstruct in a watertight manner the annular space left between the outer cylinder or bored cylindrical casing and the cylinder, drum, or piston, and during the other portion of a revolution to lie in recesses formed in the periphery of the cylinder, drum, or piston for this purpose. It is by the action of water properly introduced by an inlet pipe on to these hinged buckets, fans, or flap valves that a rotary motion is imparted to the cylinder, drum, or piston, and motive power obtained, the waste or used water being of course permitted to run away through an exhaust passage or outlet pipe.—Patent abandoned.

73 A. BAUMANN, Strand. *Hydraulic cranes.* Dated January 11, 1869.

For the purpose of supporting the apparatus hereinafter mentioned, a bedplate, carrying a crane jib, is provided, the bedplate being so arranged as to turn round a crane post fixed to a carriage, so as to form a travelling crane. On the bedplate is placed a steam boiler, with one or more steam pumps connected to it, which pumps are so constructed as to throw water as soon as the cock or valve of the water delivery pipe is opened, as is the case with many direct-acting steam pumps now in use. When the delivery cock or valve is open, the steam pumps throw the water, which is drawn from a tank placed on the bedplate into one or more cylinders, provided with pistons or rams working therein, and which are moved by the pressure of the water, and have rods connected directly or by means of pulleys to the chain which passes over the jib, and to which the weight to be lifted is attached. By preference, one or two steam pumps of sufficient dimensions to throw in one stroke the quantity of water necessary for one lift, is or are employed, the same not being worked at a great speed.—Patent abandoned.

74 J. HOLDING, Manchester. *Temples for weaving.* Dated January 11, 1869.

This consists in forming a transverse slot in that portion of the "temple" bracket in contact with the temple bar. This slot terminates in a hole passing through the end of the bracket, the outside surface of which is faced. The bolt retaining the temple upon the bar is formed with an eye, which is received by a transverse slot and through which the bar is inserted, the screw shank projecting from the eye being caused to pass through the bolt hole forming the termination of the transverse slot. Thus the nut, when placed upon the screw shank, can be got at with the greatest ease by the operative for the purpose of adjusting and fixing the temple upon the bar.—Patent abandoned.

75 F. N. GISBORNE and H. ALLMAN, West Strand. *Signals.* Dated January 11, 1869.

The inventors employ a flexible cord, made either of vegetable fibre, such as hemp, or of metallic wires, or wire used singly or in the form of a twisted cord. This cord communicates at one end with a steam whistle or other sound-giving apparatus on the engine, the other end being fixed to a large drum in the guard's van, which keeps the rope tight by the action of a weight. At intervals the cord is supported and kept in place by spring clips fitted with friction rollers. The spring clips the spring frames to rollers, which open on the upper side so as to allow the cord to be pushed in. The invention comprises, first, the peculiar construction of whistle or other sound-giving instrument, which allows an interval of time to elapse after being put in motion before giving any sound. This interval is necessary to prevent signals being given by a momentary slack in the cord. Second, the form of friction roller spring clips as hereinbefore described, which enables the cord to be very quickly strung in gear after the train is made up. Third, a peculiar form of cutting apparatus of the same form and construction as a cutting pliers used in cutting wire, for cutting the cord fixed to each carriage, which cannot be moved or used without destroying an envelope. Fourth, an apparatus fixed to the weight pulley in guard's van for ringing a bell by the fall of a weight on the cord being cut. Fifth, an electric apparatus, used for the similar purpose of making signals, consisting of an apparatus on the engine, being a permanent magnet, and a soft iron electro-magnet, which, by their adhesion together, keep the whistle cock shut. But when a current of electricity is sent from the guard's van, which contains a battery, through the conducting wire, magnetism is induced in the electro-magnet on engine, which, being repelled from the permanent magnet, opens the whistle. Sixth, the employment of wire, cord, and suitable cutting apparatus, as hereinbefore described. Seventh, an india-rubber air ball, which delays the action of the steam whistle.—Patent abandoned.

76 J. KNOWLES, Droylsden. *Weaving terry, &c.* Dated January 11, 1869.

This consists principally in floating the terry or thick threads for forming the loops of the pattern or figure in the following manner:—When making the plain or ground cloth, the terry or thick thread (or threads) is floated three picks on the under side or back part of the cloth, and one over or on the front side of the same, but when required for the figure or pattern it is floated two picks above and two below. This method of weaving makes the plain cloth or ground much smoother than the ordinary method, and causes the figure or pattern to stand out much more prominently, and gives a much superior appearance to the article woven. In carrying out this invention, instead of using the jacquard apparatus as a slackening motion for drawing the yarn (required for the loops) off the creel, the inventor places the jacquard apparatus nearer to the front of the loom and between the healds and the back of the reed, using it only as harness to float the threads required for the pattern, and then causes the beating up of the "slay" in knocking up the weft to the cloth to draw the terry or thick threads from the creel and throw up the loops.—Patent completed.

77 J. JORDAN and J. JORDAN, jun., Liverpool. *Propelling vessels.* Dated January 11, 1869.

The inventors attach by any known means to the sides and bottoms of vessels a parallel, or nearly parallel, casing, extending for a required distance fore and aft, such distance being determined by the nature of the inlet and outlet passages. This casing may be set at any required distance from the sides and bottom of the vessels depending upon the area required for propelling effect. The casings are to be open at the forward and after ends for the entrance and exit of the water used in propelling the vessel. Into this chamber a series of conveniently arranged nozzles, suitable for steam jets, are introduced, when, upon turning on steam generated in any way, currents of water will be drawn in at the fore end of the casing, and driven out at the after end of the casing with any required velocity. The inventors propose to make the casing before mentioned extend from the keel to the light or load-water line, and the series of steam jet nozzles to be placed in sections, so that one or more can be used. For reversing the motion of the vessel, the direction of the current will be reversed by suitable means outside the vessel.—Patent abandoned.

78 T. A. WARRINGTON, Kentish Town. *Clips for window blinds.* Dated January 11, 1869.

The inventor secures the blinds to their rollers by means

of clips made of sheet metal, and peculiarly formed, so as to render them capable of being easily pushed on to or withdrawn from the roller by the use of one hand whilst the blind is held by the other, so that the removal of the roller from its place to take off or put on the blind is not required. The blind is first placed against the roller, and then the improved clips are sprung or pushed on at suitable distances apart, by which means the blind will be held securely in position. Each clip consists of a peculiarly formed spring, constructed somewhat in the form of the lyre of the ancients, or of the letter U, having its upper parts situated nearer to each other at their tops than in the body of the clip, the top edges of such upper parts being curved outwards, and rolled up so as to facilitate the operation of placing the clip in position, while, at the same time, it will remove all such risk of injury to the blind as might otherwise occur from its contact with the sharp edges of the metal.—Patent abandoned.

79 J. B. Palmer, Handsworth. *Firearms.* Dated January 11, 1869.

This consists substantially in the use of an elongated metal cap, having an aperture drilled through the centre of its apex. Around the base of the cap is fitted a movable metal ring, which works between the sight protector hereinafter described and the rim at the extreme base of the cap, and which is for the purpose of securing the cap upon the nose of the barrel when adjusted thereon. The sight protector is a piece of metal projecting from the side of the cap, having an aperture sufficiently large to cover and protect the foresight when adjusted thereon. The aperture through the apex of the cap is closed, either by means of a suitable cover, or, if preferred, a muzzle stopper of an ordinary kind may be inserted inside the elongated cap, but in this case it is preferred that there should be attached to the upper part of the said stopper or screw which goes through the aperture of the apex of the cap, and is secured thereon by a stopper head of any suitable kind.—Patent abandoned.

80 J. Petrie, jun., Rochdale. *Washing wool.* Dated January 11, 1869.

This relates, first, to those machines for washing wool and other fibrous materials in which a swing rake, as it is commonly called, is used, and consists in a method of balancing the said rake. Second, in a method of altering the throw or vibratory movement of swing rakes. Third, to the lifting apparatus, and consists in a method of raising the material from the trough and delivering it on to an endless apron, or into a suitable receptacle.—Patent completed.

81 W. H. Penning, Hertford. *Signalling.* Dated January 11, 1869.

The mechanism consists of a reservoir fitted with valves, in which the compressed air is contained, and of one or more reservoirs, to be used as may be necessary. A communication tube, extending in one or several lengths, which can be attached to or detached from each other at pleasure, is led from the air reservoir to the place or places at which the signals are to be given. A whistle or other alarum at each or either end of the tube of communication has a stopcock for turning off the air at such times as may be necessary. At every place from which signals will be transmitted a lever, handle, knob, or other arrangement, acting on the outlet valve of the air reservoir, is connected therewith, by which the valve can be opened, and all or any portion of the compressed air allowed to escape.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated July 26, 1869.

2270 R. Shaw, Higher Walton, near Preston, Lancashire, and R. Lakin, Manchester. Certain improvements in carding engines.

Dated July 27, 1869.

2271 J. Miller, Victoria Park, Middlesex. Improvements in or in addition to the mariners' compass.

2272 C. Henderson, Gracechurch-street, City. Improvements in girders used in the construction of arches or otherwise combined with iron, timber, stone, or brickwork.

2273 M. J. Frisble, Birmingham. Improvements in carriage axles.

2274 J. Winship, York. Improvements in the preparation and application of medicaments for internal and external use.

2275 I. Barker, Stourbridge, Worcestershire. Improvements in the manufacture of coffered spades and shovels.

2276 T. Parsons, Massachusetts, U.S.A. A new and useful mechanism, apparatus, or engine, to be used either in measuring water discharged from a conduit or for various other useful purposes.

2277 D. T. Bostel, Ship-street, Brighton, Sussex. Improvements in what are known as dry earth closets.

2278 J. Windle, Sheffield. Improvements in rolling hoops or tyres of iron or steel.

2279 W. R. Lake, Southampton-buildings, Chancery-lane. An improved apparatus for shearing or clipping animals and skins.

2280 A. M. Clark, Chancery-lane. Improvements in the manufacture and refining of sugar.

Dated July 28, 1869.

2281 W. A. Lyttle, The Grove, Hammersmith, Middlesex. Improvements in electro-telegraphic apparatus.

2282 D. A. Fyfe, Bolton, Lancashire. Improvements in the manufacture of paper, and in the machinery or apparatus connected therewith.

2283 H. Gillan and G. Crawford, Glasgow. Improvements in apparatus for spinning or twisting and rolling tobacco.

2284 F. Crossley, Princes'-terrace, Bonner-road, Victoria Park. An improved method or means of preventing metals from rusting or corroding.

2285 A. V. Newton, Chancery-lane. Improved apparatus for facilitating the grinding of the knives of harvesting machines.

2286 A. Burdess, Coventry, Warwickshire. An improved method of winding up watches and other timepieces, and of moving the hands thereof.

Dated July 29, 1869.

2287 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in weaving looms.

2288 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in weaving looms and in their shuttle boxes.

2289 H. S. Heyman, Manchester. A process by which the waste of flax and hemp is converted into substitutes for cotton, wool, and flax.

2290 A. Smith and D. Cunningham, Stonehouse, Lanarkshire. Improvements in treating and refining crude mineral, petroleum, and other hydrocarbon oils, and in the means or apparatus employed therefor.

2291 J. Tate, Portadown, Armagh. Improvements in machinery for scutching, breaking, and preparing flax, hemp, jute, and other fibrous substances, and for thrashing corn or grain.

2292 D. R. Kilpatrick, Glasgow. Improvements in the application of springs to chairs, couches, or other seats and beds.

2293 W. E. Gedge, Wellington-street, Strand. An improved apparatus for lubricating parts of locomotive and other engines.

2294 T. F. Taylor, Southampton-buildings, Chancery-lane. Improvements in machinery for manufacturing metal tubes.

Dated July 30, 1869.

2295 J. S. Kipping, Manchester. An improved method of fixing colours on textile fabrics.

2296 T. W. Lockyer, Monkwell-street, City. Improvements in ladies' parmiers or bustles.

2297 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in block calendars and other similar articles.

Dated July 31, 1869.

2298 G. Allibon, Rosherville Iron Works, Northfleet, Kent. Improvements in steam engines.

2299 A. Patene, F. Bardoux, and G. Jurie, Rue du Filles du Calvaire, Paris. Improvements in the process of reproducing on wood all engravings through aqua fortis.

2300 J. B. B. Pinchon, Amiens, Department of the Somme, France. An improved apparatus for condensing steam.

2301 C. and T. Watts, St. Mary's-terrace, Paddington-green, Middlesex. Improved means or apparatus for indicating stations to passengers by rail or tramways.

2302 D. Stewart, Glasgow. Improvements in apparatus for concreting sugar-cane juice.

2303 F. Jackson, Wigan, Lancashire. Improvements in lubricators for steam engines.

2304 J. M. Clements, Birmingham. Improvements in sewing machines and their appliances.

2305 C. N. Eyland, Walsall, Staffordshire. Improvements in buckles for articles of dress.

2306 B. Goddard and W. Finley, Stockport, Cheshire. Improvements in machinery or apparatus for mixing substances for pills, ointment, and other purposes, and for making pills and globular articles of plastic substances.

2307 J. O. Milnes and J. Sandiford, Stand-lane, near Radcliffe, Lancashire. Improvements in pins, pirns, or bobbins for shuttles, and in shuttles for pins, pirns, or bobbins used in looms for weaving.

2308 H. S. Edward, South Shields, Durham. Improvements in gearing for auxiliary screw engines.

2309 T. Ramsay, Sherburn Tower, Gateshead, Durham. Improvements in apparatus for the manufacture of gas.

2310 J. Beckett, Llandudno, Carnarvonshire. Improvements in self-acting brakes for railway carriages.

2311 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in direct-acting steam engines.

Dated August 2, 1869.

2312 S. M. Smith, Horton Dye Works, Bradford, Yorkshire. Improvements in dyeing certain textile fabrics.

2313 P. R. Hodge, Adam-street, Adelphi, Strand. Certain improvements in the manufacture of luminous and heating gas from hydrocarbonaceous fluids, and in the methods of using and applying such gas for illuminating and heating purposes.

2314 J. Sharrocks, Red Brook Mill, Bury-road, Rochdale. Improvements applicable to locomotive engines for the purpose of removing obstructions on railways.

2315 L. W. Wright, Brooklyn, New York, U.S.A. Improvements in paddle-wheels.

2316 W. Hosack, Buchanan-street, Glasgow. Improvements in mills for extracting saccharine juice from sugar cane.

2317 F. A. Yeo and H. Hanna, Swansea, Glamorganshire. Improved machinery for the manufacture of artificial fuel.

2318 M. Henry, Fleet-street, City. Improvements in apparatus for ventilating mines, drains, and other places, and extracting noxious gases, smoke, and vapours therefrom, such apparatus being also applicable for communicating sound.

998 H. A. Fletcher	
1001 J. Cruttenden and T. Wells	

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed July 30, 1869.

324 V. Baker	1007 R. Allan
325 J. Slater	1014 G. F. Griffin
331 F. Vanderaey	1077 W. A. Hunter
334 W. Maddick	1097 W. Ashton and J. H. Storey
335 R. B. Frohock	1572 W. H. Dupre
352 H. Jones	1575 C. W. Siemens
354 J. Jobson	1642 J. Bronner and H. Gutzkow
360 J. Taylor	1660 J. Sturgeon
368 H. A. Dufrene	1686 T. R. Clarke, W. Bywater, T. Lawson, and C. L. Lister
425 W. R. Lake	1711 C. Ostlund
458 W. R. Lake	1715 J. Lloyd
468 W. Smartt	1721 J. H. Johnson
483 J. Atkins	1797 W. R. Lake
561 R. W. Farey	
575 R. Morton	
634 J. Farrington	
849 J. D. Morrison	

Sealed August 3, 1869.

356 W. Blundell	573 B. Hunt
357 J. Page	730 W. R. Lake
367 C. S. Dawson	779 J. Thomas
369 J. S. Offord	843 A. V. Newton
378 B. Walker and W. Tilson	858 W. H. Phillips
388 B. Hunt	1015 D. J. Hoare
423 J. Carter	1021 W. Johnson
445 W. Summers	1057 W. H. Douglas
469 L. N. Legras	1158 J. G. Jennings
500 T. H. Martin	1345 E. and T. Waltham
514 S. Myers	1468 T. G. F. Dolby
530 H. W. Whitehead	1563 R. Orley
697 J. A. Jaques, J. T. Oakley, and J. A. Fanshawe	1589 S. Thomas
	1811 G. W. Howe
	1847 B. Wartski
	1864 A. Destouy

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

1959 J. Adams	1986 S. Chatwood and J. and T. Sturgeon
1960 W. Richards	1992 W. Furness and W. Bray
1963 J. M'Kenzie, T. Clunes, and W. Holland	1994 J. T. H. Richardson
1964 T. Greenwood and W. Keats	2001 S. T. Armstrong
1970 J. J. Bodmer	2010 P. Murray
1984 J. Parry and R. Morris	2029 W. Smith
	2039 H. Holland
	2312 C. E. Brooman

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2169 J. W. Woodford	2193 G. Coles, J. A. Jaques, and J. A. Fanshawe
2175 A. V. Newton	
2181 G. A. Biddell	

PROVISIONAL PROTECTION FOR SIX MONTHS

Has been granted upon Specifications bearing the following numbers:—

Notice.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to Robertson, Brooman, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

(Half-size drawing of Chesterman's Patent Steel Measuring Tape, 66 feet.)

JAMES CHESTERMAN & CO.
SOLE MANUFACTURERS OF CHESTERMAN'S PATENT
SPRING, METALLIC, STEEL,
AND OTHER
MEASURING TAPES;
IRON AND STEEL LAND CHAINS;
SINGLE & DOUBLE-ACTING DOOR SPRINGS
ENGINEERS' TOOLS, &c., &c.

BOW WORKS, ECCLESALL ROAD,
SHEFFIELD.

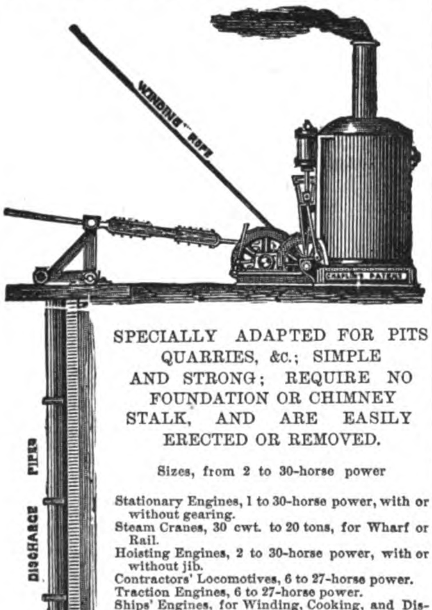
TRADE J C MARK.

A 27

Prize Medal, International Exhibition, 1862.

CHAPLIN'S
PATENT PORTABLE
STEAM ENGINES,
FOR PUMPING AND WINDING.



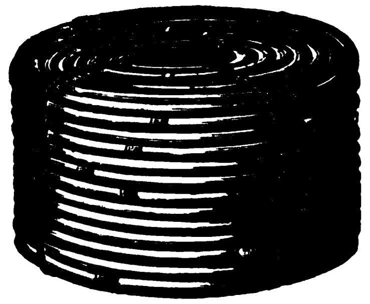
SPECIALLY ADAPTED FOR PITS QUARRIES, &c.; SIMPLE AND STRONG; REQUIRE NO FOUNDATION OR CHIMNEY STALK, AND ARE EASILY ERECTED OR REMOVED.

Sizes, from 2 to 30-horse power

Stationary Engines, 1 to 30-horse power, with or without gearing.
Steam Cranes, 30 cwt. to 20 tons, for Wharf or Rail.
Hoisting Engines, 2 to 30-horse power, with or without jib.
Contractors' Locomotives, 6 to 27-horse power.
Traction Engines, 6 to 27-horse power.
Ships' Engines, for Winding, Cooking, and Distilling, passed by H.M. Government for half-water.
Steam Winches. Engines and Boilers for Light Screw and Paddle Steamers.

ALEXANDER CHAPLIN & CO.,
CRANSTON HILL ENGINE WORKS,
GLASGOW. A 51

PATENT SELF-LUBRICATIVE STEAM AND HYDRAULIC ENGINE PACKING.



This Packing is invaluable to all users of steam power, it supersedes anything of the kind ever invented, it is now in use in the Chief Railways and First Firms in this Country and Abroad, and is

THE ONLY PACKING THAT WORKS WITHOUT OIL OR GREASE,
does not char, is pliable, keeps the rods
COOL, BRIGHT, AND CLEAN,
and lasts longer than any other, thereby
SAVING FULLY 200 PER CENT.
to the user, in oil, labour, and material. Can be had only from the Agents throughout the Country. Appointed by

THE SOLE LICENCEES,
HOUSE AND GARDNER,
1 AND 2, GREAT WINCHESTER STREET BUILDINGS, LONDON, E.C. B 133

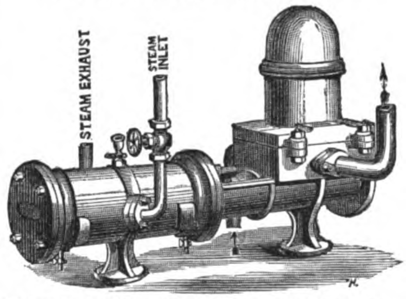
GAMBLE'S PATENT
STEAM LUBRICATOR.
For Stationary, Locomotive, & Marine Engines.

SELF-ACTING.

Lubricates all the valves and internal parts of the cylinder continuously. Effects a most important saving in the oil or tallow. Increases the regularity of working. Prevents frequent repairs.

SOLE MAKERS—
HAYWARD TYLER & CO.,
84 & 85, UPPER WHITECROSS ST., LONDON, E.C.

PATENT
UNIVERSAL STEAM PUMPS,
VERTICAL AND HORIZONTAL.



POWERFUL—SIMPLE—DURABLE—RELIABLE—CHEAP.
Superior to all other Inventions.
SOLE MAKERS—
HAYWARD TYLER & Co.,
84 & 85, UPPER WHITECROSS STREET, LONDON, E.C.
*** Where it can be seen at work.

THE HOUSEHOLDER'S TOOL BOX
Contains every Tool necessary to keep the house and furniture in repair, with full instructions upon the use of each tool.
SOLE MAKERS,
JOHN MOSELEY & SON,
PLANE & TOOL MANUFACTURERS,
54 & 55, BROAD ST., BLOOMSBURY, W.C.
B 234

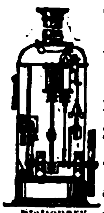
H. MULLINER, COACHBUILDER,
LEAMINGTON SPA,
AND 24, BAKER-STREET, LONDON.
Carriages of every description on View, especially the
PARIS PRIZE MEDAL HICKORY PHAETONS
and other Carriages now so much in use. B 112

BOILER INCRUSTATION. — Hewitt's Patent BLOCK PREVENTIVE COMPOSITION is the simplest and safest in application; warranted harmless in its action on the cocks, &c.; effects a saving of 33 per cent. in fuel. Many improvements have been made in the manufacture during the last four years, and the composition enjoys the highest reputation in the Royal Arsenal, H.M.'s Dockyards, and other Government and many large private establishments in the country. Price 42s. per cwt.—Address to (the principal agent) Mr. HARRIS, 25, Denbigh-place, London, S.W.
N.B.—Engineers are respectfully invited to give the compo a trial.
B 100

MOULTON'S PATENT EMBEDDED STEEL AND INDIA-RUBBER SPRINGS for Railway Carriages, Locomotive Engines, Buffers, &c., possess greatly-increased power, as compared with the ordinary India-rubber Springs; are more uniform in their action, counteract the compressibility of India-rubber alone, and are not liable to break from sudden concussion, or the inequalities of the permanent way.
Prices and further particulars may be had on application to the Patentees, S. MOULTON & CO., Manufacturers of India-rubber Springs, Steam Packing, Washers, Hose, Tubing, Machine Belting, Garments Blankets, Sheeting, Elastic Hot Water Beds, Cushions, &c., &c.
Kingston India-rubber Mills, Bradford, Wilts. A 3

NEW PATENT PORTABLE STEAM ENGINES AND BOILERS.

STATIONARY ENGINES.



Stationary Engine.

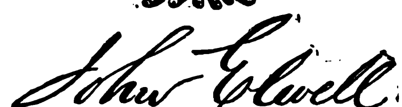
ORDERS FROM STOCK EXECUTED ON RECEIPT.



IRON AND METAL MERCHANT
SNOW HILL AND LIONEL STREET,
BIRMINGHAM.

Rolls turned for any shaped Iron on the shortest notice, free of charge. Books of Sections supplied on Application.

LUXURIANT WHISKERS, MOUSTACHES, EYEBROWS, and a FINE HEAD of HAIR.—A retired apothecary, from Wales, will send his noted FORMULA for 13 stamps and stamp-directed envelope, to produce Hair on the Head, Whiskers and Moustaches on the Face in three weeks.—MR. EVAN EVANS, M.D., C.M., Dorking. Surrey.

LADIES and GENTLEMEN, having a connection, may hear of an AGENCY that will add to their income from £3 to £5 per month. Address (enclosing stamped envelope), JAMES JEFFERSON, Esq., Forest Hill, London, S.E.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, AUGUST 13, 1869.

BARKING AND THE LONDON SEWAGE.

FROM London to Barking, from Barking to Gravesend, and from Gravesend to some more remote locality—some "ultima Thule"—appears to be the past, present, and future destination of the metropolitan sewage. After undergoing a severe scourging from the neglect of obvious sanitary regulations, and losing year after year a good percentage of its overcrowded population, London transferred the contaminating cause of its endemic sufferings to Barking and Crossness. In the opinion of many, this was regarded as a master stroke, a *tour de force*, deserving all praise, and a complete solution of the difficulty. Furthermore, by prohibiting the influx of sewage matter into the Thames above the metropolis, and by the construction of the noble granite walls adorning its banks, it was expected that the term, "pleasant waters," might once more be applied to the river. Probably, but for the incessant disturbing action of the paddle-wheels of the steamers that ply upon its surface, the term might be appropriately used. So far, however, as the discharge of sewage is concerned, the Thames, in the immediate vicinity of London, is free from all such noxious infusions. But it is only thus locally purified, at the cost of what is stated to be a more serious and more extended pollution in another part of its course. It is true that the source of disease may have left the metropolis, but it cannot be said to be conquered; it cannot be considered to be effectually removed, so long as it carries the fever and the pestilence to other towns and localities. If the reduction of the death rate in one town is to be accompanied by a rise in that of another, there will be no diminution in the average return of national mortality. A partial remedy is frequently but an aggravation of the evil. The question at present to be decided is, whether London is to be purified at the cost of the infection of other towns. There is a legal maxim which expressly forbids one man to benefit himself by injuring another, and it remains to be proved whether it may not bear a more extended application. It is written "There is a tide in the affairs of men, which, taken at the flood, leads on to fortune." We are not in possession of sufficient evidence to determine whether the members of the Board of Works regarded this as applicable to sewage and the flood tide of the Thames, but, if so, they appear to have made a most unfortunate mistake. The idea entertained—that the transporting action of the tide would carry the sewage "out to sea," where it would be absorbed and lost in extreme dilution—has eventuated an utter delusion. A large portion of the sewage floats in a vacillating irresolute manner up and down the stream, in the neighbourhood of the outfall, gradually sinking down to the sides and bottom of the river, in a state of almost impalpable subdivision, where it remains in the form of fine black redolent mud. The shores of the river in the neighbourhood of Erith and Greenhithe are evidence of this fact.

At the time that this first transference of London sewage was contemplated, thus distinguishing it from the second transference, which it is now proposed to effect lower down the river, there were some warning voices raised against the scheme—there were some protestations offered against its adoption. In spite of these, the project was carried out, and the results are now apparent in the inquiry which has just been terminated. Although a small place, in comparison with London—a very small place, indeed—yet the inhabitants have at last been roused to action, and may be said to have taken "up arms against a *river* of troubles." There are two points in which the subject has to be considered at Barking. One is the actual sanitary effect produced upon the inhabitants of the town by the discharge of the sewage; and the other, the effect it is producing upon the bed of the river, and the serious consequences that may result to our inland navigation. Were it not for the latter evil and the powerful support that the inhabitants receive from the Thames Conservancy Board, it is somewhat problematical whether the investigation would have taken place. It is probable that the portion of the question relating to the health of the town and its inhabitants will be taken into consideration on some future occasion, as the present inquiry has been confined to the reception of evidence respecting the actual state of the river and the creeks leading into it. On this point, there has been an abundance of scientific evidence taken on both sides. A number of residents in the locality have been examined, and testified to the fact that since the establishment of the outfall works, large banks and accumulations of sewage had been gradually but incessantly forming at the mouth of their creek. Moreover, the depth of water had become so seriously decreased that vessels which formerly found no difficulty in getting in and out of the creek were no longer able to do so, and, what was more to the point, insurance offices would not insure them. It was also stated that sewage matter was found floating on the surface of the water up the creek. In order further to establish the fact that the discharge of the sewage at the outfall had occasioned deposits of mud in the river, the evidence of Mr. Leach, the engineer to the Thames Conservancy Board, was taken at the inquiry. He stated that a gunpowder hulk, which had 13ft. of water under her in 1863, was compelled to be removed about eighteen months ago, as the river had silted up to so great an extent that the barges could not come alongside of her. The fact was also deposed to that before the establishment of the sewage works, the Conservancy dredges met with nothing but clean gravel in their operations, whereas now they found considerable deposits of mud.

Against all this we have the statement of many eminent engineers, including Messrs. Hawksley, Gregory, Bidder, and others, that the whole evil, from first to last, is imaginary, and that the discharge of the sewage into the Thames has had rather a beneficial effect than otherwise upon the bed of the stream. Whether such is the case or not, ought not to be very difficult to prove. It must be borne in mind that it is not a question of opinion, or a matter of guesswork. The condition of the Thames with respect to the quantity, position, and quality of its different deposits and accumulations can be ascertained with minute accuracy from time to time, and the agent at work in producing them indicated with perfect certainty. The chemical evidence demonstrated most conclusively that the banks and foreshores of the Thames are all contaminated with sewage. As the report is no yet made, we shall not anticipate the result, but, in our opinion, not a single drop of the London sewage ought to be allowed to run into the river, and the Metropolitan Board of Works ought to look out for another outlet for it. The idea of effecting a further transference of it to Gravesend or any other locality, with the intention of discharging it into the same channel, is merely a repetition of the existing plan, and one which we trust we shall never witness the adoption of. The present offers an admirable opportunity of giving the only true principle of the utilization of sewage a fair trial, and developing the application of it to land, on a scale commensurate with the importance of the interests at issue. The beneficial results, in an agricultural point of view, accruing from the irrigation of land by sewage are now too patent to need either eulogy or comment. It cannot be forgotten, at the same time, that injunctions are at present hanging over parties for polluting rivers and watercourses by precisely the same course of action that is adopted with impunity by the Metropolitan Board of Works. Why should they be exempt and all other local boards unexempt?

THE CHANNEL PASSAGE.

A REPORT recently made by Captain Tyler to the Board of Trade forms an important step in the progress of this question, and presents, for the information of the public, a most valuable official statement of the present position of the matter. Nothing can be stronger than the opinion Captain Tyler offers of the necessity for improvement in the means by which communication is effected between this country and the Continent. This necessity has frequently been pointed out in this journal, and various plans for meeting it have been described. The testimony of all who have had occasion to experience the existing inconveniences unites in supporting the conclusions of Captain Tyler on this part of the subject. There is no doubt the importance of this communication cannot be over-estimated. In former times, when Europe was regarded mainly as a theatre of war, it was, perhaps, no disadvantage for this country to be separated from it; but since the introduction of steam has so completely changed the character of marine locomotion, any advantage formerly arising in this respect from our insular position has been materially diminished, and, in the present day, it is continental commerce from which we are separated, and not continental wars.

Captain Tyler states in his report that there are on an average only 90 days of calm weather in the year—that is, one out of every four days only. But notwithstanding it is the most important communication in the world, Captain Tyler states that "there is nowhere any sea service of equal importance which is so much in need of improvement." This does not arise from any fault in the vessels by which the service is effected, for he says that it is impossible, for want of sufficient harbour accommodation, to employ better vessels, and that even these cannot at times enter the French harbours or land their passengers on the French coast. Various projects have been designed by means of bridges, tunnels, tubes, and viaducts for avoiding the use of steam vessels altogether, and Captain Tyler states that "those which have of late made the most progress are the bridge scheme of M. Boutet and the tunnel scheme presented under the chairmanship of Lord R. Grosvenor," and he describes the history and present position of both of these. As to the first, he refers to experiments making by an association formed for that purpose, and states "that two small bridges have been built in France, and arrangements are made near St. Malo for a third, a mile in length, in two spans of half a mile each; that the Emperor visited the works on a site which has been granted by the French Government on the 8th June last, and is stated to have expressed himself favourably with regard to the project." The bridge is estimated to cost £8,000,000, and it will take three years to complete, and it is said that the experiments in progress give reason to expect that this estimate will not be exceeded.

Of the tunnel scheme, Captain Tyler says that it has been before two French Commissions appointed by the Emperor to inquire into the scheme, and the Councils General of Ponts and Chaussées, and of Mines, and that the latter, to whom it was last referred, "would not form any estimate either of the probable duration of the works or their cost"

until preliminary driftways "establish the possibility of the undertaking and the nature of the difficulties which may present themselves." It appears that the expense of this preliminary experiment is estimated at £2,000,000, and Captain Tyler's report shows that its success would depend upon whether or not fissures in the chalk are encountered, to avoid which Mr. Remington proposes to tunnel from Dungeness, in order to work in the Wealden formation.

It would be premature to discuss the scientific details of M. Boutet's project, which are not yet published, and, indeed, cannot be determined upon until the result of the pending experiments in Paris is known. We shall look with great interest for these details, as it is evident that a design, which is thought worthy of adoption for spans of half a mile at St. Malo, and the works for experimenting on which the Emperor has thought it worth his while unexpectedly to visit, must possess great merit, whatever span the result of these experiments may show it to be capable of. Captain Tyler, accordingly, necessarily avoids giving any opinion of the feasibility of the project for the Channel bridge, and recommends the English Government to refer the whole matter to the consideration of the French Government, with a view to the appointment of an international commission. We think few will be found to question that a bridge, if practicable, would be preferable to a tunnel. Captain Tyler mentions the following reasons on which it is advocated, and "as being, first, less costly than a tunnel; second, occupying less time in construction; third, giving no trouble in ventilation; and, fourth, avoiding the danger of sudden inundations." We may add, that when completed it would be perfectly reliable as long as it bore its own weight and stood; that it would not be likely to fall without ample premonitory symptoms, which would guard against its use in danger, and be open to the light of day; and during its construction its practicability would be tested as it progressed, whilst the water might break into a tunnel during the excavation of the last yard, or, when completed, during the last mile of the journey, and utterly destroy a train without warning and without hope of escape.

We observe that Captain Tyler considers the necessity of improvement of the Channel passage so urgent that he recommends an immediate expenditure of £500,000 on the extension of the west pier at Boulogne, or £200,000 on a new harbour near Boulogne, for the temporary relief of the traffic pending the consideration of the more important improvement which the bridge or tunnel, if practicable, would afford. We should doubt whether the French Government, which has devoted so much attention to the bridge and tunnel projects, would be likely to entertain the idea of falling back on the improvement of their harbours, on which they have already spent such vast sums in attempting, with such slight results, especially when the expenditure which they are invited to make is five times that proposed for our harbour of Dover, and involves the substitution for the ancient port of Calais the modern harbour of Boulogne, which Captain Tyler admits is considerably out of the route for continental travellers not bound for Paris and places beyond it. They would probably prefer to join in the more complete remedy which a continuous railway would afford, either by tunnel or bridge, more especially as the latter is estimated to cost only £8,000,000, and to require only three years in construction, and it would save the necessity for the double transhipment of goods, which is so fertile a source of damage, expense, and delay.

It is satisfactory to find that the question is at last receiving attention in this country, and that steps have been taken by the influential noblemen and gentlemen who formed the recent deputation to Mr. Bright to make known to him the interest which the Emperor of the French is known to take in the matter, and it is to be hoped that Captain Tyler's recommendation to the English Government to co-operate with him will not be lost sight of.

THE GOLD COINAGE OF ENGLAND.

On Friday last, Mr. J. B. Smith attracted the attention of the House of Commons to a recently published report of the Master of the Mint on our gold coinage, and drew from the Chancellor of the Exchequer some important statements in reference to it. Neither of the authorities in question appear to have a very definite idea of the actual number of gold coins in circulation throughout the United Kingdom, but it is probable that Mr. Smith's estimate of thirty-one millions is not far from the truth. Of this number, the same gentleman assumes that about five millions, or 16¼ per cent., have been so reduced by abrasion as to be below the legal minimum weight.* At the first blush, this appears to be a very serious, if not an alarming, conclusion, for it in reality affirms that of every six sovereigns in circulation one is, according to law, not fit for duty. There are, however, many points to be considered before joining with Mr. Lowe and his co-alarmists in reference to the magnitude and consequences of the evil—supposing it really to exist. If the public had as little protection against the presumed disadvantages of a deteriorated currency as the Chancellor of the Exchequer seems to imagine they have, there would be no ground for dissatisfaction. The process of deterioration or reduction of weight commences with all coins from the moment they pass into circulation, and the first year of their existence is always the most destructive. Then it is that the fine sharp lines of the engraved surfaces and the square edges of the milling are smoothed away and rounded off by attrition. This fact is well known to those practically acquainted with coining operations, and will be readily understood by those who are not. It is impossible to evade this evil so long as coins are decorated by artistic engravings, or protected from clipping by having serrated circumferences, or pass from hand to hand in the daily routine of commercial life. Mr. Lowe asserts that "we issue coins of correct weight to the public, but take no care to keep up the integrity and standard of our money." For this sweeping assertion it is difficult to find a truthful basis. We had always believed that the "integrity" of a coin included both its standard of weight and of fineness, and these, so far as emanations from the British Mint are concerned, have never been disputed since the days of King Henry VIII., who tampered seriously with the coinage, in addition to practising some other vices. Whether the expression of the Minister was intended to incite a desire for, and thus to pave the way to, a re-coinage of gold, or to assist in promoting an international coinage, we know not; but one thing is certain, and it is, that his insinuation as to the non-integrity of the English sovereign was undeserved. As to our "taking no care to keep up the integrity and standard of our money," it must be stated in contradiction that after the calling in of "light gold" some 25 years since, a precautionary measure was taken to ensure the future "integrity," as regards weight at least, of the gold currency. It was simply the only practical mode of accomplishing the object, either then or now available, namely, that of checking by weighment each sovereign or half-sovereign by whomsoever received. This rule is still in existence, but many of the private banks waive its application in favour of their customers, and generally it has fallen into disuse.

At the Bank of England, all the gold coined at the Royal Mint is received in its integrity of weight and of fineness, although the accounts between the two establishments is one of weight only. What is called a standard coinage, so far as the Bank is concerned, consists in a right number of pieces being received from the Mint in return for a certain quantity of gold ingots sent to the latter place. We have reason to know that, in a coinage of seven millions of sovereigns and half-sovereigns just completed at Tower Hill and delivered to the Bank, the "integrity" of the individual coins was so scrupulously maintained, as that tale and weight on the whole quantity positively agreed. Mathematically speaking, therefore, the Mint produced seven millions of coins all of equal intrinsic value. Practically, the variations on either side of the true standard (123·274 grains) were equal and thus balanced each other. The legal limit of such variations, it may be stated, is a quarter of a grain (one halfpenny in value) above or below the theoretical standard just indicated. The automatic balances in use at the Mint are next to being infallible in their action, and it is positive that no gold coin can, by any possibility, reach the Bank which is "out of remedy," either on the heavy or light side of the standard. A knowledge of this fact will enable our readers to estimate at its proper value a statement authoritatively made on Friday, viz., that "there is reason to believe that large masses of new British sovereigns are occasionally treated so as to separate out the heavy pieces, and these are disposed of as bullion; while the lighter pieces, which may all be of legal weight, are preserved and put into circulation." With all deference to the source whence this statement came, we take leave to doubt it entirely. The operation would not pay for itself, even if practised on an extensive scale and with the aid of appliances as delicate as those employed at the Mint. It would be cheaper to "sweat" the newly-minted coins, and thus deprive them of their surplus weight, and those who wished to be dishonest in the matter would be apt to find the simplest means of effecting their object. The fact is, moreover, that although the Mint cannot produce all coins of the true standard weight—owing mainly to the varying density of the metal used—yet very few are issued which reach the extreme legal maximum or minimum allowance of variation. At least eighty per cent. of the gold coins issued from the Mint come within those limits, and, though not exactly standard, they cluster closely to it, and do not differ more than one farthing's value from each other. When guineas were coined by rude mechanical means, many years since, and imperfectly sized, it might have paid to select heavy pieces and sell them as bullion; but with sovereigns and half-sovereigns, as produced at the present time, the idea of doing so is simply—it must be said—absurd. It is unfortunate that those who presume to speak of such matters—and with authority, too—are not practical, or do not enlist the assistance of those who are. As to the "manufactories" for manipulating in a nefarious manner the heavy gold coins of the country, and said to exist in Paris or Brussels, they are myths, and Mr. Aytoun did well in asking for proofs of their existence.

The Bank has its automatic weighing machines, and these are a constant check upon the productions of its sister establishment. There is reason to suppose that nearly a quarter of a million of sovereigns, drawn from the channels of circulation, are passed through the Bank balances every week, and from these the "too light" pieces are eliminated and relegated to the furnace. Is not this having "a care" for the integrity of the gold coinage? That any better plan for protecting the public interests than that of testing

* 122·50 grains.

each coin for weight can be devised, we doubt. From the Bank of England the golden streams flow as from a fountain, and they return, by the effects of the law of supply and demand, to the same place where their "integrity" is always being examined into and reported upon. There really appears to us to be no necessity for a re-coinage of gold, nor, therefore, the expenditure of £400,000 in accomplishing it. New coin is being continually supplied to replace the old and worn money, and it is only essential to coin sufficient year by year to keep pace with the deterioration going on under a natural law. As to the reduction in the standard weight of the sovereign, proposed by Mr. Lowe, and the consequent assimilation of its value to the 25-franc piece of France, we shall say more next week.

In conclusion, it may be remarked that the Chancellor of the Exchequer, in speaking of the annual expenditure of the Mint, omitted to state that the profit accruing to that establishment upon the conversion of the old copper into new bronze coin amounted to £400,000—just the sum named for the production of a new gold currency.

ON THE SURFACE TEMPERATURE OF THE SOUTH ATLANTIC OCEAN.

THERE has just been issued from Her Majesty's Stationary Office, by the authority of the Committee of the Meteorological Office, an atlas of charts showing the surface temperature of the South Atlantic Ocean in each month of the year. We avail ourselves of the introduction to place before our readers an account of this valuable addition to physical science. The region included in these charts extends in latitude from the equator to 60deg. S., and in longitude from 70deg. W. to 40deg. E., passing accordingly beyond the limits of the Atlantic Ocean for a considerable distance around the south point of Africa. The original materials out of which the charts are constructed were collected and discussed at the Meteorological Office before it was placed under the management of the Committee of the Royal Society. It will be seen that these materials consist of monthly mean temperatures for spaces of five degrees of latitude and longitude (five-degree squares). In the extraction of the observations from the registers kept on board ship no notice had been taken of the exact positions of the respective ships, beyond the fact of their being within the area of a certain five-degree square. Accordingly, it would have been impossible to have determined the precise part of the square in which any particular observation was made, without referring back again to the original registers,—a work of enormous labour. The Committee have therefore deemed it advisable to allow the data to appear in their present condition, rather than to delay their publication altogether until a more complete investigation of the subject had been effected.

In order, however, to place before the English public a large amount of additional information which was in a far more detailed condition than their own, they have decided on republishing the data as to the area under discussion, which are contained in the work entitled "Ondersoekingen met de Zee-thermometer," published at Utrecht in 1861 by the Royal Meteorological Institute of the Netherlands. The Dutch discussions have been effected with reference to bands of 5deg. of longitude, but for single degrees of latitude, so that five distinct means are given for the space which is only represented by a single mean in our own results. This is, of course, a very great improvement; but even this subdivision is far from being minute enough to enable us to trace satisfactorily the direction of ocean currents. It is evident that in order to investigate currents running in a meridional direction, each observation must be examined to the full as closely with reference to the longitude as to the latitude of the spot where it was taken. It deserves special notice that the South Atlantic Ocean is much colder to the east of the meridian of 20deg. W. than to the west of it. All the isothermal lines take a sudden bend southwards in the neighbourhood of this meridian. This change in direction takes place even in summer, but at that season its place lies more to the westward, near the meridian of 25deg. W.

There is a cold current flowing northwards along the coast of Africa, and a warm current flowing southwards along the coast of Brazil; we find from the monthly charts that the Brazilian current, which we may consider as a southern branch of the equatorial current, splits into two parts in the neighbourhood of the parallel of 30deg. S. One portion flows in a south-easterly direction and loses itself, after throwing off several branches, in the polar current; the other portion flows by Patagonia and the Falkland Islands, and exerts such a warming influence on the climates of these countries in spite of their high southern latitudes that the numerous heads of black cattle, horses, and sheep which roam over the plains can find abundant nourishment even in the winter time. The south polar water which we see flowing past the Gulf of Guinea is warmed on its way; the coast line forces it to assume a westerly course, and it is to this source that we are indebted for the warm water which we find flowing in a northerly and southerly direction along the western shores of both oceans, and not to the Agulhas current, which can only send its waters during a few months of the year to the west of the south point of Africa. The very low temperatures found in the eastern portion of the ocean prove this statement completely. Between the meridians of 20deg. and 15deg. E. we see that the warm current shows itself very distinctly at lat. 35deg. S., while its influence is no longer noticeable as soon as we come to the northward of 33deg. S.

In order to afford as accurate information with reference to districts where the temperature varies much, as it was in their power to do, the Committee have authorized the publication of detailed extracts from the registers of captains who have noticed remarkable changes in the surface temperature. To these we will now draw attention. The first locality in which considerable alterations of temperature are met with is almost exactly on the equator, about the 23rd meridian of west longitude. At this spot in the month of July, Captain Code, in the "Orient," reports that the temperature fell 5deg., and rose again in the space of 24 hours, the water appearing of a light green colour. Similar observations have frequently been made in this region, and Captain H. Toynbee has drawn attention to them in a paper "On the Specific Gravity, Temperature, &c., of the Seas Between England and India," published in the proceedings of the Royal Geographical Society, in which he gives an account of seven successive observations of a temperature of 70deg. Fah. The observations were made in the same year as Captain Code's, and only three weeks later. The circumstance shows itself plainly in the Dutch charts for the month, with this difference, that the place where the mean surface temperature is lowest is on the parallels of 2deg. and 3deg. S., and between the meridians of 15deg. and 20deg. W. Admiral Sir F. Grey noticed very remarkable changes of temperature on the coast of Africa between the parallels of 10deg. and 20deg. S. in the month of May. He observed the surface temperature below 60deg. on two occasions when he was about 25 miles off shore, and he remarks, "It would appear that the temperature of the water decreases as we approach the shore." The charts show a striking discrepancy between the mean temperature of the square in question, which is 60·8deg., while that of the squares to the north and south of it are 76·3deg. and 62·2deg. respectively.

In the district bounded by the meridians of 10deg. E. and 40deg. E., and lying between the coast of Africa and latitude 50deg. S., most sudden and remarkable alternations of temperature are met with at all seasons of the year. Changes of temperature have been observed by some homeward-bound vessels between the parallel of 35deg. and the coast when crossing the Agulhas Bank, and Captain Toynbee remarks that the temperature of the water is a good guide to show whether you are on the bank or not. By far the greater number of the extracts refer to a region lying one or two degrees on either side of the 40th parallel of latitude. In the northern part of this belt the observations all fall to the eastward of the meridian of 10deg. E., but in the southern part it will be seen that in a few instances considerable alternations of temperature have been noticed as far west as the 8th or 9th meridian of east longitude.

Throughout the whole of this area the alternations of cold and warm water are most striking, and the changes of temperature are nearly as sudden and as great as those well known to be experienced on the northern edge of the Gulf Stream, where it is bounded by the Arctic current. The greatest actually observed has been a fall of 19·5deg. in one hour, recorded by Captain Major in the month of February. His position was in 41deg. 38min. S. and 21deg. 30min. E., and the surface temperature was observed to be 69·5deg. at 9 a.m., 50deg. at 10 a.m., and again 59·5deg. at noon. Captain Fitzsimons in October, in latitude 41deg. and longitude 21deg. E., noticed a decrease of temperature of 14deg. (from 67deg. to 53deg.) in one hour, while the ship passed through some heavy tide-rips. Captain Wherland in November, in latitude 39deg. 56min. and longitude 17deg. 20min. E., noticed an increase of 14deg. (from 53·5deg. to 67·5deg.) in two hours. In almost all the registers the fact of the sea being very high and confused is recorded, as well as the frequent occurrence of tide-rips or ripplings, and of great changes of colour in the water. Another region where sudden changes are noticed is off the coast of South America, from the 20th parallel of S. latitude southwards, and there are several well marked areas, notices of which will be found in the extracts from the registers. Colder water is to be met with off Rio Janeiro inside the line of soundings than outside. This would appear to show that the branch of the equatorial current of warm water which flows southwards along the coast of Brazil is usually unable to force its way into the shallow water on the bank of soundings, along which a narrow stream of colder water flowing northwards is met with. The difference is greatest in February, when it exceeds 4deg. However, in July and August the conditions are quite changed, for then the temperature outside soundings is lower than inside.

South of the parallel of 30deg. S. the changes of temperature which are noticed, though not so striking as those observed off the African coast, are yet very remarkable. The entire area in which the observations are made lies west of the meridian of 50deg. Between the parallels of 35deg. and 40deg. S. changes of temperature of 20deg. within 12 or 14 hours have been repeatedly observed, with great variations in the colour of the water. As regards the relation of the currents to the depth of the water, Captain James Gales states, "The warm water is on the bank of soundings, the cold along the edge of it." This is a marked difference to the state of things noticed off Rio Janeiro. However, this cold water forms only a narrow strip, for to the eastward again the water is decidedly warmer. When we pass the parallel of 40deg. S. the charts show that

the mean temperature in latitude 40deg. to 45deg. S. is higher between 50deg. and 55deg. W. than in either of the squares situated east or west of it. The mean annual difference of temperature is 1·8deg. to the eastward, and as much as 5·4deg. to the westward. One observer, Captain James Brack, cuts across this warm water in September going westward. In latitude 41deg. to 44deg. S. and longitude 54deg. W. he finds an increase of 13deg. in 14 hours, succeeded by a decrease of 14deg. in 10 hours. The same observer had previously passed through a cold current in latitude 40deg. S. and longitude 53deg. W.

Another area frequently referred to in the extracts is that bounded by the parallels of 45deg. and 50deg. S., and the meridians of 47deg. to 53deg. W. Here the differences of temperature are not very great, but there appears to be evidence of the existence of two currents, a cold and a warm one close to each other. The edge of a warm current is frequently noticed at about the 51st meridian between the above-named latitudes, while the cold current appears to extend, at least in lat. 49deg., from that meridian eastwards to that of 46deg. W., as many observers report a sudden fall of temperature about long. 47deg. W. Off Cape Horn a warm current close in shore has been commonly noticed. Captain Jas. Gales, in March, remarks, when the sea temperature rose 2·5deg., "Standing northward, and temperature of sea increasing. In dark or thick weather that increase in the temperature of the sea would be a hint to tack ship." The observation was taken about 40 miles south of Cape Horn. The whole of this coast of South America seems, even from the small amount of information which has been attainable relating to it, to present features of interest as regards the sea surface temperature observed along it, which are perhaps equal in importance to those of the Agulhas current. Several extracts are given tending to show how far the surface temperature is affected by heavy rain. It appears that in some extreme cases a fall in temperature of 4deg. or 5deg. may be attributable to the cooling action of a heavy fall of rain.

HOLMES' STONE-DRESSING MACHINE.

TO supersede manual labour in dressing stone by mechanical means has been for many years past the aim of Mr. J. E. Holmes, who has made this question his special study. The result has been the production of a machine in which the working tools are applied to the surface of the stone in the same direction and with the same effect as the chisel in the hands of the workman. A machine upon this principle, worked by hand, was described and illustrated by us at page 156 of our last volume. Since our notice of that apparatus, Mr. Holmes has improved some of its details, and has adapted it for working by steam power. The machine thus improved was inspected by us on Friday last on the Thames Embankment at Westminster, where it was at work. The apparatus consists of a travelling plate carrying the stone to be dressed beneath the cutters. These cutters are carried in a transverse bar, and consist of either a series of chisels or a single knife, according to the work to be done. The bar is actuated from a cranked axle, which imparts an oscillating motion to it, imitating very closely the action of a workman's hand and mallet. On the occasion of our visit, two blocks of Portland stone were provided, measuring about 6ft. in length by 21in. in width and 14in. in depth. One of these blocks had been dressed by hand by two workmen, who completed their task in sixteen hours. The other was dressed by the machine during our stay in two hours. The machine dressing was superior in finish to that done by hand, with the exception that an accidental notch in the blade caused a continuous ridge on one of the surfaces. A block of granite was afterwards placed in the machine, and dressed in a very short space of time, with an equally satisfactory result. We are glad to record the progress of mechanical invention in this direction, and to give Mr. Holmes credit for the production of a machine which appears destined to supersede stone dressing by hand. We may add that the machine was exhibited by Mr. Shearer and Mr. Freeman, on behalf of the Dalbeattie and of the Penryn Granite Quarries, the offices of which are at 21, Great George-street, Westminster.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.

THE successful completion of the submarine cables between Cuba and Florida, in 1867, appeared to open up at once a new field for telegraphic enterprise, and attention was called to the fact of the importance of the undertaking. So successful has telegraphic communication been between Havana and the United States, that a second cable was submerged last year, and we are assured that the revenue alone for these cables is £60,000 per annum, after eighteen months' working. Communication being thus established between America and the largest of the West India Islands, it became simply a question of time when the telegraph should be extended throughout the Islands. Under ordinary commercial circumstances, this would have of necessity followed in a few months, but the Cuba cables were laid at a time of great depression, and when telegraph schemes were little thought of; since then, however, times have changed for the better, and submarine telegraph enterprises are now looked upon with better favour than they ever were, within the last twelve months several millions of capital being found for the prosecution of but few schemes. It is now, exactly two years since the laying of the first Cuba cable, that a company has been brought out for the extension of telegraphy through the West India Islands and to Panama, and it is announced that "the company is formed for the purpose of extending telegraphic communication throughout the West India Colonies, and, at the same time, of forming the central link of the telegraphic communications of Brazil, Peru, Chili, Buenos Ayres, and the other States of South America, with London, New York, and the whole of the Continent of Europe and North America."

At the beginning of last year, in glancing at future telegraphic prospects, we remarked that "the extension of the telegraph from Cuba to Jamaica and Panama may be confidently looked forward to as one of the enterprizes of the year. The late successful completion of the Florida and Cuba cable has made this extension a necessity, the carrying out of which again will lead enterprize on to the South American continent, and bring us within easy communication with many important points." The extension foreshadowed by us and now proposed will consist of 2,550 miles of submarine cable, and 350 miles of land line, and "will commence at the Island of Cuba, and be continued through the West India Islands to the continent of South America, with a branch cable to Panama." Concessions have been obtained for a term of 40 years for establishing and working telegraph cables from Havana, through Cuba, to Porto Rico, Mexico, and Panama, and from Porto Rico to the continent of South America, through the chain of the West India Islands; and important rights, including subsidies (estimated at about £14,000 per annum have been obtained from the colonial governments of Jamaica, St. Thomas, Barbaboes, Trinidad, Demerara, &c. The proposed route of the line will be a land line through Cuba from Havana, the terminus of the American cable, to the coast, from whence a cable will be laid to Jamaica. This island will become an important point, for from thence a cable will be laid to Aspinwall, in Panama, and another to Porto Rico, thence to St. Thomas, Barbadoes, and Trinidad, to Surinam, on the north coast of the South American continent. The longest of these cable sections will be 600 miles, the principal being short.

Negociations are in progress for the extension of telegraphic communication to Peru, Chili, and the Argentine Confederation, and the "Brazilian Government are also taking active steps for the extension of the line from Surinam to Rio Janeiro, with stations at Bahia, Pernambuco, and other ports in the route, by which means the company will be in connection with lines now completed or in course of construction, from Rio to Buenos Ayres, Monte Video, and Valparaiso." The capital of the company is £650,000, in £10 shares, and a contract has been entered into with the India-Rubber, Gutta-Percha and Telegraph Works Company, for the sum of £587,000, to make and lay the submarine cable. The cable will be of the best quality and of the same class as the Cuba-Florida cable—a single conductor well insulated, sheathed with solid iron wires, and protected externally with hemp covered with a silicated bituminous compound.

The cables are to be constructed within eight and to be submerged within eleven months. The statements as to revenue are as favourable as prospectuses usually show, but there is sufficient information known to warrant the conclusion that the enterprise will be as remunerative as successful. The local amount of traffic in the West Indies may be calculated as considerable, added to which we have the business arising from transactions between the Islands and America and Europe, and, lastly, the large additional amount that may be expected from the various commercial relations with the countries of South America. Our communications with the United States are firmly established, telegraphic extension is largely on the increase in South America, and, when by inserting the middle link in the chain of telegraphic communication by establishing these West India cables, uniting telegraphically North with South America, we may expect a very large amount of business.

The manner in which the India-Rubber, &c., Company manufactured the Cuba cables gives every promise that the proposed cable will be equally successful, and, with the amount of appliances at their command at Silvertown, we may fairly hope to see an excellent cable. The various submarine cable works are now busily engaged in manufacturing large amounts of cable, and, in the interest of submarine telegraphy, we shall be glad to see the machines at Silvertown hard at work. The Company is brought out under favourable auspices, the direction is solid, and we trust to hear that the Company have obtained the necessary capital for an enterprise that must sooner or later be carried out.

A CIRCULAR FROM THE GAS REFEREES.

THE last dodge (there is no other word for it) of the gas referees, unlike many of their proceedings, displays remarkable cuteness, and, indeed, indicates a praiseworthy desire on their parts to become acquainted with the details of the manufacture of gas. They have addressed a circular to the country gas companies, asking for information. They wish to know as follows:—

1. Description and name of coal used.
2. Amount of gas realized from one ton of coal.
3. Quantity of gas annually made.
4. Greatest daily make in winter.
5. Illuminating power of the gas produced.
6. What apparatus is used for ascertaining the illuminating power.
7. Description of material used for purifying the gas from sulphuretted hydrogen.

8. Means adopted for freeing the gas from ammonia.
9. Number of purifiers in use, with their size.
10. Number and size of scrubbers.
11. What liquid is used in them.
12. What number of grains of sulphur per 100ft. is left in the gas.
13. By what apparatus is this ascertained.
14. What number of grains of ammonia per 100ft. is left in the gas.
15. By what means is this ascertained.

Now, the three "competent and impartial" gentlemen who have just sent out this circular, have to prescribe how three London companies are to purify their gas, and if some country engineer will kindly inform them what to prescribe, both they and the companies will be greatly obliged to him. We see some proceedings analogous to this occasionally in the medical papers. A doctor has a case he does not know how to cure, and he writes to ask if any of his professional brethren can tell him how to do it. The proceeding is candid, as a confession of ignorance; but the wrong party gets the fees and the credit of the cure. If anything comes of this circular, it will be some country engineer who has taught the referees and the companies what they ought, and are supposed, to have known. When replying to these questions it must be remembered that information supplied to a public board is public property; and, as soon as Parliament re-assembles, a motion will be made for the publication of the answers.

THE MELBOURNE MINT.

A ROYAL proclamation has just made its appearance, legalizing gold coins which may be hereafter issued from the above-named establishment. The document has certainly been published in good time, for the mint in question does not, as yet, exist, and is not likely to do so before the end of 1870! It is to be hoped, moreover, that the Melbourne coins, when they do appear, will prove to be superior to the unhappy specimens of mintage which have resulted from the Sydney presses. The Australian sovereigns and half-sovereigns at present in circulation are quite unworthy the honour of intermingling with those of Great Britain. They are badly designed, imperfectly struck, soft, brassy in appearance, and well calculated to incite activity among counterfeit coiners. There is no good reason why the gold coins struck at the branch mints of Sydney and Melbourne should not bear the Imperial stamp upon their surfaces. If it be necessary to give them a distinctive character at all from the pieces struck at Tower-hill—which is doubtful—a small letter, S or M, indicating Sydney or Melbourne, as their birthplace, might readily be imprinted upon them. It is of the highest importance that our gold currency should possess the characteristic of uniformity of design. The Sydney coins violate this wholesome rule, and it is to be feared that the Melbourne money will—unless strong protests be entered against the perpetration of such a blunder—increase the irritating nuisance. It is to be hoped that the Governments, British and colonial, will interpose and prevent so flagrant an act fo folly being consummated.

NOTES ON RECENT SCIENTIFIC DISCOVERIES, AND THEIR PRACTICAL APPLICATIONS.

THE PROTECTION OF IRON SHIPS—A REPORTING MACHINE—A NEW PYROMETER.

THERE is nothing novel in the idea of preventing the oxidation of iron ships by the use of zinc. Several modes of applying the zinc have been suggested by various inventive minds, but, for some reason or other, shipowners still rely on paint to preserve their ships, and do not seem to have faith in the protective power of electrical action. The latest invention for the protection of iron ships by this means is that of MM. Demance and Bertin, who distribute about the inner side of the shell, tubular reservoirs, made of zinc, which are riveted to the plates, to place the metal in perfect communication with the iron hull. These reservoirs are charged with sea water, which is changed every day. Bands of zinc carried in all directions over the inner side of the hull connect the various reservoirs, and strips are here and there brought to the outer side, and made to communicate with the sea. We need not here explain the action which takes place. If the authors can be relied upon, the success obtained is perfect. Experimental boats kept in very salt water for a year, they say, do not exhibit a trace of oxidation in any part.

A "stenographic press" has been invented by M. Gensoul. The reporter sits at something like the keyboard of a pianoforte, and by applying his fingers to the keys, prints the words as they drop from the lips of the speaker, syllable by syllable, on a strip of paper which rells along underneath. When we say this, we do not of course mean that the words are printed in letters. The keyboard appears to be divided into three parts of eight keys each. The left side, worked by the four fingers of the left hand, prints signs which represent initial consonants; the right, worked by the fingers of the right hand, prints final consonants; and the middle, acted on by the two thumbs, prints the mediam vowels. We gather that something like a phonetic system of signs is employed. A few months' practice is said to enable any operator to follow the most fluent speaker with ease. We ought to say that M. Gensoul's system renders it unnecessary to transcribe the copy. Just as with the phonetic system, if legibly written, the compositor can set up the speech in common type, from the printed strip furnished by the machine. As to the comparative ease of writing characters with a pen, and printing them in the way here described, we can give no opinion. What we should certainly miss, if the machine came into use in the galleries of our Houses of Parliament, would be the happy skill with which the reporters condense the speeches from their notes. We have very few speakers who could bear to be reported by a machine.

Everybody knows the difficulties which stand in the way of exactly estimating high temperatures. The best pyrometers we have had hitherto can only be supposed to give approximate results, and some of them may be very wide of the truth. We notice, then, with pleasure, one devised by M. Lamy, which shows within two or three degrees Centigrade the temperature of a furnace gradually heated up to redness, and gives its indication at a distance from the furnace, so that at a porcelain factory, for example, a manager can sit in his office and see the temperatures of all the furnaces in his establishment. The instrument is as simple as it seems to be efficient. It is merely an iron retort, containing marble, the neck of which communicates, by means of a narrow tube, with a needle moving over a dial plate. As the heat rises, the marble is decomposed, and carbonic acid is set at liberty. A special contrivance measures the tension the gas arrives at, and as this has a direct relation to the temperature, the measure of the one is made the measure of the other. Up to a certain point, we have little doubt this instrument may be relied upon.

PARLIAMENTARY NOTES.

IN the House of Commons yesterday week, Mr. Bentall (in the absence of Mr. Howard) asked the Under Secretary of State for the Colonies if his attention had been directed to the new Patent Law Act passed by the Senate and House of Representatives of Canada, and to which the Governor General gave his assent on the 22nd of June last; if he was aware that by the terms of this Act the rights hitherto enjoyed by British subjects and foreigners were abolished, and that, unlike the patent laws of England and all other countries, the benefits of its provisions were limited to persons permanently resident in its own dominion; and whether the Colonial Office was prepared to recommend the Government to advise her Majesty to withhold or postpone her assent to the bill, with a view to give an opportunity to the Canadian Legislature to reconsider its provisions.

Mr. Monsell was understood to say that they had received no copy of the Act, and for the reason that this Government had no power to approve or disapprove of the law. It appeared to be an assimilation of the different laws on the subject of patents that had formerly existed in the colonies of Nova Scotia, Canada, and New Brunswick. Mr. Monsell's reply is discussed by Mr. Fordred in our "Correspondence" columns.

Mr. Macfie said that next session he would call the attention of the House to the propriety of having at the Colonial Office a set of all the Acts of the colonial parliament.

On Friday, Mr. Muntz asked the Secretary of State for War if it was intended to proceed with the manufacture of the Martini-Henry rifle otherwise than for trial; and if he was aware that very great doubts were entertained by competent parties as to the durability of the mechanism of the presumed improvement.

Captain Vivian said that it was not intended to proceed with the manufacture of the Martini-Henry rifle till they had been tested in the hands of the troops; therefore, 200 rifles would be distributed among small portions of the troops quartered in various parts of the world, so that the efficiency of the weapon might be tested in all ways and circumstances. As to the second part of the hon. gentleman's question, the authorities were not aware of any doubts as the permanency of the weapon, and those whose duty it was to test it saw no reason to entertain such doubts.

Lord Elcho asked if any tests were to be used for the cartridge as well as for the rifle.

Captain Vivian said that it was intended to apply further tests to the efficiency of the cartridge, so as to obtain the best possible cartridge for the rifle.

At the same sitting, Mr. Childers brought forward a motion on the subject of the transit of Venus. He observed that in 1874 there would be an opportunity of observing or ascertaining one of the most remarkable experiments that could be made. The only method of ascertaining the distance between the sun and the earth, or, more correctly speaking, the horizontal parallax, was by observing the transit of Venus across the sun's disc. That transit would occur in the year 1874, and astronomers were most desirous that the utmost care should be taken in observing this remarkable event. The Admiralty had been at pains to ascertain the expense of the observation in the various parts of the world where it would be seen. They had come to the conclusion that it would cost £10,500, to be spread over five years, and as this was a prospective vote they had thought it better to ask the consent of the House at once, as the expenditure would go on for some years. The amount was small, and the object to be gained was of great value. He, therefore, moved that a humble address be presented to her Majesty, praying that her Majesty would be pleased to direct that steps should be taken for making the observation of the transit, and assuring her Majesty that this House would make good the same. The resolution was agreed to.

On Monday last, on the order for the second reading of the Steam Boilers Inspection Bill, Mr. Sheridan said it would be impossible to proceed with the measure this session, but as he would reintroduce it next year he might state briefly what its object was. The bill proposed a system of registering and testing steam boilers as they came from the manufacturer. That process would be very easy and simple, and it could be conducted very inexpensively, and the advantage to be gained would be found in the larger number of boilers which would then be sold in consequence of the increased confidence which the public would have in them. The bill also proposed that there should be a periodical inspection of the boilers, and accidents from boiler explosions would necessarily be very much diminished by that. Within the last ten years 500 persons had been killed by boiler explosions, and he believed that by a proper systematic inspection a great portion of the mortality might have been avoided. The hon. member concluded by moving that the order for the second reading of the bill be discharged.

Mr. Bazley said he hoped that during the recess the Government would take that subject into their consideration, with the view of preventing, as far as possible, these explosions.

Mr. Bruce said the subject had not escaped the consideration of the Government, but it was one with which it would be very difficult to deal satisfactorily. The accidents from boiler explosions were usually of a most frightful description, and in number they nearly equalled those which took place in coal mines. The average number of the latter was about 100 a year, while the average number of the former amounted to about ninety

a year; so that there was but little disparity in their magnitude. It would, however, be very difficult for the Government to establish a system of inspection of all the boilers in the country. One of the deputations that had waited upon him in reference to the subject had recommended that whenever an inquest was held upon the remains of any individual who had lost his life in consequence of one of those explosions, some skilled person should be present for the purpose of assisting the jury. Another deputation recommended that whenever death ensued from the negligence of the owner of a boiler, he should be compelled to make some compensation to the relatives of the sufferers. That was a matter, no doubt, deserving of consideration, but it was one which could not be considered alone, because the same principle would apply to all other employers who had been guilty of negligence leading to a similar result. He would engage to give his consideration to the subject during the recess, with a view to provide for the evil the best remedy he could devise.

The order for the second reading of the bill was then discharged.

PATENT ONE-SHAFT LOOM.

BY MESSRS. MOORE AND GADD.

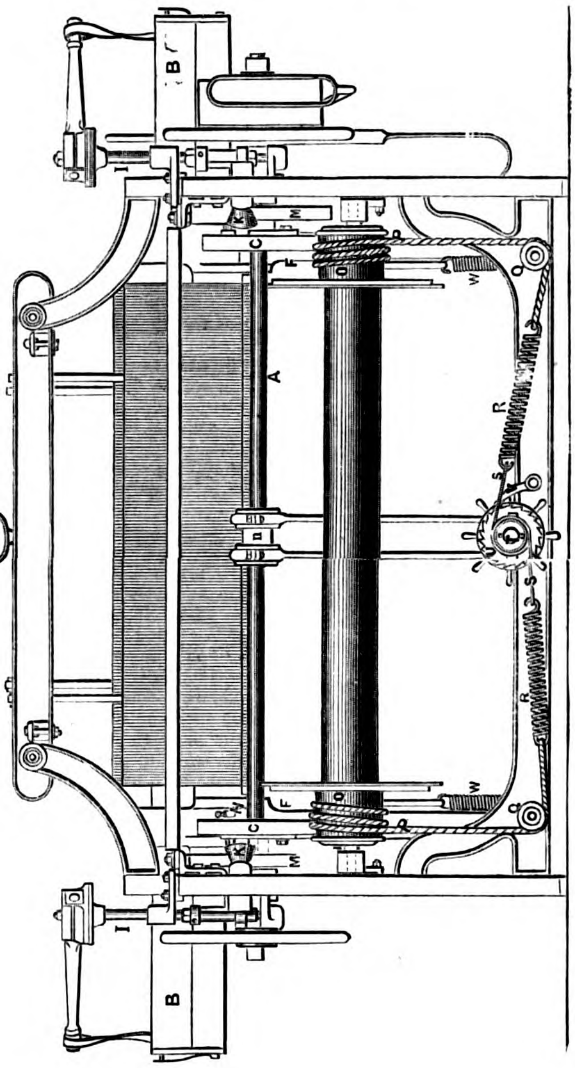


FIG. 2

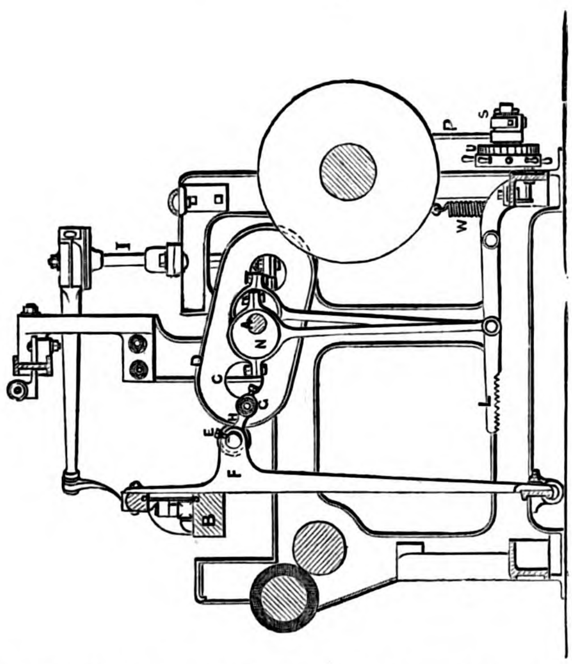

FIG. 1

MOORE AND GADD'S PATENT ONE-SHAFT LOOM.

WE recently gave a brief description of a new power loom, by Messrs. Moore and Gadd, two of which we saw at work in Brown-street Mill, Salford, others, to the number of about a hundred, being at work in the various mills. We now illustrate this apparatus in the accompanying engraving, in which fig. 1 is a cross section and fig. 2 a back elevation of the improved loom. It will be observed that instead of the ordinary crank for driving the sley a peculiar double cam is used with a drag link. In our engraving, A is the main driving shaft, B is the sley, and C is a cam mounted on the shaft A, and suitably formed to impart the desired motion to the sley. The shaft A revolves at one-half the ordinary speed, that is to say, the loom makes two picks during one revolution of the shaft, the cam C causing the sley B to perform two complete strokes during one revolution of the cam. The cam C is formed with a flange D, the outer surface of which operates upon an anti-friction bowl E, revolving on a pin fitted in bearings formed in the sley-sword F. The inner surface of the flange operates upon a second anti-friction bowl G, revolving upon a stud fixed to the radius or drag link H, the link oscillating to some extent around the centre of motion of the bowl E as the cam revolves, in order that the bowl G may accommodate itself to the movement of the cam. As the cam C revolves, the bowls E and G are acted upon alternately, and the sley B is caused to vibrate, moving forwards to beat up the weft when the bowl E is acted upon, and backwards, to admit of the passage of the shuttle when the bowl G is acted upon. The form of cam shown in the engraving is such as will impart a movement to the sley similar to the movement which would be imparted to it by a crank and connecting rod acting in the ordinary manner. The picking shafts I I are actuated by tappets fixed upon the shaft A, and acting on the arms K K of the picking shafts. The healds are actuated by the levers L L, a vibrating motion being imparted to the levers by means of the eccentrics M M, mounted on the shaft A. It will be seen that as each one of the two bowls revolves constantly in the same direction when the loom is at work, greater smoothness of action is attained, with less wear of the bowls and cam, than when only one bowl is used to each cam.

The tension of the warp is regulated by the apparatus next to be described. The warp beam is fitted at each end with an ordinary drum or pulley O O, upon which the ropes P P are coiled, one end of each rope being attached to a spiral spring R, the other end, after being passed partly around the carrier pulley Q, which revolves on a stud fixed to the rail, being attached to the end of the spiral spring W. The ratchet wheel U is mounted on a stud fixed to the rail, and is formed with a long boss T, to which the ends of the straps S S are attached, the opposite ends being connected with the spiral springs R R. When the ratchet wheel is rotated in one direction the straps S S will be wound upon the boss or pulley T, and the two springs W W will be simultaneously extended to an equal extent, and thereby the ropes P P will be tightened upon the pulleys O O, and the tension of the warp will be increased. A contrary effect is produced by rotating the ratchet wheel in a reverse direction.

The method of operating with the apparatus is as follows, viz.:—When a full warp beam has been placed in position in the loom, and the ropes, springs, and straps connected together, the ratchet wheel is rotated until a suitable amount of tension is imparted to the warp, and the strain upon the ropes P P is maintained so long as is desirable by the pawl V preventing the backward rotation of the ratchet wheel. At such times during the process of weaving as it may be thought desirable to reduce the strain upon the ropes P P, the pawl V is raised out of gear with the ratchet wheel, and the wheel is allowed to rotate to some extent in a reverse direction, and the pawl is then placed in gear with the ratchet wheel, and the strain upon the ropes thus reduced is maintained until it is thought advisable to effect a further reduction in the strain.

It is important to know that the improved loom runs very much lighter than the ordinary loom.

Upon the discovery of this fact it was decided to ascertain the exact amount of power required to drive one of the new looms as compared with one of ordinary construction. A series of dynamometrical experiments were therefore carefully made by Mr. Edward K. Dutton, C.E., of Smithy Door, Manchester, to whom we are indebted for the following interesting report thereof. To ensure correctness, and to give the results their proper value, a loom was obtained, made from the same patterns and by the same makers as the improved loom, and differing only in those parts affected by Messrs. Moore and Gadd's patents, both looms having 45in. reed space. A No. 28 warp, 40in. wide, was put into each loom, the work to be performed being thus equal in amount.

The apparatus employed was specially constructed, an ordinary dynamometer being ineffectual for the purpose. A heavy flywheel, with its axis running on anti-friction rollers, was fitted at one end with a pulley to drive one of the looms, and at the other with a differential motion, consisting of four mitre wheels, the arrangement being similar to that of a lever dynamometer, with the exception that instead of the intermediate wheel and lever a circular pulley carrying two intermediate wheels was employed. A scale pan was suspended from a strap attached to the circumference of the pulley. This apparatus has been found to be very sensitive, so that when the engine has been running steadily the weight required to drive either loom could be ascertained within two ounces. The diameter of the strap pulley was 10¾in., and the radius from the centre of the intermediate wheel to the centre of the strap from which the weights were suspended was 6¾in. The weight suspended when the apparatus was running without driving either of the looms was 7½lb. The result of ten tests is given in the following table:—

Number of Test.	Date.		Description of Loom.	Number of Picks per minute.	Speed of Strap Driving Dynamometer.	Speed of Strap Driving Loom.	Weight held in Suspension in lbs.	Horse Power to Drive One Loom.	Saving in Power per cent. as compared with Test 8.

REMARKS:—

No. 1. Loss of power through the pulley driving loom chafing against framing.

No. 3. Loom not working satisfactorily; defect afterwards found out and rectified.

No. 6. Loom considered by attendant to be working well.

No. 8. This gives the best result obtained during two hours' working. In order that the patent loom should have no advantage, an independent man, experienced in loom adjustment, was obtained to mind the loom during this test, and to adjust the same, and after making all the bearings and working parts as free in their action as possible, the weight required to drive was reduced to the point given in the table.

No. 9. The ordinary loom would not work at this speed, so no corresponding test could be obtained. The calculated speed was 240 picks, but, owing to the straps being only 1¼in. wide, there was much slip and, of course, loss of power.

These experiments show, that owing to the great increase in the amount of power required to drive looms, as the speed of the looms is increased, any increase above a fair working speed will be of doubtful advantage. For this width of loom 200 picks may be considered as the maximum of speed which may be attained with advantage. Further experiments would fix this with more exactness. Taking the best result obtained from the ordinary loom, viz., No. 8, for comparison, it is found that the patent loom shows a saving in power of 25·5 per cent., when making four picks less than the ordinary loom, of 24·7 per cent. when making two picks less, and of 19 per cent. when making two picks more. A comparison of these figures gives a calculated result of about 22 per cent. saving in power when both looms are making 178 picks per minute. It will be observed that the driving strap of the old loom moved with double the velocity of that of the new loom. This was an advantage to the old loom, so far as slip of straps was concerned. It is satisfactory to us to be able to state that in addition to these great recommendations the loom possesses yet another—that of being nearly 20 per cent. cheaper than the old one. This, combined with the saving of power, makes the invention very valuable, and must, we think, lead to the general adoption of this loom by manufacturers as circumstances admit.

ON THE THERMAL ENERGY OF MOLECULAR VORTICES.*

By W. J. MACQUORN RANKINE, C.E., LL.D.

IN a previous paper presented to the Royal Society of Edinburgh, in December, 1849, and read on the 5th of February, 1850, the author deduced the principles of thermodynamics, and various properties of elastic fluids, from the hypothesis of molecular vortices, under certain special suppositions as to the figure and arrangement of the vortices, and as to the properties of the matter which moves in them. In subsequent papers, he showed how the hypothesis might be simplified, by dispensing with some of the special suppositions. In the present paper, he makes further progress in the same direction, and shows how the general equation of thermodynamics, and other propositions, are deduced from the hypothesis of molecular vortices when freed from all special suppositions as to the figure and arrangement of the vortices, and the properties of the matter that moves in them, and reduced simply to the following form: that thermometric heat consists of a motion of the particles of bodies in circulating streams, with a velocity either constant or fluctuating periodically. This, of course, implies that the forces acting amongst those particles are capable of transmitting that motion.

The principal conclusions arrived at are the following:—

1. In a substance in which the action of the vortices is isotropic, the intensity of the centrifugal pressure per unit of area is two-thirds of the energy due to the steady circulation in an unit of volume. The centrifugal pressure is the pressure exerted by the substance in the perfectly gaseous state.

2.* If there be substances in which the action of the vortices is not isotropic, then in such substances the proportion already stated applies to the mean of the intensities of the centrifugal pressures in any three orthogonal directions.

3.* The proportion which the whole energy of the vortices, including that of the periodic disturbances, bears to the energy of the steady circulation alone, may be constant or variable.

4. Absolute temperature is proportional to the energy of the steady circulation in unity of mass, and to the specific volume in the perfectly gaseous state.

5. In substances which are nearly in the perfectly gaseous state, experiment shows the proportion in which the whole energy exceeds that of the steady circulation to be sensibly constant; and its value may be found by computing in what proportion the dynamical value of the specific heat at constant volume exceeds once and a-half the quotient found by dividing the product of the pressure and volume by the absolute temperature. *The following are examples:—air, 1·634; nitrogen, 1·630; oxygen, 1·667; hydrogen, 1·614; steam-gas, 2·242.

6. The known general equation of thermodynamics is deduced from the hypothesis of molecular vortices,* freed from the special suppositions made in the paper of 1849-50.

The new conclusions obtained in the present paper are marked *. Those not so marked were arrived at in the paper of 1849-50.

[The general equation of thermodynamics is here stated for convenience; let dQ be the thermal energy which must be given to unity of mass of a given substance, in order to produce a given indefinitely small change in its temperature and dimensions: then— $dQ = \tau\, d \cdot \phi$;
in which τ is the absolute temperature, and ϕ the thermodynamic function. The value of that function is—

$$\phi = Jc \operatorname{hyplog} \tau + \chi(\tau) + \frac{dU}{d\tau};$$

Jc being the dynamical value of the real specific heat; U, the potential energy of the elasticity of the body at constant temperature; and $\chi(\tau)$, a function of the absolute temperature, which is null or inappreciable in a substance capable, at that temperature, of approximating indefinitely to the perfectly gaseous state, and is included in the formula, in order to provide for the possibility, suggested by Clausius, that there may be substances which have not that property at all temperatures].

* Abstract of a paper read before the Royal Society of Edinburgh, May 31, 1869.

THE MANCHESTER STEAM USERS' ASSOCIATION.

THE last ordinary monthly meeting of the executive committee of this association was held at the offices, 41, Corporation-street, Manchester, on Tuesday, June 29, 1869, Mr. William Fairbairn, C.E., F.R.S., LL.D., &c., President, in the chair, the previous meeting having been held on Tuesday, June 1, Mr. Charles Heaton, of Bolton, in the chair. On both these occasions, Mr. L. E. Fletcher, chief engineer, presented his usual report, but on account of the amount of business before the committee on the first occasion the meeting was adjourned, and, therefore, an abstract is now given of his report for the past two months. During that time 446 visits of inspection have been made, and 934 boilers examined, 558 externally, 11 internally, 4 in the flues, and 361 entirely, while, in addition, 6 have been tested by hydraulic pressure. In these boilers 438 defects have been discovered, 13 of them being dangerous. Furnaces out of shape, 14; fractures, 73—1 dangerous; blistered plates, 31—1 dangerous; internal corrosion, 53; external ditto, 66—5 dangerous; internal grooving, 60—2 dangerous; external ditto, 2; feed apparatus out of order, 1; water gauges ditto, 6; bow-out apparatus ditto, 9—1 dangerous; fusible plugs ditto, 2; safety valves ditto, 4—2 dangerous; pressure gauges, 36; boilers without glass water gauges, 15; ditto safety valves, 1—dangerous; ditto pressure gauges, 14; ditto blow-out apparatus, 19; ditto feed back pressure valves, 32. On the present occasion, Mr. Fletcher reports nine explosions, by which 26 persons have been killed and 45 others injured. Eight of these explosions occurred to boilers not under the inspection of this association, while the ninth, which was only of a minor character, consisting of the collapse of a furnace crown, and by which fortunately no one was either killed or injured, occurred to a boiler under the inspection of this association. The following is a statement of explosions, from April 23, 1869, to June 25, 1869, inclusive:—April 29, double-furnace, water tube, internally fired; May 12, particulars not yet fully ascertained, 1 killed, 1 injured—total, 2; May 13, plain cylindrical, for steaming rags, no fire, 1 killed, 2 injured—total, 3; May 29, plain cylindrical, egg-ended, externally fired; May 31, plain cylindrical, flat-ended, externally fired, 4 killed, 4 injured—total, 8; June 9, two-flue "Lancashire," internally fired, 15 killed, 33 injured—total, 48; June 14, single-flue or Cornish, internally fired, 1 injured—total, 1; June 16, plain cylindrical, egg-ended, externally fired, 3 killed, 1 injured—total, 4; June 23, single flue or Cornish, internally fired, 2 killed, 3 injured—total, 5. Total—26 killed, 45 injured.

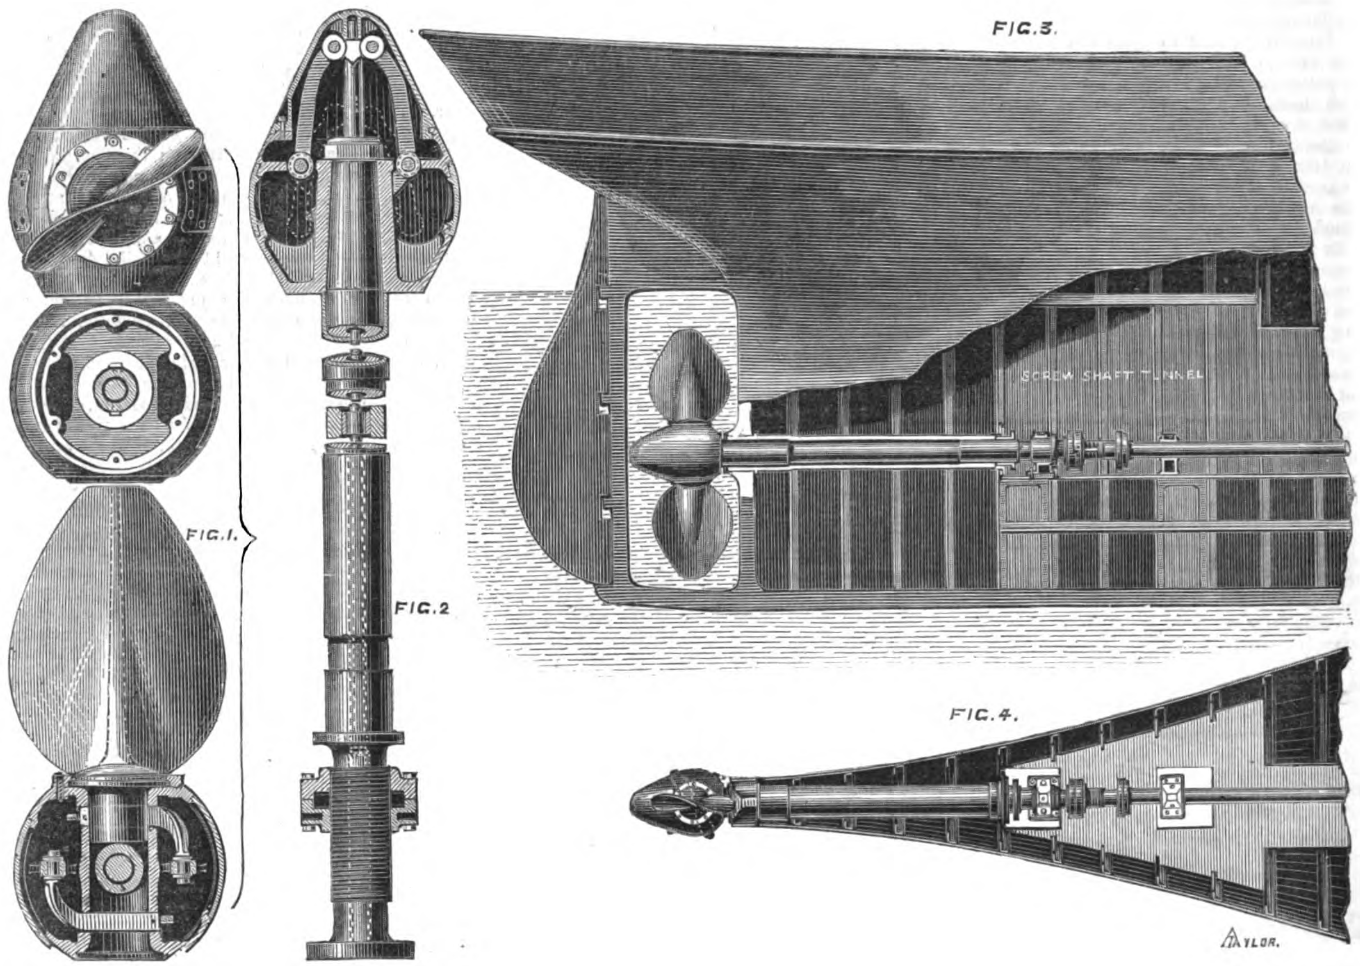
Mr. Fletcher's report contains some interesting remarks upon the subject of the overheating of furnace crowns and other boiler plates when covered with water, which will appear in our next issue.

HARRISON'S SYNCHRONOUS CLOCKS.

IN a notice of the exhibits at the last conversazione of the Institution of Civil Engineers, and which appears at page 398 of our last volume, we described Mr. Harrison's synchronous clock. Since the time of our notice, a committee has been formed to thoroughly test their principle, and during the past week several clocks were exhibited at the British Horological Institute, Northampton-square, and gave considerable satisfaction to those who examined them. Although we have already described this invention, it may not be out of place here briefly to recapitulate its main points. The advantages claimed for Mr. Harrison's clocks are that they will be corrected for any error, fast or slow; that the hands are set by the motive-power of the clock, and not by the electric current, as formerly. By this arrangement, great power can be obtained to insure its perfect action, while the discharging force of the current may be feeble or strong. No electrical break in a line of clocks, however distant or numerous, is required, thereby obviating the difficulties arising from oxidation of contact points. By a special arrangement of the mechanism, residuary magnetism is impossible. In the striking clock, the first blow of the hour will be given within a single beat of its pendulum to the true time. These clocks may be powerfully constructed, and used with either weight or spring, and with any length of pendulum; it will not be necessary to open the cases for any purposes but repairs. Any person can wind them, thus dispensing with the clock-maker, except for repairs.

BEVIS'S FEATHERING SCREW, AS FITTED TO THE "KATHLEEN."

BY MESSRS. LAIRD BROTHERS.



BEVIS' FEATHERING SCREW.

AT page 206 of our last volume we noticed a new feathering screw by Mr. R. R. Bevis, which had been introduced by Messrs. Laird Brothers in the "Kathleen" yacht, built for the Marquis of Downshire. We now give an engraving and detail particulars of this invention. It has long been thought that an efficient means of altering the pitch or feathering the blades of a screw in a fore and aft direction would be a great advantage to screw steamers, rendering them less dependent on their steam power, by making them faster and more handy under sail, as a screw of the ordinary kind, whether fixed or revolving, is a heavy drag against speed and handiness for sailing, and a lifting screw is somewhat complicated and costly. Mr. R. R. Bevis, managing engineer to the firm of Messrs. Laird Brothers, of Birkenhead, has patented the arrangement for effecting this object, which is free from many of the objections which have been made to feathering screws previously tried. The gear for feathering the blades is well protected, being worked in the screw-shaft tunnel by a sliding rod passing through the centre of the shaft, and the levers that move the blades are enclosed within the boss of the screw propeller. This system will be admirably adapted for ships of war or sailing ships with auxiliary power, where it is as important to have a good result under sail alone as under steam; and we fully expect that it will soon be applied to vessels of this class.

The result of its application to the "Kathleen" has been most satisfactory, as it was found on the trial trip that the blades of the screw were readily varied in pitch or feathered into a fore and aft line, and when so feathered the advantage in speed and handiness under sail was very marked. This has been fully borne out by the trials made on the voyage to the Mediterranean, during which, when the wind was favourable, the blades of the screw were feathered, and sail made, and on the wind falling light the blades were set at a suitable pitch and steam put on. The engineer reports the gear for feathering to work easily and without trouble, and that he can feather the blades in two or three minutes from the time of stopping the engines. The "Kathleen" flies the burgee of the Royal Yacht Squadron, and is of the following dimensions:—Length between perpendiculars, 140ft.; width, 22ft.; tonnage, 326 tons. She is fitted with a pair of inverted cylinder surface condensing engines of 60-horse power, and has capacity for about 70 tons of coal in her bunkers, and burns about five tons a day at a speed of nine knots. Messrs. Laird are now fitting two pairs of 150-horse power engines with screws on this system.

In our engraving, fig. 1 shows the boss of a screw with one blade and the levers by which the blades are moved. Fig. 2 shows the hollow stern shaft with sliding rod and crossbar, and the nut on the shaft by which the sliding rod is moved from inside the ship, and the mode of attaching the same by links to the levers within the boss to the shanks of the blades. Figs. 3 and 4 show the elevation and plan of this apparatus as applied to the yacht "Kathleen." The plain lines show the blades feathered into a fore and aft position for sailing, and the dotted lines as it would be when set to a pitch for steaming.

M. GIFFARD'S CAPTIVE BALLOON.

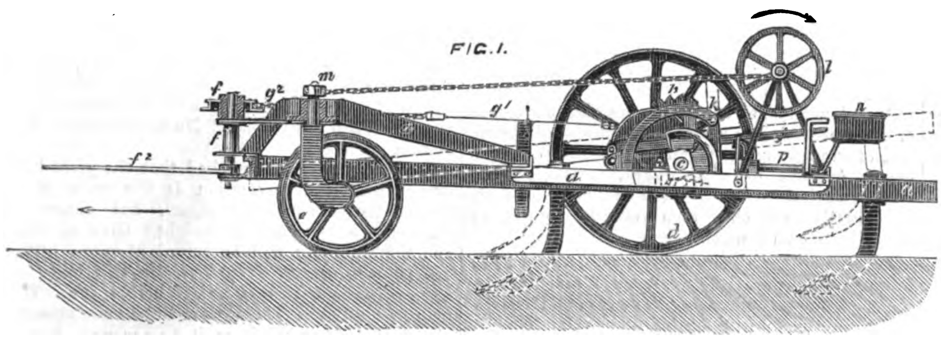
THE captive balloon at Ashburnham Park Chelsea, is again in working order, as, in fact, it has been for some time past. This balloon was fully described by us on page 361 of our last volume; we also subsequently recorded its untoward flight into Buckinghamshire on the afternoon of May 25. Since its re-capture it has undergone a thorough overhauling, which was rendered necessary by the damage it sustained from the trees among which it descended. It is now in excellent working order, and may be seen daily in fair weather high above the earth, with a car of scarcely perceptible observers. It was an unfortunate thing for the *prestige* of this splendid machine that it should have broken away as it did, and the circumstance is more annoying in that it arose from a preventible cause. It will be remembered that the balloon was ascending at a considerable angle, and the rope slipped over the flange of the main pulley, upon the edge of which it was cut. The simple addition of a guide block would have prevented the rope leaving the pulley. This addition has now been made, and ensures the perfect safety of the rope at any angle. We made another ascent in the captive balloon a few evenings since, in company with several ladies and gentlemen, all of whom thoroughly appreciated the pleasure afforded by a survey of the country at a height of 2,000ft. from the ground. We are glad to find that although confidence in the balloon was shaken at the time it made its escape, yet it has since been restored, and that the public are taking advantage of an opportunity seldom offered of seeing a really beautiful panoramic view of London as it lies spread out beneath them, with the surrounding country stretching away for miles. We were informed at the time of our ascent, that the evening previously, an old lady residing in Chelsea, and who had attained the remarkable age of 100 years and 2 days, made the ascent in company with a medical man. She enjoyed it greatly, and drank success to the enterprise in a glass of wine, when the balloon had attained its maximum height. This circumstance should encourage the timid to take a turn in the balloon, the view from which will amply repay them. MM. Godard and Aymo, the two experienced aeronauts, continue to have charge of the ascents, the management generally being under the superintendence of M. Yon.

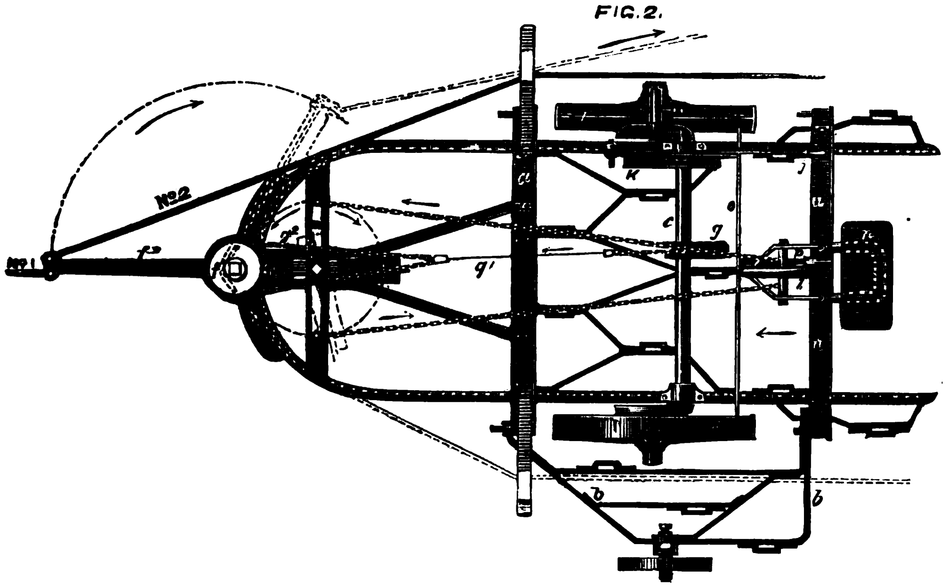
THE GASOPHANER.

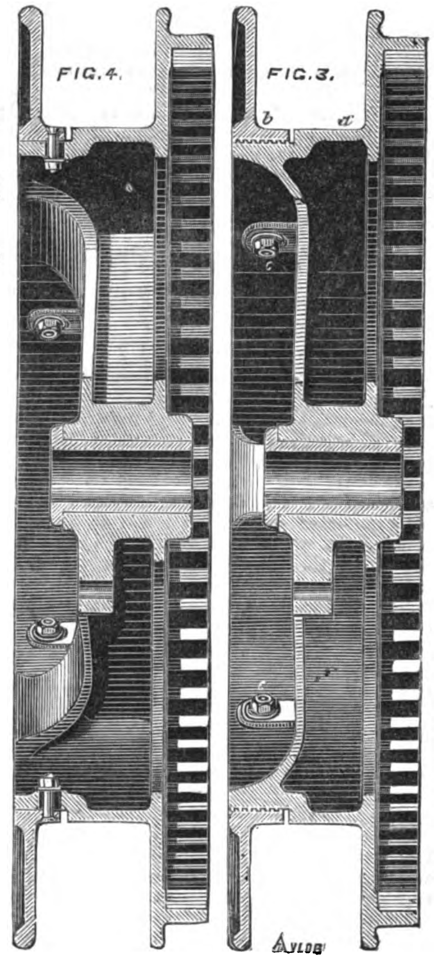
THE "Pioneer" states that a discovery has been made by an officer which, if the results on a large scale are at all commensurate with the experiments made on a small one, may prove of great value in giving a timely indication of the approach or presence of that poisonous state of the atmosphere which is generally believed to precede cholera and other epidemic diseases. The gasophaners, or poisonous gas indicators, as the discoverer calls them, are easily and cheaply made. A piece of fused

STEAM CULTIVATING MACHINERY.

BY MESSRS. FOWLER AND CO.







boracic acid, the size of a walnut, from which the water of crystallization has been expelled, is heated to redness in chlorine, or has dissolved in it while hot a small quantity of common salt, care being taken that there is not sufficient soda—16 per cent.—to convert the boracic acid into borax, which would spoil the effect. The red-hot lump of boracic acid thus charged is blown with a common glassblower's tube into a thin glass ball or bulb, about the size of a small hand lamp shade, and the gasophaner is ready for use. When first made, the glass is clear, with beautiful iridescent colours, due partly to the thinness of its sides; but left for a time, shorter or longer, according to the amount of moisture in the atmosphere, in normal breathing air, it becomes covered or clouded with a light blue film (due chiefly to the carbonic acid gas of the atmosphere), which, combined with the iridescent colours beneath, has an opaline or pearly lustre. On bringing the clouded gasophaner carefully to the flame of a spirit lamp, this film instantaneously vanishes, leaving the glass of that part again clear and shining. The delicacy of this test is so great that, although by breathing on the newly-made glass, the film may be much more rapidly formed than by mere exposure to the atmosphere, an approach to the spirit lamp flame will no longer drive off the carbonated compound formed, on account of the impure gases contained in the breath. At the same time, carbonates thus formed from the breath of a child, or of an extremely healthy person, vanish precisely as the aerial ones do on application of gentle heat. Held over a solution of ammonia, the air carbonate will not form, except on the upper part, where the ammoniacal gas has less action; but if held so that the breath may mix with the ammoniacal gas, a thick white cloud of carbonate of ammonia without opaline lustre, covers the gasophaner. This cannot be driven off by heat, but froths up on an approach being made to the lamp flame. But the most remarkable indication given by the gasophaner is when it is held over a solution of sulphuretted hydrogen. The gasophaner immediately becomes pitted, as it were, with small-pox, on the surface next the gas; and these spots, on being examined with a microscope, are found to be round radiated crystals, the centre or nucleus of which soon bursts into a hole. They are white by transmitted and dark brown by reflected light. Nitride of boron gave exactly similar crystals as the chloride, and so did pure boracic acid. These crystals, therefore, are presumed to indicate a combination of boron with hydrogen—a fact hitherto unknown to chemists. The gasophaner can be reheated and reblown as often as required.

STEAM CULTIVATING MACHINERY.

SOME improvements in the construction of steam cultivating machinery have recently been patented by Messrs. Fowler and Co., of the Steam Plough Works, Leeds. In order to lift the tines out of the ground, to enable the implement to turn, and also in order to turn the implement, they mount upon it on an axis a lever to which, at its free end, the hauling ropes for drawing the implements to and fro are attached. When the implement has arrived at the end of its course, and what was the slack rope becomes the draft rope, the first action is to cause the lever to move round, and a pulley upon its axis then winds up a chain passing to a quadrant on the axle of the carrying wheels of the implement. The axle is thus turned partly round, and, being cranked at the ends where the wheels are carried by it, they are thus depressed in respect to the frame of the implement, or, in other words, the frame with the tines is raised. By the same motion of the lever, the acting rope is thrown to one side of the implement, and, consequently, the continued draft upon it causes the implement to turn round. When the turn is complete, the lever will have regained its original position, and the tines will be able to again enter the land. In order to prevent the tines commencing to penetrate the land before the turn is complete, a toothed arc is mounted on the cranked axle of the implement, and a catch takes into it when the tines are raised so as to prevent them descending until the catch is lifted by a hand lever.

Figs. 1 and 2 of our engraving show a side view and plan of a steam cultivating machine constructed on Messrs. Fowlers' improved plan. *a* is the main framing of the machine to which the tines are fixed; this frame has wings *b b* hinged to its sides, and these wings also have tines fixed to them, so that the implement may act upon a greater width of land; *c* is the main cranked axle carrying the road wheels *d*; *e* is the front castor and steering wheel; *f* is a chain wheel secured to a vertical spindle f^1 upon which is the draft and turning lever f^2, to the end of which are attached the hauling and slack ropes, Nos. 1 and 2; *g* is a quadrant fixed to the axle *c*. This quadrant is by a chain and screw coupling g^1 connected to the ends of a chain g^2 which passes around the chain wheel *f*, so that, if the draft lever be turned to one side or the other of the machine, the chain g^2 will be drawn forward, as shown by the arrow; *h* is a toothed arc fixed to the axle *c*; *j* is a catch lever carrying a tooth which enters into one or other of the teeth of the toothed rack *h*; *k* is a guard through which the rack *h* moves. In this guard are a number of holes through one of which a pin is passed to limit the extent to which the axle *c* can turn, and so regulate the depth of work; *l* is a steerage wheel, around the axis of which are wound two chains, one in one direction and the other in the opposite direction. These chains at their opposite ends are fixed to the two ends of a steerage lever *m* attached to the vertical axis of the castor *e*. The steerage wheel is worked by the man seated at the back of the machine on the seat *n*. The ends of the steerage lever carry eye bolts, so that a pair of horse shafts may be affixed when necessary.

A locking bar *o* is provided for locking the inside wheel when turning at the end of a bout; this bar can be moved endwise either to one side or other of the machine by a crank shaft *p* on which is a handle within reach of the man on the seat. The bar can thus be passed between the spokes of either one or other of the side wheels and so prevent its turning. When the machine is at work and has arrived at the end of a bout, as soon as the rope which before was the slack rope is hauled on, the draft lever f^2 turns to one side of the machine, carrying with it the draft rope. The tines are at the same time lifted out of the ground by the turning of the crank axle *c* which carries the side wheels, and the machine is free to turn. The tines are held up at this time by the catch *j*, so that they shall not again enter the ground until this catch is released by the attendant. During the turning of the implement, the attendant also locks the inside wheel by means of the bar *o*. When the implement has completed its turn, the draft lever f^2 will have regained its original position, and the tines will again enter the land so soon as the catch *j* is raised.

Fig. 3 shows a transverse section of an improved winding drum. *a* and *b* are the two parts or sections of the drum, each carrying a side flange. The part *a* has an external screw thread cut upon

it, whilst the part *b* is formed with a corresponding internal screw thread; *c c* are countersunk bolts passed through holes in the part *b* to enter slots in lugs cast on the part *a*, and the bolts are secured by nuts screwing on to them. If the bolts *c* are removed, the part *b* is free to turn around the part *a*, and the flanges on the two parts of the drum can thus be brought nearer to or further from one another, and then be again fixed by the bolts *c*. Fig. 4 shows a section of a winding drum in which the movable flange is secured to the drum by bolts and nuts. If the bolts are slackened, the movable flange can be set near to or further from the fixed flange, as desired.

AERONAUTICAL SOCIETY OF GREAT BRITAIN.

(Concluded from page 97.)

As to the speed which might be attained by aerial machines, nothing but practical experience can ever decide that point. Five hundred and two hundred miles an hour has been talked of; that, as the Americans would say, is "tall talk:" it can never be realized. When the wind sweeps along at the rate of one hundred miles an hour, we have, not a hurricane simply, but a terrific hurricane, blowing the masts from vessels, the roofs from houses, and the houses down themselves. When it decreases to eighty miles an hour the hurricane still blows, and even when it falls to sixty the storm continues. Now, it matters not whether it is the body of air sweeping past a fixed object, or the object sweeping through a quiescent body of air: the results are the same. If the rate of speed of either or both be one hundred miles an hour, a hurricane is the consequence. If this results in effects so destructive to a strongly-built vessel, what would they be on an aerial machine, which, from the very nature of the case, must be made light, and so comparatively speaking weak. That sixty and even eighty miles an hour might ultimately be found attainable is not at all improbable, when once the lessons of practical experience are capable of being brought to bear upon it, as there must be a great difference between moving in the midst of a conflict of elements, as is invariably the case on the surface of the earth or ocean, and moving rapidly along in a uniform quiescent mass of moving air (if I may be permitted so to speak), as is the case with the upper strata of our atmosphere. However, till such practical experience has been attained, we may be quite content with fifty; and this, when we do master the difficulty, as master it man will, the physical conditions of the case justly entitle us to hope to attain, and to attain it with ease, comfort, and perfect safety.

It can hardly be said that these views are at all extravagant or far-fetched, as the main principle upon which they are based is one with which we are already familiar, one which we see in successful operation amongst ourselves every day. The turbine wheel is an exhibition of it. Small working models of boats may be seen in shop windows running round and round for hours, driven only by two small jets of water on each side. Even steamboats of considerable size have been constructed and successfully worked on this principle, using water as the agent. These had to force their way not through a comparatively non-resisting fluid like air, but through sea water; and though they have failed to compete successfully with the paddle and screw, it was not because they did not work but because they did not pay. As for the weight that it would be requisite to take up, that dwindles to nothing when we learn that balloons have already been constructed capable of taking up to the extent of 16 and 22½ tons, the former referring to the captive balloon now in London, and the latter to an American balloon—a Mr. Lowe's.

The benefits to be derived from aerial navigation are not to be looked for so much from excessive speed, though their average may be expected to exceed the average of locomotives, as from the fact, first, that beyond the original cost, upkeep, and working of the machine, there will be little or no further expense; and, second, they will at once proceed from point to point: they will require to make no deviations, nor long rounds of any kind, to cross this valley or stream, or to clear that rugged cape or headland, as have the locomotive and the steamer. Then the danger will always be less. The risk of collision, *nil*; to compare them with railway carriages in that respect would be absurd. On the wide or open ocean the risk of collision in regard to vessels is small, and yet vessels afloat are all sailing on the same plane, and this a limited one—limited by the millions of square miles of land that rise above the ocean's surface. The plane, on the contrary, on which an aerial machine would move would be limited or curtailed in no such way, and even then it would very likely be the only object on that particular plane, vast as it might be, as, in all likelihood, every individual aerial machine would move in a plane peculiar to itself. There would be no fear of running off the rail, of landslips, or of miscreants putting stones or other obstacles on the line. There would be no fear of an angry sea, or of any of the dangers of the deep. A storm of wind might, however, sweep past on each side, but it would be a storm of their own creating, and one which would be completely under their own control.

Before closing, we might consider again for a few minutes the proposal to work aerial machines by means of the screw or wing principle, as there are phases in the working of the same which deserve very careful attention. The steam engine in its simplest form should give out all the power generated, and as long as that exceeds the resistance the engine should work very well. For instance, if the force generated is 5lb. to the square inch, and if the aperture of exit represents a surface of 20 inches, then the power exerted would be 100lb., and as long as the resistance continues less than that, the engine will overcome it. If, however, the resistance should increase, say, to 102lb., the engine will stop, the steam will escape as fast as it rises, and the power thus generated will be entirely wasted; and all this from an inability to increase the force by only 3lb. You have just to lessen or shut off by a valve the escape of steam for a short time, when the force within will increase; and, when it rises to 103lb., the engine will again work. Now, the introduction of piston, cylinder, and all the connecting rods, &c., belonging thereto, could have done no more; but they would add very much to the weight, and so tend to retard instead of adding to the end in view. Now, in aerial navigation, anything like an increase of weight is to be deprecated—it requires an equivalent in floating power; this adds to the bulk of the machine, and so increases greatly the difficulties to be overcome. All this takes place when you attempt to work an aerial machine, either by the screw or wing principle, driven by the ordinary steam engine.

The locomotive work of steam which it is called upon to overcome on land or sea, may be subdivided into three classes:—1st. Resistance arising from the air (when forcing the object moved through that element. 2nd. Resistance arising from the friction of all the various parts of the machinery by means of which it is required to exert its power. 3rd. Resistance arising from gravity which causes the object moved to cling to the nearest surface with a force more or less powerful.

The power required to overcome the first of the three foregoing is comparatively small; consequently, nearly the whole of the force exerted is so in overcoming the two last. Now, an aerial machine, constructed on the principle referred to in this paper, has nothing to do with the resistance referred to in the 2nd and 3rd of the classes mentioned above, but only with the first; and, as the power required is comparatively but small; the simple form of steam engine proposed may be found quite sufficient to such an amount of forward motion as will enable the machine to be brought under perfect command. If such is accomplished, we may be well content in the meantime, as further improvements would be sure to follow rapidly.

Again, in regard to the screw and wing principle, does it not appear that the former is the better method of the two? Any kind of motion which may be adopted as an equivalent for wings must be a reciprocating one. That must always prove a jerking one more or less. This necessitates strength; this, again, weight; and weight is destructive to the object in view. The screw principle, however, is an equal motion, the blades or fans balancing each other. Again, is an error not committed in throwing away the balloon as a sustaining power, and relying almost, if not entirely, on that derived from great speed in passing through the air. If anything should go wrong with the machinery, the destruction of the machine and all connected with it would be certain! Another objection to such is that they cannot rise without first skimming the surface of the ground for some considerable distance, where the chances are as ten to one that the wind would dash them to pieces against some of the many objects around ere they would be able to rise clear. Suppose, in regard to ocean sailing, that some one should bring out a new idea for a vessel, one of the principal points being that it would require to skirt the shore for a good many miles before it dare strike out for mid ocean, would you not say that the improvement was a very doubtful one indeed? Just so with the balloon *versus* the wing sustaining principle. The floating power of the balloon permits it to rise at once into mid-air, clear of all the dangers of the surface; and yet it is proposed to throw this aside for a machine which cannot rise before it has exposed itself and all within it to almost certain destruction. No more need be said on that point.

It may just be remarked that the great hindrance to aerial navigation is the want of a motive power equal to steam, but generated from only a few pounds' weight. Give us that, and the difficulty will be solved at once; without it, you cannot even test the suitability of any appliance that may be laid before you. The plan suggested in this paper is but a rude attempt to turn steam as we have it to account; but it remains to be seen if even it will succeed. Gunpowder appears, at first sight, as if it were something like the thing required; but when you come to examine it, though only in the mind, you soon perceive how it can never be made to act. Its two faults are, first, that its explosive properties must be given to it before forcing it into the power generator; and, second, its condition as a powder, or, in fact, any other form. Another powerful agent, even greater than powder, has lately come into notice—nitro-glycerine; and, as its constituents are liquids, these might be forced, in the proper proportions, into the power generator (the equivalent for the steam boiler), and, exploded within that. Could this be accomplished, a motor such as is required would be attained.

Mr. Moy believed he was the first to mention 150 miles an hour, and he ought therefore to defend his statement. He explained that, by the construction of the lines, an extremely small resistance would be offered to the wind.

Mr. Wenham, with regard to what had been said on air cells in birds, said that some of the fastest flyers are completely destitute of them, while the pelican, penguin, and emu are completely enveloped with them. It was, therefore, clear that the air cells had nothing to do with flying.

After some remarks by Mr. Quartermain, suggesting the employment of more powerful agencies than steam, provided that the residuum which corrodes could be got rid of, Mr. Brearey stated that twenty years ago Mr. Stringfellow made a model which flew like a pheasant and carried its own steam engine and boiler.

Mr. Wenham suggested that experiments on the force of wind should be made by the use of a dynamometer.

The Chairman said that one of the suggestions made was tried more than twenty years ago by means of a spring. A model with 5 square feet of surface and a pair of wheels that moved in opposite directions flew 10 or 12 yards.

Major Phillips asked what sort of sustaining power was used.

The Chairman said there were two planes inclining towards each other at an angle, and driven by two screws which moved in opposite directions.

Major Phillips: And by what means was it sustained?

The Chairman: The resistance obtained by the rotation of the screws.

Mr. Olrick remarked that if any man had designed a ship to move in the manner of a fish by its fins and tail, it would have been an utter failure. On the same ground, he submitted that something different from the wing of a bird should be thought of for the purposes of flight. In the use of models inventors were working against themselves, because they got too much weight. A machine of a reasonable size and of a few horse power could be made quite as cheaply as a model. The model maker, as a rule, did not understand how to make a machine, and could not make it cheaply.

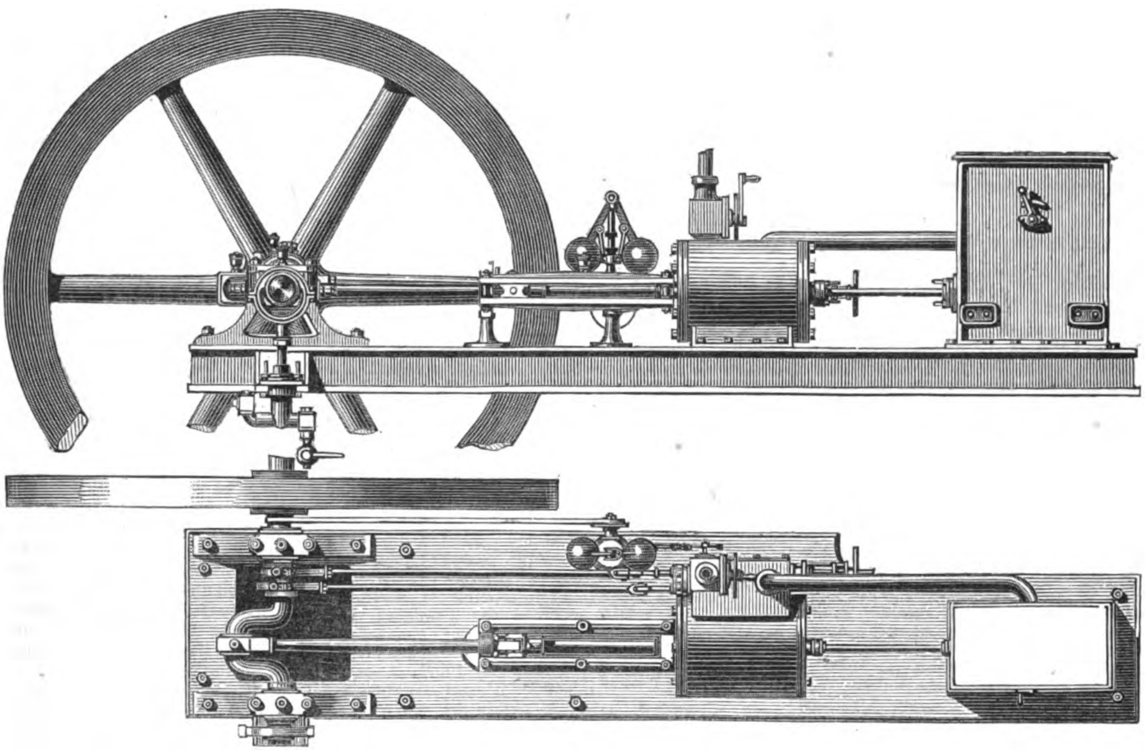
Before the meeting broke up, thanks were accorded to the authors of the papers, to the Society of Arts for the use of the room, and to Mr. Brooke for presiding.

THE LONDON AND COUNTY BANK.

THE half-yearly meeting of the proprietors of the London and County Banking Company was held on the 5th instant at the City Terminus Hotel, Cannon-street, Mr. Frederick Francis in the chair. From the report of the directors we are glad to find that, after paying interest to customers, and all charges, allowing for rebate, and making provision for bad and doubtful debts, the net profits amounts to £85,010 2s. 7d. This sum, added to

TWELVE-HORSE POWER STATIONARY ENGINE.

BY THE READING IRON WORKS COMPANY.



£5,817 4s. 10d. from last account, produces a total of £90,827 7s. 5d. The usual dividend of 6 per cent., with a bonus of 2½ per cent., for the half year, free of income tax (being at the rate of 17 per cent. per annum), will absorb £84,601 9s. 10d., and leave £6,225 17s. 7d. balance. In commenting upon the balance-sheet, which was very satisfactory, the chairman observed that the balances of the bank had increased £400,000 since this time last year. Acceptances were £200,000 less than last year. Interest paid to depositors was £20,000 more than last year. The rate of interest during the past six months was somewhat more than the whole of the preceding year, while the profit made by the bank was greater. In proportion to other banks, there was much cause for satisfaction with the progress of this bank. Another gratifying feature, as showing the prosperity of the bank, was that 2,500 new accounts had been opened at the head and branch offices since last year; and with 160 shareholders since the same period, there were now 2,900 partners in the concern. The chairman moved the adoption of the report; Mr. Champion Jones seconded the motion, which, we need hardly say, was carried unanimously. The proprietors have cause to congratulate themselves on their present satisfactory position.

THE METRIC SYSTEM.

THE second report of the Commissioners appointed to inquire into the condition of the Exchequer (now Board of Trade) standards, that bearing on the question of the introduction of the metric system of weights and measures into the United Kingdom, has been published. The Commissioners have unanimously agreed upon the following resolutions :—

1. Considering the information which has been laid before the commission, of the great increase during late years of international communication, especially in relation to trade and commerce, of the general adoption of the metric system of weights and measures in many countries, both in Europe and other parts of the world, and more recently in the North German Confederation and in the United States of America, of the progress of public opinion in this country in favour of the metric system as a uniform international system of weights and measures, and of the increasing use of the metric system in scientific researches and in the practice of accurate chemistry and engineering construction, we are of opinion that the time has now arrived when the law should provide, and facilities be afforded by the Government, for the introduction and use of metric weights and measures in the United Kingdom. That for this object metric standards, accurately verified in relation to the primary metric standards at Paris, and deposited in the Standards Department of the Board of Trade, should be legalized, and hat verified copies of the official metric standards should be provided by the local authorities for inspectors of such districts as may require them.

2. Considering the advantages of adopting in an international system not only of uniform weights and measures, but also uniform names; and that although there may be well founded objections to the inconvenient length and occasional similarity, both to the eye and ear of the French nomenclature, yet it is probable that these names will become familiar by custom, and obtain popular abbreviations. We think that the French nomenclature, as well as a decimal scale of the metric system, should be introduced in this country.

3. Considering that there is no immediate cause requiring a general change in the existing system of legal weights and measures of the country for the purposes of internal trade; that the statuteable values of the fundamental imperial units are adopted in use without the slightest variation throughout the whole of the British Isles; that the primary imperial standards are as perfect as can be made by modern skill and science, and that the whole series of official standards are now most accurately verified in relation to the primary standards; that a very large number of copies of the official imperial standards, accurately verified, are now in use by the local inspectors of weights and measures; that it is estimated there are nearly 30 millions of ordinary weights and measures of the existing imperial system now in common use; that at the present time there is no evidence to show that any considerable portion of traders and their customers in this country are dissatisfied with the imperial system now in use, or that they desire to substitute the metric system for it; we are of opinion that the general introduction of the metric system should be permissive only, and not made compulsory by law after any period to be now specified, so far as relates to the use of metric weights and measures for weighing and measuring goods for sale or conveyance.

4. Considering that during the concurrent use of the metric and imperial systems, it will be expedient to prevent as far as possible imperial and metric weights and measures from being accidentally or fraudulently substituted for each other. We are of opinion that authoritative regulations should be established, under which each series may be readily and easily distinguished, by the adoption of conspicuous distinctive forms or marks for the several weights and measures, and by such other mode as may be determined upon after due inquiry.

5. We are of opinion that it is expedient customs duties should be allowed to be levied by metric weight and measure, as well as by imperial weight and measure; that the use of the metric system, concurrently with the imperial system, should be adopted by other public departments, especially the Post Office, and in the publication of the principal results of the statistics of the Board of Trade, as well as for the admeasurement and registration of the tonnage in shipping.

6. And that mural standards of the metric system, as well as of the imperial system, be exhibited in public places.

7. Considering that the metric system, as adopted in other countries, includes the relation of coinage to weights and measures, particularly in its uniform decimal scale. And that the advantages of the introduction of the metric system into this country, as an international system of weights and measures, would be much increased by establishing a corresponding international system of coinage, in regard to a unit and to a decimal scale. We are opinion that, even if the difficulties of establishing an international unit of coinage cannot be at present overcome, yet the decimalization of our system of coinage, which is in the power of the Government, would be very useful to the public.

8. Considering the great national importance of the question of the introduction of the metric system of weights and measures into this country, it appears to us essential that any measure for this object should be proposed to Parliament by the executive government.

9. Considering that the commission will very shortly enter upon the questions referred to them relating to the system of local inspection of weights and measures throughout the United Kingdom, we are of opinion that it is expedient that no legislation should take place with respect to the metric system until the whole subject of the weights and measures of this kingdom be brought before Parliament in one bill.

The Commissioners signing the report are:— G. B. Airy, Chairman; Colchester, Stephen Cave, John George Shaw Lefevre, Edward Sabine, Thomas Graham, W. H. Miller, H. W. Chisholm.

THE READING IRON WORKS STATIONARY ENGINE.

IN the accompanying engraving we illustrate an excellent type of stationary engine which we met with at the stand of the Reading Iron Works Company at the late Manchester Show. The engine is of 12-horse power, and is one of a class specially designed to insure economy in the consumption of fuel. The cylinder is made in one casting with the valve chest, and steam jacketed throughout. The engine is fitted with variable expansion valves, so arranged as to be capable of the most minute adjustment while working at full speed. All the wearing surfaces are got up with the greatest care, so as to produce the least possible friction while running. When supplied with steam from a suitable boiler, the manufacturers can guarantee a consumption of fuel of about 2¼lb. per horse-power per hour in engines of 12-horse to 20-horse power, and in higher power a more economical consumption. The Reading Iron Works construct their engines from 4-horse to 40-horse power, the one illustrated being their nominal 12-horse.

The cylinder, condenser, crank shaft, bearings, and all different parts, are erected on a cast-iron

bedplate, which alone is secured to the masonry foundations. The air pump is double-acting, the air pump valves being of india-rubber. The force pump is supplied with water from the condenser. The governors are adjusted to allow the engine to work at a speed of 90 revolutions per minute. The following are some of the principal dimensions:—Diameter of cylinder, 12½in.; length of stroke, 16in.; diameter of air pump, 4in.; stroke of air pump, 16in.; diameter of force pump, 2¼in.; stroke of force pump, 2¼in. The space occupied by the engine in plan is 12ft. 11in. by 2ft. 9in.

ANNUAL INTERNATIONAL EXHIBITIONS OF SELECTED WORKS.

HER MAJESTY'S Commissioners for the Exhibition of 1851 announce that the first of a series of annual international exhibitions of selected works of fine and industrial art will be opened in London, at South Kensington, on Monday, May 1, 1871, and be closed on Saturday, September 30, 1871. The exhibitions will take place in permanent buildings, about to be erected adjoining the arcades of the Royal Horticultural Gardens. The productions of all nations will be admitted, subject to obtaining the certificate of competent judges that they are of sufficient excellence to be worthy of exhibition. The objects in the first exhibition will consist of the following classes, for each of which will be appointed a reporter and a separate committee:—

I. Fine Arts.—1. Painting of all kinds, in oil, water colours, enamel, porcelain, &c. 2. Sculpture in marble, wood, stone, terra cotta, metal, ivory, and other materials. 3. Engravings, lithography, photography, &c. 4. Architectural designs and models. 5. Tapestries, embroideries, lace, &c., shown for their fine art and not as manufactures. 6. Designs for all kinds of decorative manufactures. 7. Copies of ancient pictures, enamels, reproductions in plaster, electrotypes of fine ancient works of art, &c.

II. Scientific Inventions and New Discoveries of all Kinds.

III. Manufactures.—(a.) Pottery of all kinds, including that used in building, viz., earthenware, stoneware, porcelain, parian, &c., with machinery and processes for the preparation of such manufactures. (b.) Wool and worsted fabrics, with the raw produce and machinery for manufactures in the same. (c.) Educational—1. School buildings, fittings, furniture, &c; 2. Books, maps, globes, &c.; 3. Appliances for physical training, including toys and games; 4. Specimens and illustrations of modes of teaching fine art, natural history, and physical science.

IV. Horticulture.—International exhibitions of new and rare plants, and of fruits, vegetables, flowers and plants, showing specialties of cultivation, will be held by the Royal Horticultural Society, in conjunction with the above exhibitions.

In Classes II. and III. producers will be permitted to send one specimen of every kind of object they manufacture, such object being distinguished for novelty or excellence. Detailed rules, applicable for each of the above classes, and lists of the separate trades engaged in the production of objects of manufacture, will be issued. Special rules for horticultural exhibitions will be issued by the Royal Horticultural Society. The arrangement of the objects will be according to classes and not nationalities, as in former international exhibitions. One-third portion of the whole available space will be assigned absolutely to foreign exhibitors, who must obtain certificates for the admission of their objects from their respective governments. Foreign countries will appoint their own judges. The remaining two-thirds of the space will be filled by objects produced either in the United Kingdom, or, if produced abroad, sent direct to the building for inspection and approval of judges selected for the British exhibitors. Objects not accepted for exhibition must be removed according to the notices given, but no objects exhibited can be removed until the close of the exhibition. All exhibitors, or their agents, must deliver at the building, into the charge of the proper officers, the objects unpacked and ready for immediate exhibition, and free of all charges for carriage, &c.

Her Majesty's Commissioners will find large glass cases, stands, and fittings, free of cost to the exhibitors, and, except in the case of machinery, carry out the arrangement of the objects by their own officers. Her Majesty's Commissioners will take the greatest possible care of all objects, but they will not hold themselves responsible for loss or damage of any kind. Prices may be attached to the objects, and exhibitors will be encouraged to state their prices. Agents will be appointed to attend to the interests of exhibitors. Every object must be accompanied with a descriptive label, stating the special reason, whether of excellence, novelty, or cheapness, &c., why it is offered for exhibition. Due notice will be given of the days for receiving each class of objects; and, to enable the arrangements to be carried into effect, strict punctuality will be required from all exhibitors, both foreign and British. Objects delivered after the days appointed for their reception cannot be received.

Reports of each class of objects will be prepared immediately after the opening, and will be published before June 1, 1871. Each foreign country will be free to accredit an official reporter for every class in which objects made in such country are exhibited, for the purpose of joining in the reports. There will be no prizes, but a certificate of having obtained the distinction of admission to the exhibition will be given to each exhibitor. A catalogue will be published in the English language, but every foreign country will be free to publish a catalogue in its own language if it think fit.

THE NEW PATENT LAW FOR CANADA.

CANADA has found a short and ready means of dealing with the question of patents. While we are discussing the whole principle of the Patent Law, the Parliament of the Dominion has not only settled the principle of such a law, but has fixed the practice. We regret to state, however, that both principle and practice may be concisely summed up in the word "spoliation." Our great transatlantic dependency has shown its independence by abolishing patents so far as outsiders, whether British or foreign, are concerned, and limiting the protection of inventors to residents in the Dominion. Under this law no foreigner, not even an English fellow-subject, can hold any patent in Canada; nor can any Canadian hold one in his behalf. The patent can only be granted when the discoverer or inventor has lived in Canada for the twelve months preceding the application or, in case of his decease, for the twelve months immediately preceding that decease. By this Act, which received the assent of the Governor-General on June 22, Canada at once helps herself to all foreign discoveries. Canadian inventors, if there are any, are protected both at home and abroad, but English and American inventors are denied all reciprocal benefit within the area of the Dominion. We are not concerned for American patent-holders; the policy of confiscation has been taught the Canadians by the copyright law of the States; but we have a right to protest against the injustice which Canadian exclusiveness inflicts on patentees in the mother country. Our colonies want to have all the benefit of their connection with us, and not only to inflict upon us all the expense, but every conceivable disadvantage. We pay large sums to protect them against invasion or affront, and they show their gratitude not only by "protecting" themselves against our manufactures, but in this Canadian case by robbing our inventors. Has the Colonial Office nothing to say to this policy? It is perhaps too much to ask, as Mr. Bentall did last night, that the Queen should be advised to refuse her assent to the bill; but it would be no interference with Canadian independence to point out its impolicy and injustice. We are glad that since the Under-Secretary answered Mr. Howard's question on Tuesday the office has heard of the bill, though only through Mr. Howard and the newspapers. But might it not at least know what the colonies are doing, and keep them in mind of their duties to the mother-land, which fosters and protects them? The Colonial Office is, at least, a home institution; and it is as much its duty to remonstrate with our undutiful children against their ill-treatment of their mother, as it is to look after the interests of young sprigs of nations which are so well able to look after themselves.—"Daily News."

ECONOMIC PUMPING ARRANGEMENTS.

DURING the last twelve months a system of pumping has been in use at the Botany Bay pit, belonging to the Clifton and Kersley Coal Company, Manchester, which is worthy of notice from the peculiar circumstances it was designed to meet, and the success which has attended it. According to the "Mining Journal," in the down brow, about 150yds. from the shaft, a feeder of water was unexpectedly cut, which yielded nearly 750 gallons of water per minute, and caused considerable inconvenience in the pit. The down brow having an inclination of 10in. in the yard, the point of irruption was about 125ft. below the sump. All the workings speedily become entirely flooded, upwards of 20 miles of workings being under water, and for more than a week there was a regular flow into the sump itself. By keeping the ordinary lifts at full work, and by continuous winding, the water was just kept to the sump level for seven months, when temporary direct double-acting steam pumps were put in to relieve the winding—the water was pumped from the down brow into the sump by a Gwynne's centrifugal pump, running 200 revolutions per minute, and the direct-acting pumps made about 60 revolutions per minute. The entire system was kept at work night and day for two years, and raised by measurement 493 gallons per minute. Upon the pit coming into the possession of Mr. Josiah Evans, of Haydock, it was determined to substitute for the four 6-inch pumps two horizontal 13-inch pumps, with 34-inch steam cylinders, 2ft. stroke, and to substitute for the centrifugal pump an improved system of plunger. The quality of the work usually turned out by Messrs. Routledge and Ommaney is already so well known in the Manchester district that more need not be said in favour of the machinery at Clifton than that it is constructed in their usual style, and works admirably. A pair of 20-inch cylinder engines, 4ft. stroke, is placed on the incline of the down brow at the bottom of the shaft, and these are used to work a pair of Messrs. Routledge and Ommaney's 17-inch plunger pumps off continuations of the engine piston rods. The pumps are placed on a heavy cast-iron truck, running on a suitable tramway. As the water is pumped out, the pump rods are from time to time lengthened and supported on sheaves resting on the delivery pipe. The inclined pumps raise the water a height of 125ft. through a column of pipes nearly thrice that length. The advantage which this arrangement secures is that the work is done with the minimum expenditure of force, and that the previously existing arrangements of the pit are not in any way interfered with.

Correspondence.

THE NEW CANADIAN PATENT LAW.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In your leader of last week on the New Patent Law of Canada, you refer to a question asked in the House of Commons by Mr. James Howard, on the previous Tuesday evening. This question was repeated on the Thursday evening by Mr. Bentall, and unfortunately elicited a still more unsatisfactory reply from Mr. Monsell; at least, as far as can be gleaned from the reports in seven of the morning newspapers, every one of which differs in the account of what he said.

The substance of Mr. Monsell's reply appears to have been as follows:—"That no copy of the new Act had yet reached the Colonial Office; that all the knowledge of it he possessed was derived from a copy given in a Canadian newspaper; that the Act appeared to be an assimilation of the different laws on the subject of patents that had formerly existed in the colonies of Canada, Nova Scotia, and New Brunswick; that the Home Government had no intention to advise her Majesty to withhold her assent to the Act; in fact, such a refusal was impossible, as the power of the Crown so to do had been taken away by a *recent* Act of Parliament, to wit, the Imperial Act, 15 and 16 Vic., cap. 83, sec. 18."

If this last assertion had been true, the suggestions made in your leader of last week, and in my letter also, would be of no avail; but I am informed that such is not the case. The general power of the Crown to deal with and review the Acts passed in our various colonies is a question of public policy and of large application, and is in nowise affected by the clause in the Act cited by Mr. Monsell, which is, in fact, our present Patent Act of 1852. This authority of the Crown was exercised lately in the case of a money grant to Governor Darling in Australia, and also in the matter of the Indian Patent Law. The Indian Patent Law was enacted and put in force in India for some months, when the Home Government, for certain reasons, interfered and cancelled what had been done.

I trust that others abler than myself to deal with this question will take the matter up, as it affects not only inventors but patent agents also.—I am, Sir, yours, &c., JOHN FORDRED.

Blackheath, S.E., Aug. 10.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribe of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Naval, Military, and Gunnery Items.

An account has just been issued, showing the receipt and expenditure or naval prize, bounty, salvage, and other moneys between April 1, 1868, and March 31, 1869. The total amount awarded was £81,866 9s.

It is stated to be the intention of the Lords of the Admiralty to inaugurate the basin and dock at Haulbowline, at the end of September next. The mayor and corporation of Cork are to be invited to meet their lordships.

At the last meeting of the Mersey Docks and Harbour Board, it was reported that the earnings of the Mersey pilot boats during the year ending the 30th of June last were £65,058, showing a decrease of £3,531, compared with the previous year.

A new fog trumpet has lately been erected on Thacker's Island, off Gloucester, Massachusetts, which is operated by an Ericsson caloric engine, rotates through an arc of 180deg., and gives a blast of seven seconds' duration, at intervals of forty-three seconds.

The result of the firing of the "Hercules" guns with 60lb. charges, and projectiles varying from 380lb. to 400lb., at the highest and lowest elevations, has been a complete success. The working of the carriages is stated in private letters to have all the ease with which the lightest naval guns have been hitherto worked.

The yellow fever has made sad havoc on board the "Eclipse." Her captain, first lieutenant, and sixteen of her crew have fallen victims to the scourge. Captain Harvey (one of the Walmer Harveys) has left a widow and family in this country to regret the loss they have sustained.

The "Sirius" was put through the official trial of speed on Friday last, over the measured mile in Stokes Bay, near Portsmouth, and under full boiler power realized a mean speed of 13·1 knots per hour. With half-boiler power she attained a mean rate of 11·3 knots. She will sail immediately from Spithead for her term of service on a foreign station.

Lieutenant-Commander H. B. Seely, of the United States steamer "Fawnee," has been arrested at Portsmouth, New Hampshire, on two warrants, charging him with unwarranted cruelty to several of the seamen of that vessel, by tying them up by the wrists, and thus inflicting punishment on them so severe that one of them fainted from exhaustion, and another lost the use of both hands.

The "Cerberus" turret ship was recently taken down the Channel, outside the Nore, for the purpose of testing the working of her balance rudder since the alterations made in the steering arrangements of the vessel. During the trial the vessel was found to steer in a far from satisfactory manner, and she will be again docked for the purpose of having some further improvements effected in her rudder.

Although predictions of disaster as to her voyage out were plentiful, the great Bermuda dock has arrived safely at the island. The passage was made, it would appear, under favourable circumstances. The absence of suitable dock accommodation at Bermuda has long been felt, and now that this want has been so well supplied, war ships on the North American and West Indian stations can be overhauled and repaired, instead of being sent home for those purposes.

Yesterday week, Messrs. Laird Brothers launched from their yard at Birkenhead a small screw steam yacht, which they have built for Earl Grosvenor, for use on the lochs adjoining his estate on the coast of Sutherlandshire. She was christened the "More Vane," by Miss Annie Laird, daughter of Mr. John Laird, jun. The accommodation for passengers is in a raised house forward, with large ports, the crew being provided for in a small house at the after end of the engine space. The engines being on board the "More Vane" at the time she was launched, the yacht was at once tried, the machinery working most satisfactorily.

Nearly the whole of the coal required for the use of the dockyard and for consumption on board the ships of war in port at Pembroke is now brought by rail direct from the collieries in the Aberdare and Monmouthshire Valleys. Formerly, the coal had to be shipped at Cardiff and Newport, or if sent by the Great Western Railway it had to be transhipped at New Milford at considerable expense. The new arrangement will effect an important saving in the cost of the coal, and if the contemplated branch line from Pembroke and Tenby into the dockyard is made, a further reduction in the cost of fuel and in the carriage of all other articles required for the dockyard will be the result.

From the Clyde we learn that Messrs. Caird and Co., of Greenock, have launched a steamer, named the "Hanover," for the North German Lloyd. The "Hanover" is intended for the Bremen and New Orleans trade. The "Palmyra," screw, built for Messrs. Salledo and Co., a Spanish firm, by Messrs. W. King and Co., has made a favourable trial trip. The "Palmyra" is of the following dimensions:—Length, 96ft.; breadth, 19ft.; depth of hold, 9ft.; burden, 200 tons, builders' measurement. She is fitted with inverted cylinder condensing engines of 30-horse power.

H.M. turret-ship "Monarch" proceeded from Spithead to Portland on Thursday morning week, and tested her 25-ton guns and carriages *en rout*. A large number of battery charges were fired with complete success, the guns and carriages answering admirably under the severe test of continuous discharges of a 600lb. projectile with 70lb. of powder. The carriages, which are compound pivotting, are four in number (two in each turret), were made at Chatham Dockyard, under Mr. Eames's immediate superintendence, from designs furnished by Captain Scott, R.N., and the guns, which weigh 25 tons each, are of the land service pattern.

We ("Cork Herald") understand that it is the intention of the official authorities to have H.M.S. "Scorpion," now lying in this port, immediately dismantled. It appears that on a recent trip to sea she proved herself a most dangerous craft, in consequence of her extraordinary low freeboard. Many times she was almost submerged in the sea, and she occasioned such panic to her crew that they have protested against proceeding again to sea in her. The "Scorpion" was originally built for the Confederate States, but in order to avert another "Alabama difficulty" she was purchased by the English Government out of the builder's hands, together with her consort, the "Wyvern," an equally disreputable sea-going vessel.

The introduction of Adams's breech-loading revolver into the service having been decided upon, the Deane and Adams' pistols already in use are now being converted by Mr. Adams. A number have been already finished. The converted pistol differs from the new in having five chambers instead of six. A central-fire cartridge has been designed for it by Colonel Boxer, R.A., superintendent of the Royal Laboratory Department, Royal Arsenal.

A rifle contest, of a kind of which there might well be more, was held the other day at the rifle range of the Eccleshill company (included in the Bradford corps) of Rifle Volunteers in Culverley Wood, near Bradford. The competitors were ten of the 40th Regiment, now quartered at the Bradford Barracks, and ten men of the Eccleshill company The Regulars used a Snider rifle and the Volunteers an Enfield. The Regulars made 332 points at 200. 300, and 400 yards, five shots at each, and the Volunteers 349. The honours of the contest, therefore, remained with the Volunteers, but there will be a return match.

Mr. E. J. Reed, C.B., the Chief Constructor of the Navy, is ill from the result of his close attention to his duties at Whitehall, and has gone to Paris, where he will remain for several weeks. Within the last few days the Lords of the Admiralty have forwarded two letters to Mr. Reed, in which their Lordships express their unqualified satisfaction with the results of the recent performances, under steam, of the ironclad turret-ship "Monarch," 7, 1,100-horse power, just completed at Chatham, and the "Inconstant," iron wood-cased frigate, built at Portsmouth. Their Lordships have likewise informed Mr. Reed that, in consequence of the great saving to the country which has resulted from the adoption of his system of constructing ironclads, and as a mark of the value they attach to his services, they have been pleased, with the full concurrence of the Chancellor of the Exchequer and the Treasury, to increase his salary by £500, making it £1,700 per annum, an event upon which we congratulate the Chief Constructor.

Miscellanea.

The quantity of amber lately found in the Kurischen Haff, to the north of Konigsberg, is said to be so great that the market price of the article has fallen.

A new auriferous strata has been discovered in that part of Siberia traversed by the affluents of the Angara, at a distance of about 250 miles from Teneissisk.

We understand that Lord Stanley has consented to distribute the prizes to the students of the Birkenhead Government School of Science and Art at a meeting to be held about the end of October.

The total number of passengers using the Metropolitan, the Metropolitan District, the St. John's Wood, and the Hammersmith and City lines, during the half-year ending June 30, 1869, was 20,087,809.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending August 7, was 4,311. Total number since the opening of the Museum, free daily (May 12, 1858), 1,616,665.

An enthusiastic party of antiquarians lately made a laborious excavation at Ossian's tomb, at Glen Almond (or what is supposed to be the grave of the ancient bard), and, according to the "London Scotsman," were successful in discovering some fragments of—a champagne bottle.

We are requested to state that the improvements in Golay's Millstone Dressing Machine, which was exhibited by Messrs. Bryan Corcoran and Co., and described in our last issue, were invented and patented by Mr. Corcoran, of that firm, and Mr. Dunham, of the firm of Clarke and Dunham.

A deputation, consisting of Mr. J. W. Probyn, Mr. Thomas Paterson, and others, had an interview with the Right Hon. J. Bright, at the office of the Board of Trade, yesterday week, to bring under his notice the defective state of the law regarding the protection of inventions at industrial exhibitions.

The number of visitors to the South Kensington Museum during the week ending August 7, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 12,900; Meyrick and other galleries, 2,714; on Wednesday, Thursday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,713; Meyrick and other galleries, 183; total, 17,510. Average of corresponding week in former years, 12,266. Total from opening of Museum, 8,675,801.

The Wire Tramway Company have contracts at present in execution in France for about 25 miles of wire tramway, all for beet sugar makers. Mr. Hodgson, the inventor, is at present engaged constructing the line for the Pestarena Company in the Alps; besides this, the company have contracts in Spain, Sweden, and Austria, and are shipping lines to New Zealand and Peru. Several short lines are in course of construction in England, and the difficulty of obtaining right of way is alone preventing them doing a large business in this country.

We ("Athenæum") regret to announce the death, at Lisbon, on the 8th ultimo, of a veteran both in literature and science, Dr. John Martin. So far back as 1817 he was the editor of "Mariner's Tonga Islands," a work which has been always held in high estimation. Dr. Martin laid down meteorological charts representing the varying aspect of months, seasons, and years from daily observation. He also made careful observation with reference to ozone, as well as on the characteristics and circumstances affecting cholera and yellow fever. Dr. Martin died at the advanced age of 80.

The competition for the practical work for the ten Whitworth scholarships of £100 each, will be conducted by Colonel Rich, R.E., Mr. Manby, secretary of the Institution of Civil Engineers, and Mr. Marshall, secretary of the Institution of Mechanical Engineers. In addition to these scholarships tenable for the present year, Mr. Whitworth has just offered to the Science and Art Department 80 exhibitions of the value of £25 each, to be awarded to students in the universities, colleges, and schools, public and private, in the United Kingdom. These exhibitions are to be held for one year, and the students must show an aptitude for mathematics, mechanical science, and drawing.

The beer bottles are getting worse and worse in India, and the sherry bottles are following their pernicious example. According to the "Madras Mail," the pint bottle, from England, capsuled and labelled *a la mode*, now contains but a few drops more than half an imperial pint. Possibly the brewers have satisfied themselves that copious draughts of iced beer are bad for the liver, and on purely benevolent grounds are diminishing the supply. If they would reduce the price in proportion as they reduce the capacity of their bottles, no one would object to the solicitude that they show for Anglo-Indian stomachs.

The following is a return of the quantity of coal exported from Grimsby,—July, 1869.—To Belgium, 610 tons; to Canada, 688 tons; to Denmark, 3,408 tons; to Egypt, 1,513 tons; to France, 3,359 tons; to Hanseatic Towns, 702 tons; to Holland, 605 tons; to Moldavia and Wallachia, 576 tons; to Norway, 1,044 tons; to Prussia, 3,010 tons; to Russia, 6,744 tons; to Sweden, 2,776 tons; to Spain, 476 tons; to Turkey, 145 tons—total to foreign ports, 25,824 tons; coastwise, 3,942 tons; total, 29,766 tons. Corresponding period, 1868,—to foreign ports, 29,660 tons; coastwise, 8,480 tons; total, 38,140 tons, showing a decrease of 8,374 tons.

Last week a party of town councillors and others in New Hall-street, Birmingham, were inspecting a steam roller, when an unlooked-for accident occurred. There is a considerable declivity, about 1 in 40, at the spot where the affair occurred, and when the ponderous machine, some 25 tons in weight, was going slowly down, doing its work well, a pin in the braking apparatus gave way, and the engine started off at a rapid pace down hill. The two men in charge did their best to bring it to a stop, but it got completely beyond control, and, running on to the pavement, dashed into the factory of Messrs. Elkington and Co. Two windows and part of a wall were smashed in, but fortunately no one was injured. The men jumped off before the collision occurred.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

82 C. W. SPONG, Clapton Park. *Railway carriages.* Dated January 11, 1869.

The inventor proposes to employ sliding doors instead of swing doors, to avoid the possibility of accidents arising either from the doors not being properly fastened or becoming accidentally opened whilst a train is in motion. The door may either be suspended from a fixed rod or run on rollers on a rail or bar at the bottom or top of the door, or both. The side of the carriage is suitably formed to receive the door when it is required to be drawn or pushed back to admit persons. He also proposes to pad the meeting edges of the door and door frame, to lessen injury in the event of persons' hands or fingers being in the way of the closing of the door. The door may be kept securely closed by a swivel hook, fixed between the linings of the carriage, taking hold of a pin or eye on the edge of the door, the hook to be disengaged by a handle fixed at the outside of the carriage. A disc or ball may also be connected with the lock of the door, to show when it is open. The inventor further proposes to make the window of the door to slide sideways instead of up and down, as is now the case; and, as regards hand rails, he proposes to fix a rod to the outside of the carriage the entire length or height of the door frame at one or both sides thereof, to afford greater facility to persons to catch hold of than the means at present employed; and, as regards the steps of railway carriages, which are now formed of long planks of wood, the width whereof is such as to leave considerable space between the edge of the step and the edges of the platforms at the several stations on a line of railway, and by which many serious accidents have happened to persons about to enter and alight from a train, the inventor proposes to obviate this by making the step sufficiently wide to project over the edges of the platforms, sufficient space being left between the surface of the platforms and the under side of the carriage steps for the weight springs of the carriages to act.—Patent abandoned.

83 J. H. JOHNSON, Lincoln's Inn. *Pulp boxes, &c.* (A communication). Dated January 11, 1869.

This consists, essentially, in forming boxes and similar articles by forcing a plunger down into a mould containing the pulp, after which an outer or annular plunger surrounding the former one is brought down between the external sides of the inner plunger and the internal sides of the mould, in order to form the end or top of the box, and to compress the sides longitudinally or in a downward direction. The first-mentioned plunger works in connection with an internal piston, which is provided with an air inlet valve, which allows air to enter beneath the lower end of the plunger just previous to its withdrawal from the cavity of the completed box, whereby such withdrawal is greatly facilitated, and no tearing of the box is produced. The first descent of the central plunger into the mould is effected by a sudden and quick motion, in order that the pulp may be displaced and run up the sides of the plunger, so as to form the sides of the box, and not to be consolidated at the bottom of the mould, which would be the case if the plunger descended slowly. This displacement of the pulp having been accomplished, the plunger may complete the rest of its descent by a slow motion. Two duplicate moulds are employed made in a sliding block which traverses to and fro along guideways underneath the plunger on the bed or table of the machine, so as to make one mould to be supplied with pulp whilst the box or hollow article is being made inside the other mould, and *vice versa* the completed article being expelled by the action of the annular cylindrical plunger which forces the box out through the bottom of the mould, when it drops into an endless travelling apron of cloth or wire gauze. To allow of this action, the moulds are each provided with removable bottoms. In order to admit of the drainage and free escape of the water from the pulp in the moulds, their sides and bottoms are channelled and covered with a permanent or fixed perforated or permeable lining, the bottoms being, moreover, perforated underneath such lining. This machine may be driven either by hand or by any convenient prime mover.—Patent completed.

84 F. C. MATTHEWS, York. *Treating Indian corn.* Dated January 11, 1869.

The Indian corn or maize is thoroughly saturated with water (which may be slightly acidulated), and, by preference, it is steeped in the water for a period of about seven days. It is then taken out and allowed to commence to grow. When the growth has progressed sufficiently, the Indian corn or maize is dried at a moderate heat sufficient to kill it and stop the growth, and it is then the new product, suitable for use in brewing and distilling, and as food for cattle.—Patent abandoned.

85 C. N. NEWSOME, Coventry. *Milk cans.* Dated January 11, 1869.

The inventor prevents the shaking of the milk by the construction of a can which is capable of being quite filled with milk, and he carries out this part of his invention by means of two lids, the large lid covering the mouth of the can, and the small lid covering a small cup which is fixed upon the top of the large lid. Through the large lid and entering into the small cup there is a tube, through which the milk can pass out of the can into the cup, and out of the cup into the can, thus ensuring the can being quite full of milk, whether the milk be shrinking or expanding from the effects of cold or heat. The large lid is made to fit watertight, by means of a washer of india-rubber fixed upon the collar of the cam or upon the under rim of the lid. The lid is pressed firmly down on the washer by spring catches, hinged on the rim of the lid, and biting under the collar of the can. When used, the can is filled with milk, and the large lid fastened on, the cup is then nearly filled with milk and the smaller lid put on.—Patent abandoned.

86 C. MCDOUGALL and C. H. EDEN, Manchester. *Umbrella and dress suspender.* Dated January 12, 1869.

The inventors take a piece of elastic cord or other similar and suitable material, rather longer than would be required for a dress suspender merely, and provide any ordinary suitable fastening to connect the ends together when placed round the waist. They next provide a plate of metal (or other suitable material) and form therein four, six, or more holes in a line near to each other, and of such diameter that the elastic cord can pass through, but not too easily. They then pass the elastic cord backwards and forwards through these holes alternately, leaving a loop of the same between the two centre holes. This loop forms the umbrella suspender, and may be lengthened or shortened by drawing the elastic cord through the holes. A button or tassel is attached to the loop for facility of drawing out or expanding the loop when the umbrella is to be removed therefrom.—Patent completed.

87 W. E. GEDGE, Strand. *Power looms.* (A communication). Dated January 12, 1869.

This consists in the application of a movable rotary tappet, with single or double hinged stoppieces for preventing milling in power loom weaving.—Patent abandoned.

88 A. HENRY, Edinburgh. *Firearms and cartridges.* Dated January 12, 1869.

The sliding piston which passes through the breech is formed with a bevelled shoulder, which may be either on the side, front or rear of the piston, and which fits into a corresponding recess formed in the breechpiece, of a certain and requisite depth, so that when the shoulder of the piston touches or bears at the instant of firing against the bottom of the recess, the striking or igniting end of the piston is thrown sufficiently far forward to ignite the cap. A bolt or lever passes through the side, front or rear of the breech having a bevelled end corresponding to the bevel on the shoulder of the piston, and the head of the bolt or lever (which is also bevelled) protrudes from the breech when the latter is closed, and passes into a slot in the side, front or rear of the breech cavity. When the breech is withdrawn or lowered, for the purpose of recharging, the side, rear or forward end of the breech cavity acts upon the head of the lever or bolt, pushes it forward, and causes the point to act upon the shoulder of the piston, by which means the piston is drawn or pushed back into the breech into position for firing the next cartridge. The lever or bolt may be arranged either with or without a spring (spiral or flat) upon it.—Patent completed.

89 A. P. PRICE, Lincoln's Inn. *Treating naphthaline* (A communication). Dated January 12, 1869.

This consists in acting upon naphthaline with concentrated sulphuric acid, so as to obtain naphthalic acid. Sulpho-naphthalic acid or salts of the same is then to be subjected to the action of an alkali, such, for example, as caustic soda or potash, at a high temperature, and from the resulting product of the addition of an acid, such, for example, as sulphuric acid, naphthalic alcohol is obtained. The naphthalic alcohol obtained either by this or by other methods is submitted to the action of sulphuric and nitric acids, so as to transform it into duntro-naphthalic alcohol, which product may be employed for the purposes of dyeing and printing. The process is as follows:—About one part by weight of naphthaline is taken, and about one part by weight of concentrated sulphuric acid, and they are heated together at a temperature of about 100deg. Cen. until the greater proportion of the naphthaline has been converted into sulpho-naphthalic acid. This product is then to be dissolved in water, and the solution saturated with an alkali. The salts of sulpho-naphthalic acids thus obtained are evaporated to dryness, and all fused with an alkali, such as caustic potash or soda, or with mixtures of the same, so as to obtain compounds of naphthalic alcohol, which, upon the addition of dilute acid to the aqueous solution, the naphthalic alcohol or naphthol is precipitated and may be obtained in a crystalline form.—Patent completed.

90 B. HUNT, Lincoln's Inn. *Water meters.* (A communication). Dated January 12, 1869.

This consists in so constructing a valve piston or sleeve resting on a ring provided with double inclines that as the water is let in above, the piston or sleeve will be pressed downwards, thus causing a downward spiral movement of the sleeve. The piston or sleeve is provided with slots or ports on its sides, so arranged in relation to ports in a hollow shaft or in an outside cylinder as to change the direction or current of the water from one side to the other of the movable wing in the lower cylinder, whereby a semi-rotating motion is imparted to the shaft, in turn acting upon the cone ring, so as to cause a change in the position of the cone ring relatively to the sleeve or piston.—Patent completed.

91 Sir F. SYKES, Ivenhurst. *Defending forts, &c.* Dated January 12, 1869.

The invention comprises the defending floating or land structures by a curtain or curtains of chain armour, suspended or supported by the structures and clear of the same, and with or without the intervention of packing. An ordinary armour-plated ship when struck by a projectile has to sustain the concussion and entire weight of the same, and, by its non-yielding resistance, to stop the velocity and momentum of the projectile. It is the object of the invention to overcome these disadvantages by the buffer-like effect of the apparatus employed; the resistance employed of itself is or by its suspension or support being of a somewhat yielding character. The attachment and suspension of the armour may be made in any convenient manner. It is preferred to suspend it from davits fixed on hinges to the ship's side, and aided by the ship's rigging (but other means may be employed) in such proportion that should the one half of the davits be damaged in action, the remainder may suffice to sustain the load and strain upon them. In the event of a shot striking the outer suspended curtain of the improved flexible chair armour, the part struck would at once yield to the force expended on it, and the projectile would lose probably half of its effective force, and should it even penetrate the first curtain, it would even then have to encounter other curtains, whose powers of endurance for resisting penetration would prove effectual. The distance of the chain armour from the ship's side should be as far as is consistent with the allowing of three or even four tiers of suspended armour each part from the other. The curtains when not required for action can be stowed in special places in the ship's hold, acting there as ballast, and can be placed easily in position for action by simple machinery. When in action, water can be admitted into tanks in the ship's hold to supply the place of the missing ballast, and it can be pumped out at will when the armour is required to be placed below.—Patent completed.

92 A. V. NEWTON, Chancery-lane. *Knitting machinery.* (A communication). Dated January 12, 1869.

The needles being arranged in vertical recesses formed in the periphery of a fixed cylinder are free to slide up and down therein. At their extremities the shanks of the needles are bent outwards at right angles, and they bear upon a cam groove formed in a rotating cylinder that surrounds the needles. At the upper end of this cylinder is a ring groove, and the cam and ring groove are brought into connection by a vertical groove formed in the inner face of the rotating cylinder. When, therefore, any needle is required to be thrown out of action, the vertical groove is brought opposite that needle, and then by hand the needle is lifted so that its stem may rest in the upper or ring groove. By bringing the vertical groove in succession opposite certain needles (after any desired length of circular knitting has been completed) and then lifting those needles out of action, backward and forward knitting on a limited number of needles may be carried on, the number of needles that are thrown in or out of work being increased or diminished at pleasure.—Patent abandoned.

93 D. L. COATES, Q. DUNLOP and W. ORR, Belfast. *Couplings and wheels.* Dated January 12, 1869.

This consists in imparting elasticity to the joints and wheels of shafting and gearing by means of springs or india-rubber, cork, or other similar elastic substance introduced into either half of the coupling and acted upon by the other half, or between the rim and arms or at the centre of the wheel, in order to equalize the strain, impart a more regular motion, and lessen any shock arising from suddenly increased or diminished velocity in the revolution of the shaft.—Patent abandoned.

94 C. E. BROOMAN, Fleet-street. *Velocipedes.* (A communication). Dated January 12, 1869.

This consists in the application to velocipedes having two, three, or more wheels of mechanism, for the purpose of enabling them to travel with greater rapidity than when the driving wheels are acted upon directly by the feet of the operator. This mechanism consists of a train of cog-wheels, of which, in the case of velocipedes of three wheels, one is fixed to the frame and the other to the axle of the driving wheels, whilst in the case of velocipedes having only two wheels the first cog-wheel is fixed on the frame and the second and smaller cog-wheel is fixed on the axle of the front wheel of the velocipede.—Patent abandoned.

95 G. V. OSBORNE and A. J. PEERLESS, Rahere-street *Ball cocks or valves.* Dated January 12, 1869.

This consists in so constructing a ball valve that the pressure of the water from the main shall assist in opening and closing the sand valve. The inventors propose to effect this in the following manner:—In a suitable casting they adapt a valve formed with a stem, the upper part of which works watertight through a hole in the casting, and the protruding part of the stem is connected to one end of a horizontal vibrating bent lever, to the other end of which a hollow ball of metal is fixed and operated upon by the water in the cistern, in which the ball valve is fixed in the usual way. The diameter of the aforesaid valve is somewhat less than the opening in the casting in which it works, and the valve, which is formed of vulcanized india-rubber, is kept tight by coming into contact with an annular seat at the top of a short outlet pipe, through which the water passes from the water main into the cistern for filling the same, the water entering the valve casting by another short pipe fixed thereto, and to the service pipe, at right angles, or nearly so, to the aforesaid outlet pipe.—Patent completed.

96 H. AITKEN, Falkirk. *Lamps.* Dated January 13, 1869.

This consists in covering the burner with a shade, globe, or box made wholly or partially of glass, and in exhausting the vitiated air and products of combustion therefrom, thereby producing a partial vacuum in the shade, globe or box into which the air necessary to support combustion flows by the pressure of the atmosphere. To effect this a tube or connection is attached to the top of the globe, shade or box, made wholly or partly of glass, in which tube or connection a draught is caused by means of a jet of steam, water, air or gas, or by connecting it to a chimney, condenser, stalk, or boiler, flue, or any other means for producing a draught, may be employed. A metal case is situated on the top of the shade, globe or box in which the air contained is heated, and the heated air is conveyed by tubes to the bottom of the lamp, where it enters the interior of the lamp by a tube or tubes to mix with the gas evolved from the oil and with which it is burnt. The oil for combustion is contained in a reservoir, which is connected by a passage to a secondary reservoir in the bottom of the lamp, from which part it is burnt. The flame of the lamp is conveyed by the ordinary cone hitherto employed.—Patent abandoned.

97 S. JELLYMANN, Cannock. *Reaping machines.* Dated January 13, 1869.

This consists of a horizontal platform or frame, supported

by the road or driving wheel or wheels, and a knife or guide bar at right angles to the platform, in which guide bar the serrated knife or cutter works. The guide bar is supported by a small wheel at its extreme end. The platform or frame described carries the mechanism for giving the reciprocating sliding motion to the serrated knife or cutter. The inventor constructs and arranges the parts for working the serrated knife or cutter from the road or driving wheel or wheels of the reaping and mowing machine in the following manner:—The road or driving wheel supporting the platform or frame of the machine is provided with an external or internal toothed or spur wheel, which gears with a pinion on a shaft or axis parallel with the shaft of the road wheel. On the end of the axis of the pinion is a crank. A connecting rod is jointed at one end to the crank and at its other end to a horizontal sliding bar working in grooves in the frame or platform of the machine, lateral motion in the bar being prevented by the shape of the bar and the grooves in which it works. The sliding bar is not straight, its middle part being inclined to the ends of the bar, that is, the ends of the bar are opposite one another and joined by the inclined part described. By the motion of the cranked and toothed wheels described, a reciprocating sliding motion is given to the bar, which motion is caused to give a reciprocating sliding motion to the serrated knife at right angles to the said bar.—Patent completed.

98 C. J. GUNTHER, Mark-lane. *Preserving meat.* (A communication). Dated January 13, 1869.

This consists in the use of the following formulæ for the preparation of the brine or salt water:—Salt water: Dissolve 36lb. of chloride of sodium (common salt) and ½lb of crystallized phosphate of soda in 10 gallons of water; the addition of phosphate of soda is made with the object of purifying the chloride of sodium from lime and magnesia. When employing sea salt, the quantity of phosphate of soda should be increased to 1lb.; allow the solution to stand until clarified, and then decant the fluid from the white earthy deposit. Brine: The above yields 11½ gallons of salt water, to which add 6lb. of extractum carnis, 1½lb. of chloride of potassium, 10oz. of nitrate of soda. The nitrate of soda serves to colour the meat.—Patent completed.

99 P. M. BARNETT, Aberdeen, N.B. *Securing wooden keys.* Dated January 13, 1869.

In the jaw of the chair between which and the rail the wooden key is placed a vertical groove or channel is formed, which is continued into or through the lower portion or bed of the chair, so as to form a socket therein. The wooden key having been placed in position, an iron key provided with a chisel point is driven into the before-mentioned groove or channel, until its point enters the socket in the lower portion or bed of the chair. As the iron key projects beyond the face of the jaw which contains the groove or channel, the wooden key is thereby compressed, and is, consequently, held firmly in position, and is not liable to displacement and derangement, as is the case with the modes of fixing such keys hitherto in use.—Patent completed.

100 J. STEEL, Glasgow, N.B. *Waterclosets.* Dated January 13, 1869.

A space is enclosed by walls outside the staircase, and is carried up the entire height of the building, or nearly so. This space is partially boarded over, and a closet with a seat is constructed at each flat, but the several closets are arranged so that the space below each seat is perfectly clear down to the bottom. Thus, if the space or shaft enclosed by the walls were continued with the same width up to the top, which could be done if preferred, then the top closet would occupy the whole horizontal area, the next below it would occupy that area diminished by a shaft from the seat above, and the lower ones would occupy spaces diminished by the other shafts, corresponding to the number of shafts above.—Patent completed.

101 L. STERNE, J. A. JAQUES, and J. A. FANSHAWE, Tottenham. *Elastic rubbers.* Dated January 13, 1869.

The inventors combine the soft, porous, spongy rubber with a skeleton or framing of some more solid or rigid substance which will maintain its shape, such, for instance, as solid vulcanized india-rubber or hard rubber.—Patent abandoned.

102 J. PARKER, Camberwell. *Propelling vessels.* Dated January 13, 1869.

This consists, first, in placing upon the surface of the water contained in the tanks or holders a float, by which the steam and air is kept from coming into direct contact with the water, thereby greatly diminishing the loss by condensation, which takes place when the steam and air is allowed to press directly upon the surface of the water. Second, in lining the tanks or holders with one or more substances of small conducting power, for the purpose of diminishing the loss by condensation, which takes place when the steam and air is allowed to come in direct contact with the metallic water tanks or holders. When wood or cork or other porous material is used for the floats, or for the lining of the tanks or holders, the pores thereof are to be filled up with varnish or other suitable substance, to prevent penetration or absorption of steam or water by the float or lining of the water tanks or holders. In some cases it may be desirable to have a thin airtight metallic covering to the lining of the tanks or holders, to prevent the direct contact of the steam and air and water with the lining of the tanks or holders, and also to have a thin metallic covering to the float, to prevent the direct action of the steam and air and water upon the float.—Patent completed.

103 L. HANNART, Clerkenwell. *Moulding dies.* Dated January 13, 1869.

The bottom of the tool constituting this invention consists of a circular flat plate of metal, upon which another circular plate of metal rests loosely, of smaller diameter than the former plate. This smaller plate is formed with a fillet about its upper edge, to serve as a shoulder for the engraved dies to be forced against, and thereby to bring the segmental dies close together, so as to form them into an entire circular die or mould. These segmental dies are each connected by a screw to the bottom plate of the mould, the heads of the screws each taking into an oblique slot or groove formed in the plate. Grooves or slots are also formed in the filleted plate above mentioned, radiating from the centre thereof, and into each of these radial slots a pin takes, one of such pins being fixed into the under side of each segmental die.—Patent completed.

104 J. SCHLOSSER, Frankfort. *Metallic packing.* Dated January 13, 1869.

The improved packing is contained in an ordinary box with its gland connected in the usual way by bolts and nuts. It is composed, in the first place, of an inner metallic shell, divided into two halves, and cast in a particular metallic alloy, which is called anti-friction. Internally, this piece is cylindrical throughout its entire depth, and bored to the same diameter as the rod it is intended to fit externally. Its upper part, which fits in the gland, is conical, whilst its lower part is cylindrical, except at its junction with the conical part, which is also conical. The lower cylindrical part of the shell extends below and beyond the shoulder usually employed to receive a metallic ring, which ring is suppressed in this system. This shell is divided in the direction of its height into two parts.—Patent completed.

105 W. R. LAKE, Chancery-lane. *Uniting ends of tubes.* (A communication). Dated January 13, 1869.

The inventor provides the ends of each pipe or each length or section of pipe with a movable flange, which is kept in place by collars or projections on the end or head of each tube. The collars extend only partially around the tube, and the loose flange is formed with recesses or apertures, which, when brought opposite the collars, will pass over them, and which may be turned partially around behind the collars, the flange being thereby securely held on the pipe. By this means, the flanges may be conveniently placed on the end of the pipe or removed therefrom, and may be adjusted to receive the bolts whereby the pipes are secured together. Between the two pipes or ends to be connected together, the inventor places an annular connecting piece or coupling, which is recessed on each side to receive a ring of india-rubber, or other suitable packing material, against which the end of each pipe is bedded. These connecting pipes are made with their faces either at right angles to the bore of the pipes, or with one face or with both faces oblique or inclined at any desired angle. When these connecting pieces are properly arranged between the ends of the pipes, the loose flanges are connected by the bolts and nuts, and by screwing down the nuts the two ends of the pipe are drawn together and made to bed closely on the packing rings, thereby making the joint perfectly tight and secure.—Patent completed.

106 C. P. COLES, Bonchurch, Isle of Wight. *Protecting ships' bottoms.* Dated January 13, 1869.

This consists in protecting the bottoms of ships or other submerged structures from fouling by the employment of copper or other appropriate metal filings, or a solution of copper or other metals applied to the surface of cements, paints, glues, and other adhesive substances with which the vessel or structure may be coated. The inventor proposes to apply the copper or other metal filings by sprinkling or dredging them on to the soft surface of the cement or paint, and afterwards, if necessary, rolling or pressing them on to that surface, and applies the solution when used with a brush or otherwise.—Patent completed.

107 G. D. KITTOE and P. BROTHERHOOD, Clerkenwell. *Valves.* Dated January 14, 1869.

On the valve, at or near its periphery, the inventors fix a ring or edging of caoutchouc projecting from the face of the valve. This ring or edging is of such a section that its base where it is attached to the valve has considerable breadth, while its summit or that part which, in closing, comes first in contact with the seat, is narrower and rounded. Thus, as the valve closes, the narrow apex of the elastic ring or edging in first meeting the seat yields to the pressure, and, as the valve closes farther, the compressed material presents an increasing breadth for resistance. The elastic edging may be fixed on the seat instead of the valve. The valve or the seat may be either of metal or of hard caoutchouc, such as ebonite or vulcanite. The edging may be fixed either by pitchy or resinous cement, or by suitable flanges, or by moulding it in its soft state into dovetailed recesses, formed in the valve or seat, but it is preferred to fix it during the process of vulcanization.—Patent completed.

108 W. M'DONNELL, Limerick. *Churns.* Dated January 14, 1869.

The inventor takes a pair of rails, the ends of which are turned upwards or somewhat curved, the distance apart being regulated by the width of the churn itself. He thus forms a sort of cradle or frame to support the chain, as hereafter described. These rails are united together by girders or rods having one rod or a framing at or about the centre of the rails, and on which the frame is balanced and free to oscillate. Springs are placed on the ends of a frame, or, in some cases, a spring at one end is sufficient, and in others they may be dispensed with altogether, supporting the rails against which the rods uniting the rails are free to act. In those cases where springs are used, but, where they are dispensed with, the cross rods act as stops to the cradle, a handle or handles is or are used for depressing the rails or for communicating an oscillating motion thereto.—Patent abandoned.

110 J. R. HODGSON, Limehouse, E. *Life buoys.* Dated January 14, 1869.

The inventor constructs a buoy or boat having a central space, the surrounding parts being so formed as to be buoyant, and so prevent the buoy or boat from sinking, and the buoy or boat being so formed as to afford the same means of rescue, whichever way it may be uppermost in the water. The transverse section of the sides and bows of the buoy or boat are preferred to be of a round or curved form. It is preferred to form the ends of the buoy or boat with cutwaters, and such cutwaters may be continued around both ends of the buoy or boat, so as to act as a keel or gunwale, whichever way the buoy or boat may be uppermost in the water. A keel may be continued from end to end of the buoy or boat, and form a central division having a space on either side between it and the sides of the buoy or boat, and such keel may be formed so as to admit water for ballast. Both surfaces of the buoy or boat are provided with ribs or gunwales, which act as keels or gunwales, according to whichever way the buoy or boat may be uppermost in the water. Compartments or receptacles are provided in the sides or other part of the buoy or boat in which to store provisions. These compartments or recesses are, however, simply a matter of convenience, which may be readily arranged according to circumstances. The buoy or boat is surrounded with a rope or chain, which may be flat or round in form, to be used either for the purpose of turning or hoisting the buoy or boat, and belts or ropes are attached thereto to aid in the rescue of persons in the water. In order to protect persons within the buoy or boat, network is provided, preferably in sections, and so arranged as to be capable of travelling fore and aft in "jackstays" and guides.—Patent completed.

111 T. MORTLOCK, Hoxton. *Dressing millstones.* Dated January 14, 1869.

The inventor employs a metal frame, truly planed and faced on the under side, which, when the apparatus is in use, rests on the stone to be operated on, and is there kept in place by its own weight. On the frame a carriage is mounted, and it is capable of sliding along it on guides from end to end, a motion which is given to it by manual labour. The carriage has upon it a toolholder, capable of being traversed across the carriage by a screw. In the toolholder is fixed a tool; it may be a diamond or steel point or cutter, and as the carriage is moved along the frame, the tool traces lines upon the face of the stone. The point or tool is set down to the depth required by a screw, and with the toolholder it is moved a minute distance across the carriage before each forward traverse of the carriage. This motion is given by the screw of the carriage, operated upon by a self-acting ratchet and pawl. Thus it will be seen that at each action the cutter forms a minute and perfectly true groove on the stone, either on the face or in the furrow, as the case may be, and these lines being repeated very close together and parallel the one to the other, the required level and roughened face is given to the stone, and the furrows are made and kept of the proper depth. When one quarter or part of the stone is complete, the frame is shifted on to the next quarter or part, which is similarly operated on, and so the operation goes on until the work on the stone is complete.—Patent completed.

112 E. P. NORTH, Birmingham. *Pocket lamps.* Dated January 14, 1869.

The inventor makes the case of the lamp of a cylindrical figure, an opening being made in one side, through which the light from the candle passes. Upon the cylindrical case a close-fitting cylindrical covering works, which has an opening in it of the shape and size of that in the cylindrical case. At the bottom of the case is a perforated collar, through the sides and end of which air is admitted to the lamp. This collar is situated below the bottom of the covering, which turns upon the collar. A short tube is fixed in the axis of the case, in which the candle tube slides with considerable friction. A disc at the bottom of the candle tube enables it to be raised or lowered in the lamp case to the required extent, and also serves as a foot. The lamp glass is made of a cylindrical figure, and is supported on flanges carried by the lamp case. A lid or cover closes the top of the lamp and carries a double hook, by which the lamp is suspended in the railway carriage. Between the lamp glass and the back of the case a reflector is fitted. When the lamp is in use the close-fitting covering described is so turned that its opening coincides with the opening in the cylindrical case of the lamp. The candle tube is adjusted opposite the opening, and the lid at the top of the lamp is raised. The lid, however, need not be raised when provision is made for the escape of hot air. When it is wished to close the lamp and fit it to be carried in the pocket or portmanteau, the cylindrical covering is turned, so that an unperforated part of it is brought over and made to close the opening in the lamp case and protect the lamp glass from being broken. The lid of the lamp is shut down, and the candle tube is raised in the case until its disc bears against the bottom of the lamp. The lamp now resembles a tube closed at both ends. It occupies little space, and may be carried in the pocket or portmanteau without inconvenience and without danger of breaking the lamp glass. A handle may be fixed to the lamp so as to allow of the lamp being used as a hand lamp or lantern.—Patent completed.

113 H. VAVASSEUR and C. M. WADE, Furnival's Inn, E.C. *Permanent way.* (A communication). Dated January 14, 1869.

The key or wedge is formed of sheet metal coiled or bent up into a suitable form to enter the space between the chair and the rails, and when driven up as an ordinary key or wedge to hold the rail firmly in position. This description of key or wedge is formed of metal of a width corresponding to the length or width of the desired key or wedge. By these means an elastic wedge or key is formed which is not injuriously affected by climate or insects.—Patent completed.

114 A. V. NEWTON, Chancery-lane. *Reaping and mowing.* (A communication). Dated January 14, 1869.

The main frame of the machine is constructed in one piece, having an axle on one side for the driving wheel, and on the other side a hollow cylindrical arm or projection which serves to support the gearing, and as a point of attachment for the tongue frame and crank or cutter frame. The bevel wheel shaft is supported by a pipe box inserted in the chamber of the cylindrical part of the main frame and retained in position therein by a single bolt passing through a flange in the box and through the main frame. The shaft is formed with a collar, which, with the bevel wheel on the other end of the shaft, serves to prevent end play in the pipe box. The pinion is placed loosely on the end of a shaft outside the collar, and is recessed on its outer face for locking with the pin in the end of the shaft. It has also a groove formed in the periphery of its hub in which a fork connected by a spring to the main frame is inserted, so that the recoil of the spring will keep the pinion against the collar at all times when not forced outward by the pivoted vibrating wedge through which the pinion is made to lock with the pin in the shaft at the pleasure of the operator. The pinion gears with the teeth of the gear rim on the driving wheel and receives its motion therefrom. The tongue frame has a recess on its under side to receive the tongue, and an eye or sleeve at its rear end embracing and uniting it to the cylindrical arm or projection of the main frame, forming a hinge connection therewith. On the side of the tongue frame is mounted a spur pinion secured in proper bearings, and having an axle projecting from its casing for receiving a lever or wrench for turning it. This pinion gears into a sector rack on the front end of the main frame, so that any motion given to the pinion imparts a corresponding motion to the main and tongue frames, the axial centres of movement of said frames being coincident with the centre of the bevel wheel shaft. A dog or button is provided for locking the two frames in any desired relation to each other.—Patent completed.

115 W. E. NEWTON, Chancery-lane. *Steam pumps.* (A communication). Dated January 14, 1869.

This consists in providing a cylinder and piston which are in communication with the air chamber, or with any pipe or vessel from which the pressure of the water produced by the pumping engine may be made to act on the piston of a small additional regulating cylinder. The rod of this piston is connected by a link motion to, and made to operate the induction valve of, the engine, so as to shut

off or let on the steam as may be required. A coiled spring will keep the regulating piston down, so that when the pressure of the water is removed from its under side the piston will be forced down, and will thereby cut off the steam from the engine, but when the pump is at work it will force up the piston and compress the spring, thereby opening the induction valve and allowing steam to enter the cylinder of the engine.—Patent abandoned.

116 J. H. Kitson and J. Kirby, Leeds. *Movable grates.* Dated January 14, 1869.

This consists in adapting to steam boiler and other furnaces movable grates composed of separate transverse firebars which are caused to travel along the furnace from end to end on an upper tier or guide at an uniform speed depending upon the rate of combustion required. When such bars have travelled the whole length of the upper tier or guide they are caused to fall on to a lower tier or guide on which they are returned to the end from which they started, and when there they are lifted up to the upper tier so as to be carried forward a second time. All the bars will thus be made to perform an endless circuit and be constantly moving forward.—Patent completed.

117 T. Cook and J. Watson, Victoria Chambers, S.W. *Oil presses.* Dated January 14, 1869.

This consists in certain novel and improved mechanical arrangements and combinations constituting a press suitable for expressing oil from seed or other oil-yielding substances. The inventors form a deep but narrow box with strainers of novel and peculiar construction of the entire width and depth of the box. To the bottom of the box they adapt a sliding or false bottom so arranged as to be capable of being easily removed after the seed or other oil-yielding substances have been sufficiently compressed to allow the compressed residuary matters or cake to be forced out of the box into a receptacle below. Above the box they place a steam cylinder of considerable dimensions, resting on two or more columns, and fitted with a piston rod or plunger formed of a flat piece of steel or other metal exactly fitting into the aforesaid box. The piston rod or plunger works through a slot formed in the cylinder bottom, and the said piston rod or plunger should be so arranged that it can be passed into and through the aforesaid box at the will of the operator.—Patent completed.

118 A. M. Clark, Chancery-lane. *Firearms and cartridges.* (A communication). Dated January 14, 1869.

The improvements in firearms consist, first, in making the end of the extractor groove extending the whole length of the breech chamber, at one side to terminate in a recess to receive the end of the spring acting cartridge extractor. The recess being made in the shoulder formed at the junction of the bore and breech chamber, no space is required for receiving the extractor at that point, which space is liable to burst the cartridge in firing. Second, the inventor makes on the opposite side of the breech chamber a shallow recess to receive a portion of the rim of the cartridge case when drawn back by the extractor. The improved metallic cartridges consists, first, of a head of copper thinned round the edge in order to prevent its cutting the case containing the powder from the internal pressure produced by the explosion. The inventor forms the rim by the aid of pressure, so as to bring the two surfaces together and prevent the gases from entering and bursting the rim. Second, of a tube composed of thin sheet copper coiled on a mandril of suitable diameter, and then covered with paper pasted on to prevent the copper from uncoiling. Third, of a cylinder or wad of compressed pasteboard serving to close the end of the cartridge, and for connecting the copper cap and tube. The cap is sometimes of conical form, in consequence of which the pressure of the wad ensures a tight fit between the cap and the tube; but when the cap is cylindrical, in order to secure the parts together, the inventor pierces holes in the cap into which the tube and pasteboard wad are forced, forming so many tongues for connecting the parts.—Patent completed.

119 T. Birkett and H. Scott, Birmingham. *Breech-loaders.* Dated January 14, 1869.

This consists in providing two, three, or more separate spring bolts or catches, so arranged that the bolt or catch on which the hand lever directly acts, in turn acts upon the next bolt or catch, and so on throughout the series, if more than two bolts or catches be employed. The inventors prefer to use three bolts or catches arranged as follows:—The locking lump on the under side of the barrels is divided transversely into two parts, entering two separate corresponding recesses one behind the other in the body. The first spring catch or bolt is fitted into the body to work in a hole or passage formed for it in the metal which separates the two recesses already mentioned. The hand lever works on a transverse horizontal axis under the body, and a spring which acts upon it causes an arm with which it is provided to push forward the first bolt or catch, to cause its nose to enter a notch in the back of the front portion of the locking lump. The nose of the catch is inclined, so that it yields to the lump and lets it pass as the barrels are closed. The second catch is on the hindermost of the two parts of the lump on the barrels, and it locks into the partition between the two recesses in the body. The third catch is in the body at the back of the second recess; it is provided with a spring to throw it forward, and it catches into the back of the hindermost part of the lump on the barrels.—Patent abandoned.

120 H. L. Harris, Somerset-street, E.C. *Packing cases.* Dated January 15, 1869.

This consists in making the ends or sides of boxes, cases, or trunks deeper than usual, thereby causing the top and bottom to be fitted on and fixed in their place. The nails are driven transversely, that is to say, at right angles to each other in every edge of the case or box, but the mouth or opening of the trunk will be lined inside.—Patent abandoned.

121 C. H. Lea, Stafford. *Railway signals.* Dated January 15, 1869.

This relates to former letters patent, granted March 9, 1863, No. 651. The improved apparatus for opening and closing railway crossing gates consists principally of two levers, connected to a hand lever by a rod. The two levers meet at their inner ends in the centre of the railway line, and are connected together by a slotted eye and pin, or other equivalent; the outer end of each line is jointed to two connecting rods, each rod being in communication with an arm lever fixed on the gate heel, with which it communicates. The connecting rods have adjusting screws placed on them to regulate each of the gates; the lever in connection with the hand lever has its outer end lengthened, to which the rod leading to the hand lever is attached. By this apparatus all the gates are caused to act simultaneously. If it is a single line where the crossing is situated, one lever is all that will be required, instead of the two above mentioned in connection with the hand lever, the gates further away or nearer to each other as occasion may require, so as to prevent them from meeting in the centre. The top centre arm of the gate is also fitted with adjusting screws and plates (one of which is fitted in the post, and has indentations formed in it, the other having projections formed on it, which fit into the plate in the post) for raising and lowering the gates, and so prevent them from trailing on the ground. Guards are also fitted on the heels of the gates to keep them from damage, from stones, ballast, or dirt getting inside and preventing the free working of the gates.—Patent completed.

122 J. Steel, Glasgow. *Cleansing casks.* Dated January 15, 1869.

The machine consists of a large disc or chuck fixed on the overhanging end of a horizontal shaft, made to revolve backwards or forwards at any convenient speed by means of gearing. A series of cradles to receive the casks are arranged with their axes tangent to a circle on the face of the disc, and are mounted on journals connected by bevel wheels with each other. The casks are placed in the cradles with their axes coinciding with the journals, and when the machine is in action each has a rotation about its own axis combined with the motion due to being carried round by the rotating disc. There may be a single disc on the shaft, or there may be two such discs thereon, one on each end, and they may be provided with cradles for different sizes of casks. The gearing for imparting the axial rotation consists in the case of each disc of a bevel toothed ring encircling the main shaft, but fixed to the framing, and having in gear with it a bevel wheel on a radially disposed shaft carried upon the disc. This radial shaft rotates in consequence of being carried round by the disc and of the bevel pinion, consequently rolling round the ring, and it imparts motion by bevel gearing to one of the cradle journals. This gearing consists of a bevel wheel on the outer end of the radial shaft in gear with a bevel wheel on a short shaft, carried by the disc, and having on its other end a bevel wheel gearing directly with one of the bevel wheels.—Patent completed.

123 A. de P. Chance, Birmingham. *Step ladders.* (A communication). Dated January 15, 1869.

The sides are formed in pairs of bars of angle iron, or other suitable metal or metals, jointed together by means of a pin or otherwise, the bars on each side being connected together at their upper and lower ends by horizontal rods. The bars of angle iron or other metal or metals when opened out on their joints form an X at each side of the step ladder. To the horizontal rods at the upper part of the bars are connected by collars jointed metal straps, to which are fastened two boards, one on each side of the joints. By means of the metal straps and the before-named horizontal rods, a frame is constituted capable of supporting the said boards, which form the top of the step ladder, and when the sides are opened out afford a stand or top step. To the outside inclined bars are suspended (by means of metal straps with ears or lugs, capable of turning on pins in the said bars), two boards, one under the other, connected together by metal straps, moving on pins at their ends. By this means the two boards form the two lower steps of the ladder, and from the arrangement of the metal straps and the inclined side bars they are firmly supported, so as to become capable of bearing weights as required.—Patent abandoned.

124 J. T. Smith, Barrow-in-Furness. *Converting vessels.* Dated January 15, 1868.

This consists in making the bottom of the converting vessel of wrought iron or steel instead of fireclay or other non-metallic material, the bottom being flush with the fireclay lining of the sides of the converting vessel, and forming the top of a short hollow cylinder secured by riveting or otherwise to the outer metallic portion of the converting vessel. The blast of air is delivered through the metallic bottom by means of a series of metallic pipes fed through one of the trunnions of the converting vessel in the usual way. In order to keep the metallic bottom cool, and prevent its fusion or the attachment of the molten iron or steel in the converting vessel thereto, the inventor applies water to the under side of the bottom in the following manner:—A series of concentric tubular rings are supported at a short distance below the metallic bottom. These rings are connected through one of the trunnions of the converting vessel with a reservoir of water, which water is supplied to the said rings under considerable pressure. Through small holes in the upper sides of the said rings a series of minute jets of water are delivered on the under side of the metallic bottom, which is thus kept cool and uninjured by the heat to which it is exposed.—Patent abandoned.

125 H. Fowkes, Manchester. *Cleaning rod.* Dated January 15, 1869.

This consists in the novel employment and use of a stick or rod, the length of which is somewhat greater than the gun barrel it is designed to clean. The lower end of this rod is formed with a hollow cylindrical recess, into which is placed a spiral brush or other expanding material connected with a sliding rod passing up the centre or core of the first rod, and terminating in a knob or handle outside a distance equal to the length of the cylindrical recess formed in the bottom of the larger rod. Thus, when it is desired to clean the gun barrel, the rod containing the spiral brush or other suitable expanding material is inserted in the barrel up to the breech, at which time the central sliding rod, to which the spiral brush is attached, is held whilst the rod with its cylindrical end is withdrawn, the action of which forces the brush from the cylindrical recess, causing it thereby to expand and press upon the interior surface of the gun barrel containing it, which, when being withdrawn, thoroughly and effectually cleanses the barrel from all foul or extraneous matter.—Patent abandoned.

126 D. P. Wright, Birmingham. *Window blinds.* Dated January 15, 1869.

This consists, first, in making blind rollers of wood in two parts, that is to say, using a strip of wood of a semicircular or other convenient form, with a semicircular or other shaped groove on the flat sides, and by cutting off strips so formed in suitable lengths, using two of such pieces or lengths for a roller, and securing them together by glue or other means. The internal groove will be continuous and uniform from end to end, with an open joint sufficiently apart to allow the fabric or material of the blind to pass between in the following manner:—A broad hem is formed on the top of the blind, into which a strip of wood or other suitable material may be inserted, sliding the same with the blind into the groove of the roller from the end, an opening being formed in the single-flanged metal end for allowing the blind proper to pass in, and securing such end by screwing in the ordinary way, and the other metal end has a sunken groove or double flanges, which metal end it is preferred to put together in parts, produced partly by casting, drawing, and pressing, and fixed together with press tools, to which a single elevating blind cord is connected and wound around the same by the drawing down of the blind, the metal ends having projecting centres in the ordinary way, working in brackets formed on the window frame.—Patent completed.

127 W. Tijou and W. Whieldon, Westminster Bridge-road. *Getting coal.* Dated January 15, 1869.

It is proposed to break down the coal, stone, or other mineral after it has been undercut in the usual or other manner by inserting into a slot hole, drilled in any convenient or suitable part of the coal, stone, or other mineral, a contrivance consisting essentially of one or more series or rows of levers or arms having a toggle or knee-joint expansive action in a lateral direction, so as to exert a forcible pressure in opposite directions against the walls or sides of the "shot hole," whereby the mass of coal, stone, or other mineral will be effectually broken down. The expansive action of the levers or arms above referred to may be effected in various ways, as, for example, by moving longitudinally, either inwards or outwards, a rod or bar upon which such levers take their bearings, the requisite power being obtained either by hydraulic jacks, screws, or other well-known mechanical contrivance.—Patent abandoned.

128 A. Sehet, Paris. *Breech-loaders.* Dated January 15, 1869.

The breechblock forms the end of an arm or lever which turns on an axis at the rear end of the breech chamber, and is capable of being raised in a vertical direction, so as to uncover the mouth of the chamber for the admission of the cartridge. The chamber is again closed on the block and breechpiece being depressed, and the breechpiece is held fast in position by means of shoulders placed on each side of the breechblock. The breechblock is of a wedge-like form, the sides being parallel to the triangle formed in front by the mouth of the breech chamber, and in the rear by the curve of the two shoulders. The form of the breechblock may be varied, and it may be made with parallel and concentric curves, or may be triangular, with straight or curved sides. A movable piston is placed in the breech chamber, and, by means of a cocking piece, which passes through a slot in the bottom of the chamber, is capable of being withdrawn towards the butt end of the gun, thereby compressing a spiral spring, which is placed in the interior of the chamber, and bringing the sear spring into operation, thus cocking the gun. A needle is fixed to the piston, and is adapted to pass through a hole in the centre of the breechpiece and penetrate to the centre of the barrel.—Patent abandoned.

129 W. H. Brookes, Sheffield. *Door fastener.* (A communication). Dated January 15, 1869.

This fastener consists of a metal shank, about 1in. in length, ⅛in. in breadth, and 1-16in. in thickness, and split at one end, which is turned at right angles to the rest of the shank. The other end of the shank is also turned up and rounded, so as to fit into a recess formed in a button, to which it is attached by a pin. The fastener is used by putting the shank in between the door and the door jamb (with the split end of the shank towards the door jamb) so that when the door is shut the split end of the shank is forced into the door jamb, and the button being turned the door is made fast from the inside. The fastener, when applied to a window, is forced between the sash and frame in like manner.—Patent abandoned.

130 J. Spence, Manchester. *Sulphate of potash.* Dated January 15, 1869.

This invention is carried out by taking the muriate of potash and treating it with an excess of sulphuric acid, and it is preferred that this excess should be about 50 per cent. above its combining quantity. The boiling or heating is conducted into a vessel similar to that which is used in the manufacture of chlorine from hydrochloric acid and peroxide of manganese, the heating medium being a jet or jets of steam, and the operation is continued from three to five hours, or until the whole of the muriatic acid is driven off. The resulting solution, which now contains sulphate of potash and free sulphuric acid, is run into vessels, where shale or other aluminous matters are being or are to be boiled with sulphuric acid, and the free acid in the solution becomes available for combining with alumina, and the sulphate of potash enters into combination with the solution of sulphate of alumina to form alum, as is well known.—Patent completed.

131 T. Howcroft and A. M'Gregor, Bedford Leigh. *Reapers and mowers.* Dated January 15, 1869.

This relates, first, to reaping machines having one main driving wheel. The gearing actuating the knives is contained within, and shielded by a dome-shaped cover or case, in the centre of which the main axle is firmly keyed or fixed; this dome-shaped cover or case has an internal spur wheel cast on or bolted to the inner face of its outer rim, immediately under or inside the revolving circular plate that covers it. This revolving circular plate is free to turn on the main axle, and the main driving wheel is free to turn on the boss or nave of the revolving circular plate. This boss or nave is of sufficient length to carry an ordinary clutch gear, by which the main driving wheel and the revolving circular plate can at once be connected or disconnected; when disconnected, the driving wheel alone revolves, and when connected, the gearing receives motion through the revolving circular plate. This plate carries one or (by preference) two wheels, at such a distance from the internal spur wheel that they work into it, and at the same time, into a pinion on the boss or nave of the large bevelled wheel, which bevel wheel and pinion turn freely on the main axle, and are shielded within the dome-shaped cover or case; the bevel wheel gives motion to a bevel pinion on an inclined shaft, which, through the medium of a crank pin and connecting rod at its lower end, gives motion to the knife bar. The inclined shaft turns in a long bearing or pipe, bushed at its two ends, which bearing or pipe is cast to the dome-shaped cover or case, and forms part of the framework, the latter being curved outwards to allow the inclined shaft to pass under the

main axle; the shafts are attached to the machines by wrought-iron arms, which move freely on the main axle, and the patentees attach a lever to the shafts, by which the cutter bar can be raised or lowered at pleasure, whether the machine is at work or not.—Patent completed.

132 E. CRADDOCK, Camberwell. *Punching metals.* Dated January 15, 1869.

To a suitably shaped body made of metal are connected two metallic arms, one of them being fixed to the upper part of the body (or it may be cast or made in one piece with it), and the other (which is movable) is secured to a quick-threaded screw passing through the centre of the body of the apparatus to the lower extremity of which screw a punch is firmly secured. At the outer end of each arm is fitted a jaw or joint, made capable of revolving, and in each jaw or joint a stud or nut is placed, which is also made capable of revolving. A screw or circular piece of steel, one-half of which is threaded as a right hand screw and the other half as a left hand screw, is passed through the studs, one end being so formed as to allow a handle or key to be fitted thereon to operate the screw. On the screw being turned by the handle or key, the double action of the screw causes the movable arm to approach to or recede from the other arm, and causes the punch to be forced down by means of the quick threaded screw secured to the movable arm, and to it, thereby causing the desired punch or perforation to be made in the metal submitted to the operation.—Patent completed.

133 M. BOYCE, Abchurch-lane. *Whist scores.* Dated January 15, 1869.

This consists of a box, case, or frame holding or wherein is affixed or delineated one set of markers, symbols, or contrivances for scoring. This box, case, or frame being provided with a sliding cover, which when drawn out to a suitable extent exposes to view a marker, symbol or contrivance indicating a score of one, then when farther drawn out, exposes to view another marker, symbol, or contrivance, thereby indicating a score of two, and so on, until that particular set of markers, symbols, or contrivances is exhausted. In the sliding cover of this box, case, or frame there is a recess formed, in which is placed or fixed another set of markers, symbols, or contrivances, and this recess is provided with a sliding cover which operates in a manner similar to the cover first described.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated August 3, 1869.

2319 J. Pinchbeck, Whiskin-street, Clerkenwell, Middlesex. Improvements in gas meters.

2320 H. Turner, Hazel House, Plaistow, Essex. Improvements in high and low pressure expansive condensing steam engines for marine and other purposes.

2321 C. D. Abel, Southampton-buildings, Chancery-lane. Improved mechanism for converting reciprocating rectilinear motion into rotary motion, and for converting rotary motion into reciprocating rectilinear motion.

2322 E. Beanes, Cordwalles, near Maidenhead, Berks. An improved process for re-working wrought iron.

2323 A. Louden, Ceres, Fifeshire. Improvements in taps or cocks used for drawing off water and other liquids from casks or other vessels.

2324 T. Grace, Bristol. Improved apparatus for stoppering bottles.

2325 W. E. Gedge, Wellington-street, Strand. An improved curry comb.

2326 C. Tuer, R. Howarth, and J. Pimbley, Farnworth, Lancashire. Improvements in machines for polishing threads.

2327 J. T. Way, Russell-road, Kensington, Middlesex. Improvements in the manufacture of manures and in the purification of gas.

2328 J. T. Way, Russell-road, Kensington, Middlesex. Improvements in the manufacture of soap, and in cleansing wool and woollen goods.

2329 J. Bapty and A. Hall, Massachusetts, U.S.A. A new and useful improvement in mechanism for spinning wool or other fibrous matters.

2330 I. Davies, Harborne, Staffordshire. Improvements in rotary gas exhausters.

Dated August 4, 1869.

2331 T. Livesey and T. Abbott, Blackburn, Lancashire. An improved mode of boiling size, and in the apparatus employed therein.

2332 E. H. de Bodmer, Boulevart de Strasbourg, Paris. A new kind of carriage wheels with springy spokes and eccentric nave.

2333 F. C. Colney, Boulevard Bonne Nouvelle, Paris. Improved mechanism for the propulsion of vehicles.

2334 G. Broadhurst, Manchester. Improvements in waterproof capes, cloaks, and leggings.

2335 G. S. Hazlehurst, Runcorn, Chester. Improvements in mechanism or apparatus to be employed as a medium of communication between passengers, guard, and engine driver on railway trains.

2336 J. Booth, Shipley, Yorkshire, and R. W. Morrell, Bradford, Yorkshire. A new or improved textile fabric.

2337 W. T. Ramshill, Abinger-road, Deptford, Kent. Improvements in the construction of heels for boots and shoes.

2338 G. C. Ramsay, Aldermanbury, Middlesex. Improvements in circular boxes.

2339 J. Taylor, Herne Bay, Kent. An improved attachment or device for balancing toilet and other looking glasses.

Dated August 5, 1869.

2340 A. Tylor, Newgate-street, City. Improvements in apparatus for regulating, adjusting, and comparing the standards of measures.

2341 J. Elce and R. Bond, Manchester. Certain improvements in self-acting temples for looms.

2342 W. Brown, Smethwick, Staffordshire. Improvements in machinery for rolling rails and girders, and other sections of iron and steel and other metals.

2343 G. W. Murray and G. M. Garrard, Banff Foundry, Banff, North Britain. Improvements in means or apparatus employed in ploughing and tilling land.

2344 J. U. Fairbairn, Southampton, Hants. Improvements in the construction of velocipedes.

2345 E. Beanes, Cordwalles, near Maidenhead, Berks. Improvements in preserving articles of food.

2346 B. J. B. Mills, Southampton-buildings, Chancery-lane. Improvements in meters for measuring liquids and gases.

Dated August 6, 1869.

2347 E. Cocking, Bradford, Yorkshire. Improvements in the construction of easy chairs, and in the ornamental nails for the upholstery of the said chairs, which said improvements, wholly and separately, are also applicable to reclining seats, couches, wheel chairs, and other articles of furniture.

2348 E. Rihoux, Paliseul, Luxembourg, Belgium. A life-preserving dress.

2349 J. and A. Garde, Boulevard Bonne Nouvelle, Paris. An improved ventilating hat.

2350 B. Hunt, Serle-street, Lincoln's Inn. A new or improved numbering register or apparatus.

2351 W. B. Rust, Sheffield. An improved portfolio or case for the preservation of letters and documents in an alphabetical or other orderly manner.

2352 C. J. Chubb, Endsleigh-street, Tavistock-square, Middlesex. Improvements in drills and apparatus for boring holes in coal, hard ground, slate, and minerals.

2353 T. Leach, Tramere, Chester. An improved composition for coating the bottoms of iron ships and other navigable vessels, and marine works, to preserve the same and prevent the adhesion of animal and vegetable matter thereto.

2354 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in devices for holding the chimneys of gas burners and other lighting apparatus.

2355 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in expanding drills for boring rocks.

Dated August 7, 1869.

2356 W. Tongue, Brixton, Surrey. Improved means, apparatus, and machinery for generating elastic vapours and applying such vapours for producing motive power.

2357 E. W. Hawes, Balmoral Lodge, Clontarf, Dublin. Improvements in the construction of buoys and other floating sea-marks.

2358 W. Manwaring, Britannia Works, Banbury, Oxon. Improvements in harvesting machines.

2359 D. Ridge, Smethwick, Staffordshire. An eccentric lever polygonal boring brace, to be used in place or in lieu of the ordinary ratchet brace.

2360 G. Nickerson, Barningham, Suffolk. Improvements in apparatus for raising and stacking straw and other agricultural produce.

2361 W. Guest, Ardwick, Manchester. Improvements in clearers used in machinery for preparing and spinning cotton and other fibrous materials.

2362 H. Brandreth, Manchester. An improved arrangement and construction of cutter to be employed in the manufacture of saw handles and other articles of a similar description.

2363 I. Brown, Elm Croft Grange, Edinburgh. Improvements in irrigating and manuring land, and in the apparatus or means employed therefor.

2364 W. E. Newton, Chancery-lane. An improved process for purifying or disinfecting alcohol and alcoholic liquors.

2365 J. Mitchell and T. Settle, Bolton, Lancashire. Improvements in the manufacture of Marseilles quilts.

2366 A. B. Ibbotson, Sheffield. Improvements in joints for uniting and securing the ends of railway rails.

2367 W. R. Lake, Southampton-buildings, Chancery-lane. An improved machine for sowing and covering seed and for cultivating land.

2368 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for combing fibrous materials.

2369 J. T. Greenfield, Pencester-street, Dover. Improvements in life buoys.

2370 G. Ritchie, Belmont Villa, Tyrwhitt-road, Lewisham-road, Kent. Improvements in the construction of tents and sunshades or weather protectors suitable for carriages and other vehicles.

2371 A. C. F. Franklin, Abingdon-street, Westminster. Improvements in bearings and lubricating apparatus for screw propeller and other revolving shafts.

Dated August 9, 1868.

2372 G. Rastall, Manchester. Improvements in velocipedes.

2373 J. Quinton, Moorgate-street, City. An improved tobacco pouch.

2374 S. Osborn, Sheffield. Improvements in knives and knife bars for reaping and mowing machines.

2375 J. Staniar and S. Dawson, Manchester, and E. Davies, Birmingham. An improved arrangement of mechanism or apparatus to be employed for the purpose of dressing or distributing the different qualities of ground or pulverized grain into compartments or chambers.

2376 J. Froggat, Lenton, Nottinghamshire. Improvements in pickers employed in the process of weaving.

2377 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of felted fabrics, and in the application of such fabrics to the manufacture of hats and other useful purposes.

2378 C. E. Brooman, Fleet-street, City, patent agent. Improvements in means or apparatus for carrying or storing eggs.

2379 A. Turner, Leicester. Improvements in utilizing waste strips of india-rubber, and in machinery for cutting sheet rubber into thread.

2380 H. Wimshurst, Attenburg-terrace, Wandsworth-road, Surrey. Improvements in marine propellers, and in vessels to receive the same.

2381 G. F. Ansell, Bernard-street, Russell-square, Middlesex. Improvements in the manufacture of iron and steel.

2382 W. R. Lake, Southampton-buildings, Chancery-lane. An improved apparatus for adding numbers.

PROVISIONAL PROTECTION FOR SIX MONTHS

Has been granted upon Specifications bearing the following uumbers:—

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, AUGUST 20, 1869.

THE BRITISH ASSOCIATION, 1869.

THE history of the British Association for the Advancement of Science has been so frequently given in the pages of the MECHANICS' MAGAZINE, and is now so well known to all who take an interest in science, that it would be superfluous here to repeat it. The present is the thirty-ninth annual congress of the Association, and its career has been one continued practical comment upon its name. It has ever sought the advancement of science, not merely by annual gatherings and the reading and discussion of papers, but by substantially aiding the development of science by monetary grants. The first three years of its existence were not, indeed, marked by this feature, but subsequent years have been and still continue to be thus distinguished. Sir David Brewster, the venerated "father of the Association," as he is justly termed, proposed at the first to work without corporate funds or outlay, beyond that attending the immediate purposes of the annual gatherings. But it soon became clear that the Association, to be of practical benefit to science, must work upon other principles. This it did, and in the fourth year of its existence—1834—it made its first modest grant of £20 to science. The next year, however, £167 was applied to that purpose, and this amount went on gradually increasing until in 1839, at the Birmingham meeting, £1,595 was granted. The largest grant ever made was at the Norwich meeting last year, when £1,940 was the amount allotted. Altogether, since 1834, upwards of £32,000 has been granted by the Association for the carrying out of scientific objects outside the operations of its own annual meetings. Such have been the popularity and success of the meetings, and such the impetus given to all departments of inquiry—chemical, astronomical, geological, geographical, and statistical—that money has flowed freely into the coffers of the Society. Had the Association done nothing more than produce its wonderful astronomical catalogue, its elaborate meteorological and magnetic observations, and its contributions to various abstruse departments of mathematical and physical science, it would have been fully entitled to take rank as a great national institute. But it has done far more than this; it has, on several occasions, stimulated the Government and Parliament of the country to put forth efforts in behalf of great scientific and humane enterprises.

Various towns and cities have at various times had the honour of receiving the British Association, some of them more than once. It is now the turn of the good old city of Exeter to do honour to and to be honoured by the assembling of the *savants* of the present day. And the visit of the Association is the more opportune and appropriate inasmuch as there are two scientific institutions just ready for opening. These are the Albert Memorial Museum and the Victoria Hall of Science. These buildings will be inaugurated upon the present occasion, and will thus be for generations to come associated with the visit of the men of science in 1869 to the city which they grace. It is now more than three years and a half since the first step was taken in Exeter which led to the holding of the Science Congress of 1869 in that city. The originator of the movement was Mr. H. S. Ellis, of Fair Park, who, in January, 1866, started the proposal to invite the Association to meet in Exeter. In last November, when the invitation had been accepted and preparations were making to entertain the learned guests, Mr. Ellis was elected mayor of the city by common consent, as a fitting recognition of his exertions to bring so much honour to Exeter. The executive local committee consists of the following gentlemen:—Dr. Blackall, Messrs. S. S. Bastard, W. Buckingham, Lieut.-Colonel Brent, Messrs. W. Cann, John Daw, R. R. M. Daw, W. S. M. D'Urban, G. T. Donisthorpe, Rev. W. David, Messrs. C. J. Follett, A. H. A. Hamilton, Joseph Harding, J. Hayward, R. T. Head, R. W. Head, Kent Kingdon, R. M. Lingwood, W. Mortimer, C. H. Roper, E. A. Saunders, Dr. Scott, Messrs. C. L. M. Teesdale, J. Trehane, Charles Tucker, H. D. Thomas, C. A. W. Troyte, J. E. C. Walkey, C. Wescomb, and the hon. treasurers and hon. secretaries *ex officio*. These were subdivided into finance, buildings, conversazione, lodgings, and railways and excursions committees. The labours of these gentlemen to promote the interests and welfare of the visitors, and to give the Association a fitting reception, have been most untiring, and will assuredly render the meeting of the British Association in Exeter in 1869 a complete success.

THE GOLD COINAGE OF ENGLAND.

IT was intended that the fallacy of Mr. Lowe's proposition for reducing the weight of the sovereign without reducing its value should be demonstrated in our columns this week. Since our last issue, however, Mr. Hubbard, through the medium of the "Times," has so completely forestalled us that it is unnecessary to carry out our plan. We need not attempt to "slay the slain," and, no doubt, the Chancellor of the Exchequer himself now wishes that he had not entered the lists in the teeth of so many unknown but doughty knights. Mr. Hubbard's statements are positively fatal to Mr. Lowe's arguments, but the illustrative experiment introduced at the close of the Bank director's letter closes the ground over those arguments. They are now dead and buried, past hope of resurrection. Mr. Hubbard thus inflicts the deadly blow. "They hold," that is Mr. Lowe and his backers—the Master of the Mint and Col. Smith—"that a coinage charge enhances the value of a coin. English sovereigns are coined free, Australian sovereigns are coined at a charge of one per cent. for coinage. They value, therefore, 100,500 Australian sovereigns for 100,000 English. I propose to meet Australia half way and deliver to Mr. Smith or Col. Smith, at Madras or Bombay, 100,000 Australian sovereigns for 100,000 English sovereigns. We shall each hope to gain 500 sovereigns. The operation, if satisfactory, can be repeated, and the result shall be duly reported to the Chancellor of the Exchequer." If this be not a fair sample of the destruction of a sophism by the process known as that of the *reductio ad absurdum* we are much mistaken. The next time Mr. Lowe submits himself to a "cramming" operation let us hope that his "crammers" may better understand what they are about, and not place him and themselves in so humiliating a position as they now occupy.

The weight of the English sovereign must on no account be interfered with, whether its standard of fineness be touched—and this is to be deprecated—or not. The probability is that no more will be heard, officially, of Mr. Lowe's wild and impracticable scheme of debasement. A far more practical consideration in reference to the gold coinage of England than the lessening of the weight of individual pieces, is that of increasing their durability. Mr. Lowe has stated, on the authority of Mr. Jevons, that the average length of the life of an English sovereign is eighteen years. After that time wear and tear have so told upon its constitution that when "weighed in the balance" it is inevitably "found wanting," and is doomed to be remelted. It has been already shown in these columns that very great pains are taken at the Mint to produce sovereigns of nearly equal and true standard weight, and that in reality those issued to the Bank are virtually correct, when dealt with in sensible quantities. Another very important question is, Are they manufactured in such a way as to give them the maximum of resisting power to the abrading influences they will have to encounter? Is it not rather the truth that those parts of the coin which are to be brought into immediate contact with the hard surfaces of tables and counters are soft, and easily wearable, and that they must be reduced very quickly by force of attrition? It will be perceived that this latter question cannot be answered other than in the affirmative, and that the former must receive a negative reply.

Gold coins obtain their impressions by pressure, just as sealing wax is ornamented by the forcible application of a stamp. In order to make the gold discs impressionable they have to be softened by heating in an oven, or annealed, as the technical term is. When this has been accomplished they are placed between dies and struck. The striking depresses and hardens those parts of the embryo sovereigns which do not require hardening, and leaves prominent and soft (by annealing) those which will have to sustain the chafing and rubbing inseparable from the duties of circulation. This, then is an evil born with the coin, and which hastens it to its grave. The "protecting edges," as they are termed, afford no protection to the devices on the coin, but are speedily ground down with them. Thus the allowance made in weight for abrasion is soon disposed of, and the piece becomes "light." In order to obviate this inconvenience, the stamping process of the Mint should be made to administer two blows to each gold coin before it is suffered to leave the dies. One of these would give the impressions, and the other would harden the piece of money, and prepare it for its work. There is no doubt that the second squeeze would add at least a dozen years to the life of a sovereign.

Whether the Mint authorities will entertain this proposition or not is doubtful. Probably they may not appreciate its value, for it has been stated that during the last six months about half-a-million of sovereigns have been annealed at that place after stamping as well as before. If this be true, that half-a-million of coins will not last six months after being issued, that is to say, they will have become light in half a year instead of wearing the eighteen years spoken of by Mr. Jevons. It is scarcely credible that so serious a mistake can have been fallen into, but the parboiled and scratchy appearance of many sovereigns in circulation justifies the belief that it has. Had the Chancellor of the Exchequer taken counsel of practical men as to the best mode of increasing the longevity of our gold currency, and given instructions for renewing our disgraceful silver coinage, he had entitled himself to public gratitude; as it is, he has simply invoked public ridicule or excited the grief of the judicious few.

MANUFACTURE OF CAPS AND CARTRIDGES.

No. IX.

FROM the results of the experimental testing and firing of the completed cartridges, it appears that the *fusil á tabatière* is hardly so much appreciated as it ought to be. It possesses the advantages of being loaded with facility, being readily disembarrassed of the empty cartridge case, and is infinitely simpler in its construction than the more complicated and well-known Chassepot. Having described all the details connected with the manufacture of war cartridges, those belonging to the

other description, intended for the peaceful purposes of sport and the chase, will be now examined into. The general features of both kinds present many points of similarity, and some of absolute identity. Of the numerous varieties of sporting cartridges, those chiefly in use are the vertical and the central-fire examples. The latter description is yet manufactured, but on comparatively a small scale, although it has already partially superseded the original cartridge of Lefaucheux. The component parts of a cartridge fired by a vertical needle are the case, the copper endpiece or socket, the "renfort," the morceau, the chamber, the needle, and the priming. A whole workshop is appropriated to the manufacture of these sporting cartridges, for which there is an enormous demand. In order to effectually solve the problem of their economical and efficient production, M. Gevelot had several conditions to fulfil, which at first sight seemed attended with nearly insurmountable difficulties. One of the first steps to be effected was to render the cartridge air or gastight, so that not a particle of gas should escape at the back end of it when it was fired. Although the escape might not be sufficiently great to cause any injury to the firer, yet the result of the slightest leakage would be to diminish the projectile force due to the expansion of the gas, to reduce the range of the gun, and also to foul the parts in contact with the explosion. The property, therefore, of preventing all escape of gas is an absolutely essential one in the construction of a cartridge. In addition to possessing this indispensable qualification, the cartridge must also be easy of extraction after a shot, and must not undergo too great a dilatation, in consequence of the high temperature to which it is exposed by the ignition of the powder. It must likewise come away in a sound, entire condition, without being torn or mutilated by the discharge, or otherwise the bits that would be detached would interfere with the accuracy of the fire, and necessitate, besides, the frequent cleaning of the weapon. As a last desideratum, their price must be sufficiently moderate to render them suitable to all classes of sportsmen. All these conditions are fulfilled by the cartridges manufactured at present, and they are sold at 15s. 6d. the thousand. To arrive at some estimate of the extent to which the manufacture of sporting cartridges has attained, it may be mentioned that M. Gevelot despatches from his premises every year about 35,000,000, a quantity that will be exceeded next year. Of this number, 12,000,000 are exported—some to Germany, England, and Italy, and others to Spain and Southern America.

There are several varieties of sporting cartridges, but the essential characteristics are common to all. In the first place, a brass endpiece is let into a matrix having a diameter equal to the required bore. The second component piece consists of a solid paper cylinder covered with size, and rolled round a mandril of small diameter. It is in this cylinder that, at the time of the pressure, a punch forms the chamber, where, at a later period of the manufacture, are placed the priming and the two small semi-cylindrical projections, one of which serves as a conductor to the needle, and the other as a support to the priming. A hollow paper tube rolled round a mandril constitutes the third piece. It is subsequently dried and brought to the necessary diameter, and with the brass socket end and cylinder already mentioned completes the cartridge case, which is now ready for striking. The needle is of brass wire cut to the proper length, and its two extremities turned in a different manner. A conically shaped point is given to the end which explodes the priming, while that which is struck by the hammer has a spherical cap-like appearance. The priming consists of fulminate of mercury enclosed in a small brass pan. The cartridges of a better description differ in some respects from the others. The copper ends are deeper, and the paper is of a better quality. Besides, there is a "renfort" or small cylinder of paper or tinsel which virtually doubles the thickness of that portion of the cartridge case, where the pressure from the explosion of the charge is greatest. The priming also is of a better description. We shall now proceed to describe successively the various operations which are executed in the combination of these several parts. The "renfort" is a cylinder of paper or of tinsel, and is prepared by rolling a sheet of either material round a mandril. When it is composed of paper it is coated with paste, and when of tinsel, it is covered with an external cylinder also of paper to prevent it unrolling. In the interior of the "renfort" is enclosed another cylinder of cap paper and paste, termed the "bit." The "bit" is cut out of a roll of paper sheets piled round a core, and between which are placed thick layers of paste. After being dried either in the open air or in a warm current, the rolls and tubes are mechanically cut by small apparatus worked by women. With one hand they push the roll into the interior of a cast-iron cylinder, which has six apertures in it to allow of the passage of a corresponding number of the blades of a circular knife. This knife revolves with great rapidity, and by means of it each woman can cut about 20,000 "bits" per diem. Some of these knives have as many as twenty-five blades. The cartridge case, which is represented to full size in fig. 1, is a hollow

FIG. 1

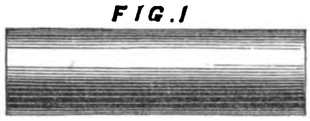

FIG. 2

cylinder cut out of paper tubes rolled round a mandril, and coated not with the ordinary paste, but with a peculiar description made from the skins of rabbits, which are brought to the establishment either in whole skins or in strips. This glue or paste is of an exceedingly adhesive character, and is applied to the paper hot. Upon the tables before the workwomen is placed a copper disc or plate, which serves to roll up the paper on to the proper form and spread the glue on it. So soon as the case is thoroughly dried, the next step is to render it polished and sufficiently smooth to glide easily in the gun. This is accomplished by pushing it over a mandril, and passing it by both extremities successively through a ring, thus bestowing upon it the satin-like appearance so well known in newly made cartridges. The cases are cut to the required dimensions by circular knives, in the same manner as the "bits," which are placed inside the "renforts." In the interior of the "bit," a copper chamber in the form of a cap is fixed by a blow of a lever. The "bit," together with the chamber, is shown in fig. 2. While these operations are in progress at the premises of Moulineux, the brass ends are in process of manufacture at the workshops at Rue Notre Dame des Victoires, where they are stamped and annealed.

THE CONSTRUCTION OF HEAVY ARTILLERY.

THE name of Mr. Lynall Thomas has for long past been associated with the development of the true principles of the science of artillery. Some ten years since, he started his theory of the nature of the action of gunpowder, which he calls the percussive theory. He has now, in a pamphlet* of seventeen pages, developed this theory in a most skilful manner, and has laid down the true basis upon which heavy artillery should be constructed. In order to prepare our minds for the reception of his ideas, Mr. Thomas begins by sketching the theory as laid down by Robins and Hutton, and which was even by them considered faulty. Of course it must be borne in mind that those two students in this field of science laboured principally with a view of ascertaining the effects of a discharge as far as the velocity of the shot and its curved path, &c., were concerned, and the errors of their theory were not brought forth in those startling colours which more recent experiments have imparted to them. They had no such great and costly guns to deal with as we have now; and the bursting of one of their 32-pounders was not so serious a matter to them as similar accidents which are continually depriving us of the substantial results of immense labour and expense are to us. It soon became evident, on the introduction of heavy rifled ordnance, that not only was something wanting to render the rules laid down in the old theory applicable, but that there was some radical and serious error. Large guns which had been constructed at a fabulous cost and were regarded as most perfect specimens of mechanical ingenuity, exhibited such symptoms of premature decline on being tested by charges less than they were intended to carry as to baffle the skill of the most experienced engineers. Some of these destructive engines bulged, and so became unfit for service; others, although preserving their external form, were found after being used for a short time, to have contracted in some mysterious manner a steadily corroding disease, whilst others, again, in a still more alarming fashion, burst into fragments and disappeared with the charge that rent them.

The profession was utterly unable to account for these untoward mishaps. The elder members of the profession, no doubt, congratulated themselves on having been educated in a school in which the construction of such massive pieces was never contemplated, whilst the younger members escaped from the dilemma by asserting that gunpowder was not subject to the control of the laws that regulate the operation of physical or chemical forces. In fact, these irregularities were regarded as nothing more nor less than freaks of nature. It is from this painful state of uncertainty that Mr. Thomas promises to relieve us, and we have every reason to hope, from the suggestions offered in his pamphlet, that his promise will be performed. The word "percussive" conveys to us as much information as names and definitions generally do. In the first place, it is laid down that the whole charge is not inflamed at one and the same instant. This important fact will not be disputed, as it has been already recognized by nearly every writer on the subject. Mr. Thomas then proceeds to assert that that portion of the charge which has been converted into gas impinges with a terrific velocity upon the shot, and begins to expel it before the whole charge is completely consumed, or its force fully developed. This fact, no doubt, induced Mr. Thomas to adopt the phrase "percussive theory," for, as he subsequently says, "the whole time that elapses between the ignition of the charge and the expulsion of the shot from the pieces is scarcely sensible." So far the action of the portion of the charge initially inflamed is of an impulsive or percussive nature, generating, as it does, velocity in the shot in an indefinitely short period of time. After this we arrive at the gist of the whole theory. "Whilst the shot is traversing the initial space the rest of the charge is undergoing complete conversion into gas, and when such conversion has taken place the gas rushes forth in the direction of the axis of the bore." This volume of gas by means of its kinetic energy condenses a portion of itself in that space that has been just vacated by the shot.

Mr. Thomas then proceeds to narrate how he was induced by these considerations to make a series of experiments for the purpose of ascertaining the relation

* The True Basis for the Construction of Heavy Artillery. By LYNALL THOMAS. London: F. TAYLOR and FRANCIS, Red Lion-court, Fleet-street. 1869.

between the initial velocity of the shot, its own weight, and that of the powder employed. Four laws are stated as the results of his observations. By the aid of these laws he deduces expressions for the initial velocity, the tensional strain, and the corroding effect of the pressure. It is then shown how the weights of the powder and shot may be varied according to circumstances without altering the strain on the gun.

It must be confessed that there is something very plausible in this theory; the principles which it embodies are being daily recognised by those who have had experience in gunnery. We hope that our authorities will soon take the important subject into consideration. We shall ourselves hail with delight the establishment of a theory which promises to ensure the safety and perfection of those mighty instruments for the preservation of peace, and to relieve us from the fear of having such gigantic offsprings of labour and ingenuity cut off by any more erratic freaks on the part of nature.

SOMETHING NEW IN PHOTOGRAPHY.

A FEW weeks ago, an announcement was made by Mr. Thomas Sutton, B.A., a scientific gentleman well known to photographers, that he had discovered a new and excessively rapid process of taking negatives. So rapid was it, he stated, that it was too sensitive for use with very quick-acting lenses without stops, and it altogether eclipsed the ordinary wet process. These and other similar announcements were made in his contributions to the "Illustrated Photographer," accompanied by some of the details of the process, and the withholding of some of the essential particulars. The full particulars were to be published in a pamphlet, which pamphlet is now out and lying before us,* we mean, lying on the table before us.

Upon examination of the pamphlet it appears that the process is still a secret one. A special kind of collodion prepared with a special description of pyroxyline is to be used, but the formula for making this collodion is withheld. Those who want it must, according to the pamphlet, go to Mr. Sutton's agents, and buy it at ten shillings per bottle. Had any other man pursued this course, his pamphlet would have been considered as an impudent trade puff by the majority of photographers. In the case of Mr. Sutton, it is a very great error in judgment, and only his long-standing reputation as a skilful scientific photographer, indefatigable in his researches, will save this false step of his from the condemnation a similar line of action would have brought down upon the head of an untried man.

But Mr. Sutton would not commit himself so deeply respecting a new process without it had some merits, so we give the details as far as they have been revealed. In fact, they are all plain enough, with the exception of the kind of collodion used. This collodion contains no soluble iodide, so probably is much the same as the bromised collodion used in Major Russell's tannin process. The coated plate is sensitized in a bath of pure neutral nitrate of silver, strength eighty grains to the ounce of distilled water. Mr. Sutton recommends that the nitrate of silver be also bought of his agent. The time the plate should be left in the nitrate bath is longer than with an iodized collodion; about five minutes would be the time in warm weather, and longer when the temperature is low. It is next immersed for five minutes in a first bath of distilled water, and then placed in a large pan of distilled water, where it may remain some hours, if necessary, until required for use. When that time comes the plate should be washed with a little pure rain or distilled water poured over it from a jug, after which the "organifier" should be applied. Mr. Sutton suggests the substitution of the word "organifier" for "preservative," and in many respects the change is an improvement.

The organifier is composed of:—

Distilled water	1 fluid oz.
Neutral gelatine	3 grains.
Sub-carbonate of soda	3 grains.

The gelatine is dissolved in warm water, then the alkali is added, and the whole filtered through three folds of calico. Nelson's patent gelatine should be used, for acid samples, like most of those of commerce, are worthless, and the sample when dissolved should be tested to see that it does not redden litmus paper. The developer consists of three solutions, which must be mixed and filtered immediately before wanted for use. The solutions are:—

No. 1.	Pyrogallic acid	3 grains.
	Distilled water	1 oz.
No. 2.	Bromide of potassium	20 grains.
	Distilled water	1 pint.
No. 3.	Liq. ammoniæ fortis	1 oz.
	Distilled water	1 pint.

The developer is made by adding twenty minims of No. 2 and twenty minims of No. 3 to one ounce of No. 1.

After the plate is taken out of the camera it should be well rinsed with pure rain water, and the developer applied. The development is slow. In about one minute the details begin to appear, and in from five to ten minutes they are well out, supposing the right time of exposure to have been given. When developed the picture should be well and carefully washed with water from a jug to remove all traces of alkalinity, after which it may be intensified by any of the known methods. Mr. Sutton uses an intensifying solution composed of two grains of pyrogallic acid and thirty minims of acetic acid to the ounce of water, to which is added, just before application to the plate, a few drops of a 30-grain pure nitrate of silver solution. The picture is then again washed, fixed with hyposulphite of soda, and then, after another very thorough washing, is finished and ready for varnishing.

Although no single portion of this process is new, as a whole it is certainly new, for we remember no wet process in which the plates have been alkaline all through the operations. Organifiers are weak developers, or substances having an affinity for oxygen. This tendency to absorb oxygen is increased the more they are rendered alkaline. Gelatine has rather a retarding action upon sensitive films, but, as shown by this process, the addition of an alkali until the verge of fogging is reached increases sensitiveness.

Supposing this process to be only half as sensitive as asserted by Mr. Sutton it is one of very great value, because of the difficulties such a process would remove in the way of obtaining instantaneous views of crowded thoroughfares, and other busy scenes of active life. It is too long and complicated to supplant the wet process in ordinary portraiture. All through the process it is necessary to guard against fogging from diffused white light in the dark room, or from diffused light in the camera or slides. Of course, the greater the sensitiveness the more care must always be taken in this respect.

We trust this process will receive a fair trial at the hands of skilful photographers, though such men do not haste to test every new plan, and Mr. Sutton's mistaken course of so strongly introducing the commercial element is not encouraging. The pamphlet has a neat appearance, and shows considerable taste on the part of its printers, Messrs. Gilbert and Rivington.

* Description of a New Instantaneous Wet Collodion Process. By Thomas Sutton, B.A. London: J. W. Green, 54, Paternoster-row. 1869.

THE TELEGRAPHS' BILL.

ONE of the latest Acts of the past Session was completing the "Telegraphs' Bill," bringing the Government scheme for the purchase of the telegraphs to a successful conclusion by the passing of a Bill authorising the money required for the purchase. The Bill obtained last year was for the purchase of the telegraphs without providing any money, leaving the matter between the Post Office and the various telegraph companies—a question of negociation and arbitration. Provisional agreements were then made, and during the course of the present year indefatigable exertions have been made to settle the amount to be paid to the several companies under their respective agreements. In some cases arbitrations had to be resorted to, and it is owing to the great time occupied by them that the Bill was brought before the House at so late a date as to warrant the fear that it would not become law this Session. It has, however, fortunately passed, slight alterations having been made in select committee, the principal portion of the time being taken up with hearing petitions. The important points in the present Act are the amounts to be paid for the acquisition of the "telegraphs," and the monopoly given to the Post Office.

The preamble recites the objects of the previous and present Acts, which clause 1 enacts may be cited together as the Telegraph Acts, 1868-1869. Clauses 4 and 5 give the monopoly to the Post Office. "The Postmaster-General, by himself or by his deputies, shall from and after the passing of this Act have the exclusive privilege of transmitting telegrams within the United Kingdom of Great Britain and Ireland, and shall also within that kingdom have the exclusive privilege of performing all the incidental services of receiving, collecting, or delivering telegrams." The following descriptions of telegrams are excepted:—Telegrams transmitted by private telegraph for which no charge is made, such as sent by a telegraph maintained and used solely for private use. Telegrams transmitted by a telegraph maintained for the private use of a corporation, company, or persons for which no money or valuable consideration is given. Telegrams transmitted with the written license or consent of the Post Office. Telegrams transmitted by a telegraph company existing on July 22, 1869, the undertaking of which has not been acquired by the Post Office. Transmission of telegrams authorised by the Act of 1868. And telegrams transmitted to or from any place out of the United Kingdom. A penal clause is introduced for contravention of the Act in transmitting telegrams. Powers are also taken for acquiring any undertaking not already agreed to, and a clause is introduced enabling companies to require the Postmaster-General to purchase their undertaking, provided that the Postmaster-General shall not be required to purchase the whole or any part of the undertaking of any company engaged in the transmission of telegrams to or from any place out of the United Kingdom.

In consequence of petitions and efforts made in the select committee the following clause was introduced:—"The Postmaster-General may, upon the reasonable request in writing of any company or person constituted for the transmission of messages to or from any place out of the United Kingdom, make all necessary arrangements for the transmission of such telegrams within the said United Kingdom and for the connection with that view of the cables or other apparatus of the Postmaster-General;" any question arising therefrom to be settled by arbitration, provided that the Postmaster-General may contract with any such company or person or with respect to the construction or use of wires and other telegraphic apparatus in connection with those of the Postmaster-General for the purpose of transmission of such telegrams."

The amount of money authorised to be raised is £7,000,000, and is distributed as follows:—For the purchase of the telegraph companies, £5,715,048; for railway companies, £700,000; and for the other pur-

poses of the Act, £300,000; making in all a sum of less than £7,000,000. The arbitration and agreements with all the railway companies are not yet concluded, so we cannot give the separate amounts, but the actual amount to be paid to the various telegraph companies will be as follows:—

Electric and International Telegraph Company	£2,938,826	9	0
British and Irish Magnetic Company	1,243,536	0	0
Reuter's Telegraph Company	726,009	0	0
United Kingdom Telegraph Company	562,264	9	11
Universal Private Telegraph Company	184,421	10	0
London and Provincial Telegraph Company	60,000	0	0
	£5,715,048	8	11

Such is the large sum to be paid for the undertakings of the various companies. The amount is undoubtedly enormously in excess of the capital expended, and the sum paid for the goodwill must be therefore taken as very considerable; the agreements were on the basis of a twenty years' purchase, at the rate of a certain specified month in last year. If the present Act had not been passed, the various agreements would have lapsed, and in bringing forward the Bill again, the Government would have paid very much more for a bargain that, all things considered, must be looked upon as a favourable transaction.

We are now upon the eve of this important change, the transfer of the telegraphs from private into Government hands, and we cannot but look upon it otherwise than we have always done, as tending to the great benefit of the public at large. A cheap telegraph service, one more extended, opening up fresh districts, extra facilities for telegraphing—all are before us. The one fear we have is that the extra and sudden increase of traffic will at first be too much for the present system, but that we shall fare worse than we do now is manifestly absurd. The entire system as it now is will be bodily transferred; there can therefore be no immediate difference, and there is every hope and probability of things being improved greatly for the better. The actual date of transfer will probably be on the 1st of the new year, preparations having evidently been made for that, as a vote was inserted in the estimates for the amount required for the telegraph service to March, 1870. The question and amount of work involved in the transfer must be very great, and we cannot well see how it can take place at an earlier date than that we have named.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

PROCESS FOR BLEACHING FEATHERS—METHOD OF DYEING LEATHER A LIGHT GREEN—NEW ALLOYS FOR SMALL BELLS—DECOMPOSITIONS EFFECTED BY LIGHT AND HEAT.

THE following is given by Dr. Artus as a perfectly new and very successful process for bleaching feathers, ostrich or goose. The feathers are first to be carefully cleansed from greasy matters, and are then immersed for three or four hours in a dilute solution of bichromate of potash to which a small quantity of nitric acid has been added. In this solution the feathers acquire a greenish colour from the deposition of oxide of chromium, in consequence of the reduction of chromic acid. The nascent oxygen developed in the reduction of course acts as the bleaching agent. To remove the green colour the feathers are afterwards placed in weak sulphurous acid, which dissolves the chrome oxide and leaves the feathers perfectly white. The darkest coloured ostrich feathers are said to be completely bleached by this process, and their value is of course greatly increased. The only precautions to be attended to are not to employ too strong a solution of bichromate of potash, and not to use too much nitric acid. As regards the treatment of goose feathers in this way, it has struck us that, besides being useful as a process for bleaching, it may be an admirable means of disinfecting feathers, and might be applied to the feathers of beds on which people with contagious diseases have lain.

From the same source we have a process for dyeing leather a light green colour. The skins stretched out in the usual way are to be brushed over with a mixture made by dissolving one hundred grammes of iodine aniline green in paste, and ten grammes of picric acid, in five grammes of sulphuric acid and twenty-five litres of water. The shade of colour can be deepened by giving several coverings to the leather. We do not know the aniline green mentioned above, but we suppose it is an article of commerce in Germany.

In the same country there are produced bells of remarkably clear bright tones, which attracted the attention of a chemist and induced him to see what the metal was composed of. He found the metal of a large house bell to be composed of 83·22 of copper and 16·76 of tin. A smaller house bell was composed of copper 83·09, tin 16·80. Another bell was made, copper 84·50 and tin 15·42. These three alloys are said to have a bright white colour like that of silver.

M. Morren, of Marseilles, has followed Dr. Tyndall in experimenting on the action of light on rarefied vapours and gases. Our English Professor, it will be remembered, occupied himself with the vapours of some organic compounds; the Marseilles Professor has experimented with some compound gases, and has found that they undergo a similar decomposition. Thus highly attenuated sulphurous acid exposed in Dr. Tyndall's tube to the electric light gave rise to a cloud of sulphur, which showed that the gas had been completely decomposed, or, as M. Deville would say, the elements were completely dissociated. The experiments of M. Morren show that the chemical rays alone are concerned in bringing about this dissociation, and he sees even in the effects of a heated platinum wire in causing the combination of oxygen and hydrogen, and in its power of decomposing water at the melting point, only the action of the luminous rays emitted.

It is generally believed that sun light is absolutely necessary to enable plants to decompose carbonic acid. M. Prilleux, however, has found that the artificial lights which contain chemical rays—such, for example, as the electric light, and that of burning magnesium—do afford sufficient stimulus to enable a plant to carry on the action, though at a much reduced rate. Thus a branch of potamogeton placed in water containing a little carbonic acid and exposed to sunlight gave off twenty bubbles of oxygen in a given time. Exposed to the electric light it gave off only eleven bubbles in the same time. The evolution of oxygen went on under gaslight, but was very much less.

THE BRITISH ASSOCIATION.

THE business of the thirty-ninth annual congress of the British Association commenced on Wednesday. The first business of the congress was a meeting of the general committee in the school of art in the Albert Memorial Hall, at one o'clock—Dr. Hooker, F.R.S., presiding.

The minutes having been read by the assistant secretary, Mr. Griffiths, and confirmed,

Professor Hirst read the report of the council for the year 1868-9, which was adopted.

The chief officers of the present congress are—

PRESIDENT ELECT—George G. Stokes, M.A., D.C.L., Sec. R.S., Lucasian Professor of Mathematics in the University of Cambridge.

VICE-PRESIDENTS ELECT—The Right Hon. the Earl of Devon, the Right Hon. Sir Stafford H. Northcote, Bart., C.B., M.P., Sir John Bowring, LL.D., F.R.S., William B. Carpenter, M.D., F.R.S., F.L.S., Robert Were Fox, F.R.S., W. H. Fox Talbot, M.A., LL.D., F.R.S., F.L.S.

GENERAL SECRETARIES—T. Archer Hirst, Esq., F.R.S., F.R.A.S., Professor of Mathematics in University College, London; Dr. Thomas Thomson, F.R.S.

ASSISTANT GENERAL SECRETARY—George Griffith, Esq., M.A.

GENERAL TREASURER—William Spottiswoode, Esq., M.A., F.R.S., F.R.G.S.

LOCAL SECRETARIES AT EXETER—Henry S. Ellis, Esq., F.R.A.S., John C. Bowring, Esq., the Rev. R. Kirwan.

LOCAL TREASURER—William Cotton, Esq.

Upon the officers of sections being proposed, Mr. Spence Bate requested that the name of Dr. Percival Wright should be added as a vice-president, which was acceded to at once by the council.

The inaugural meeting was held in the evening in the new drill hall, when Professor Stokes delivered an elaborate and lengthy address, which was repeatedly interrupted by well-merited applause. We regret that our space will only permit of an abstract of the learned Professor's

INAUGURAL ADDRESS.

The President commenced by giving an interesting account of the origin and purpose of the Association, which may be briefly stated to be the giving of a more systematic direction to scientific inquiry, and the organising of means for the prosecution of researches which require co-operation. Apart from the vast amount of time and thought which has been expended on researches through the medium of the society—which latter, at least, cannot be measured by any overt standard—something may be conceived as to what has been done by means of the pecuniary outlay caused by grants for defraying the expenses of such researches, and which up to the year 1867 amounted to £29,288 8s. 1d. When it is remembered that these grants were of small amount, and did not include personal expenses, and that many of the researches involved no money grants at all, some idea may be formed of the amount of scientific inquiry which has been evoked under the auspices of the Association.

Passing to a historical sketch of the most recent progress of science, the President took up the subject of astronomy; and, having traced its progress through Newton, Adams, and Le Verrier, he argued that it might have been supposed, after the brilliant achievements of these discoverers, that the field of astronomical research must have been well-nigh exhausted. But researches which have been carried on within the last few years, even the progress which has been made within the last twelve months, showed how shortsighted such an anticipation would have been, and proof had been given of the value of the union of one science with another, towards which the organisation of this Association had greatly contributed. In an elaborate but untechnical disquisition, admirably adapted to an audience which, whatever infusion of savans it might contain, could not be wholly scientific, Dr. Stokes explained how the sciences of astronomy and optics had acted upon and assisted each other, astronomy being indebted to optics for instruments essential to its development, while astronomy had repaid its debt to optics by an important result, namely, the first proof of the finite velocity of light, and the first numerical determination of that enormous velocity. By means of optics, and especially by means of the spectroscope, the motion and the masses of the heavenly bodies had been more fully revealed to astronomical observation. In some detail, the theory of "fixed stars" was next dwelt on, the result being laid down that the term was not wholly exact, inasmuch as it was proved that the stars, including the first and greatest of stars—the sun—or some of them at least, are moving in various directions in space, and that it is merely the transversal component of the whole motion, or rather of the motion relating to our sun, that is revealed to us by a change in a star's apparent place. In regard to determining whether any particular star is approaching or receding from the sun, astronomy alone was powerless to help researches; and here the science of optics came in in a remarkable manner. By an analogy, almost fanciful, but specially illustrative, between the sound of a bell and the vibratory movement of light, it was shown that, by means of optical science, evidence had been obtained that light consists of a tremor or vibratory movement, propagated in an elastic medium, filling the planetary and stellar spaces—a medium which thus fulfils for light an office similar to that of air for sound. Here opportunity was taken to illustrate the theory propounded by references to the researches in regard to the solar spectrum of Professor Kirchhoff, and the result of observations obtained by the use of a telescope furnished with a spectroscope of high dispersive power by Mr. Huggins, in the solar system, and which presented a grand conception of the unity of plan pervading the universe.

The President then turned to a recent application of spectral analysis, in the observation of the total eclipse of the sun, August 17, 1868; the use of which was carried out on that occasion by two expeditions from England, to the countries crossed by the line of central shadow, under the auspices of Captain Herschel and Major Tennent. The information received had proved to be most valuable, or, as Dr. Stokes phrased it, "most precious;" and was a special illustration of the reacting on

each other of astronomy and optics. This theme was still further worked out elaborately; and, in apologizing for dwelling upon it so long, the President adduced it as evidence of the value of the object of the Institution—that of a union or bringing together of the different branches of science. He congratulated the Association on having attained an object for which it has been labouring ever since 1849, namely, the establishment of adequate instruments for astronomical observations in the southern heavens, which had at last been achieved by the erection of a telescope at Melbourne, Australia, for which a grant of £5,000 had been made by the Colonial Legislature, and which is now under the superintendence of Mr. Le Sueur. A very interesting account was next given of the issue of an inquiry by a Royal Commission, appointed at the instance and by the pressure of the Association, into the application of gun-cotton to warlike purposes. It had been shown that there are some purposes for which gun-cotton can advantageously replace gunpowder, while its manufacture and storage can be effected with comparative safety. It had been spoken of highly, though only promisingly, for the use of small arms; though, even in the state of development to which it has attained, its application to great guns seems more doubtful. Next it was stated that, owing to the exertions of the Royal Society, soundings in great ocean depths had been undertaken by the Admiralty, and dredging had been carried down to more than 2,400 fathoms, and animal life had been found in that depth in considerable variety; while, in a depth of 650 fathoms, the existence was established of a varied and abundant fauna, at depths which had been supposed to be either azoic or occupied by animals of a very low type; besides which the character of the fauna and the mud brought up was such as to point to a chalk formation actually going on.

Diverging to an interesting personal topic, the President told them it was found impossible to make the Chancellor of the Exchequer understand that any contribution should be made out of the taxes paid by the people towards a memorial to a man like Faraday; and how happily that object would be carried out by the voluntary exertions of those who appreciated his individual and scientific merits. In regard to chemistry, it was stated that no great step had been made; but an account was given of the discovery of the existence of a red colouring matter obtainable from the wings of the turaco, or Plantain-eater, of the Cape of Good Hope, a bird celebrated for its beautiful plumage; and another of the improvement of alizarine, one of the components of madder, which occupies so important a position amongst dye-stuffs of calicoes. Again, it was stated that by the action of hydrochloric acid on morphia a new base was produced, whereby the narcotic properties of morphia were changed, so that it became a powerful emetic, unattended by injurious after-effects. In relation to mechanism, a graceful allusion was made to this being the centenary of the great invention, the steam-engine.

The last subject comprised in the address was the branches of science more or less concerned with the phenomena of life, in which the bearing of physical on biological science was dwelt upon. This was argued out with great minuteness and ingenuity, and concluded as follows:—But do the laws of chemical affinity, to which, as I have endeavoured to infer, living beings, whether vegetable or animal, are in absolute subjection, together with those of capillary attraction, of diffusion, and so forth, account for the formation of an organic structure, as distinguished from the elaboration of the chemical substances of which it is composed? No more, it seems to me, than the laws of motion account for the union of oxygen and hydrogen to form water, though the ponderable matter so uniting is subject to the laws of motion during the act of union just as well as before and after. In the various processes of crystallisation, of precipitation, and so forth, which we witness in dead matter, I cannot see the faintest shadow of an approach to the formation of an organic structure, still less to the wonderful series of changes which are concerned in the growth and perpetuation of even the lowliest plant. Admitting to the full as highly probable, though not completely demonstrated, the applicability to living beings of the laws which have been ascertained with reference to dead matter, I feel constrained at the same time to admit the existence of a mysterious something lying beyond—a something *sui generis*, which I regard not as balancing and suspending the ordinary physical laws, but as working with them and through them to the attainment of a designed end.

What this something which we call life may be is a profound mystery. We know not how many links in the chain of secondary causation may yet remain behind; we know not how few. It would be presumptuous indeed to assume in any case that we had already reached the last link, and to charge with irreverence a fellow worker who attempted to push his investigations yet one step further back. On the other hand, if a thick darkness enshrouds all beyond, we have no right to assume it to be impossible that we should have reached even the last link of the chain—a stage where further progress is unattainable—and we can only refer the highest law at which we stopped to the fiat of an Almighty Power. To assume the contrary as a matter of necessity is practically to remove the first cause of all to an infinite distance from us. The boundary, however, between what is clearly known and what is veiled in impenetrable darkness is not ordinarily thus sharply defined. Between the two there lies a misty region, in which loom the ill-discerned forms of links of the chain which are yet beyond us. But the general principle is not affected thereby. Let us fearlessly trace the dependence of link on link, as far as it may be given us to trace it, but let us take heed that in thus studying second causes we forget not the first cause, nor shut our eyes to the wonderful proofs of design which, in the study of organized beings especially, meet us at every turn.

Truth we know must be self-consistent, nor can one truth contradict another, even though the two may have been arrived at by totally different processes—in the one case, suppose, obtained by sound scientific investigation; in the other case, taken on trust from duly authenticated witnesses. Misinterpretations, of course, there may be on the one side or the other, causing apparent contradictions. Every mathematician knows that in his private work he will occasionally, by two different trains of reasoning, arrive at discordant conclusions. He is at once aware that there must be a slip somewhere, and sets himself to detect and correct it. When conclusions rest on probable evidence, the reconciling of apparent contradictions is not so simple and certain. It requires the exercise of a calm, unbiassed judgment, of looking at both sides of the question; and oftentimes we have long to suspend our decision, and seek for further evidence. None need fear the effect of scientific inquiry carried on in an honest, truth-loving, humble spirit, which makes us no less ready frankly to avow our ignorance of what we cannot explain than to accept conclusions based on sound evidence. The slow but sure path of induction is open to us. Let us frame hypotheses if we will; most useful are they when kept in their proper place, as stimulating inquiry. Let us seek to confront them with observation and experiment, thereby confirming or upsetting them as the result may prove; but let us beware of placing them prematurely in the rank of ascertained truths, and building further conclusions on them as if they were.

When, from the phenomena of life, we pass on to those of mind, we enter a region still more profoundly mysterious. We can readily imagine that we may here be dealing with phenomena altogether transcending those of mere life, in some such way as those of life transcend, as I have endeavoured to infer, those of chemistry and molecular attractions, or as the laws of chemical affinity in their turn transcend those of mere mechanics. Science can be expected to do but little to aid us here, since the instrument of research is itself the object of investigation. It can but enlighten us as to the depth of our ignorance, and lead us to look to a higher aid for that which most nearly concerns our well-being.

At the conclusion of the address, a vote of thanks was moved to the President by the Earl of Devon, seconded by Sir Stafford Northcote, and carried amidst great applause.

TREATING CORN FOR PANIFICATION.

An improved mode of preparing corn for the manufacture of bread without the process of grinding, whereby all nutritious portions of the grain are retained, and only the outer pellicle removed, has been patented in England by M. Alexandre Sezille, of 10, Rue de Lancry, Paris. Corn contains only from 4 to 5 per cent. of indigestible pellicle; when this has been removed, all the remaining parts constitute a nutritious aliment when mixed together; the practical application of this principle forms the basis of this invention. The existing system for transforming corn into bread by reducing it first into flour has only rendered about 80 per cent. of the grain available for this purpose, which 80 per cent. under favourable circumstances, give about 112lb of bread to 100lb. of grain. By the present improved process, from 145lb. to 150lb. of bread are obtained from 100lb. of grain, giving an increase of about 33 per cent. over the ordinary process. At the same time, the improved process, in doing away with the grinding, preserves a much greater quantity of gluten which, in the ordinary system, is lost by decomposition through heating during the grinding; also, the improved mode of fermenting the dough does not attack the gluten so much and renders it of a much whiter colour. The bread is therefore not only of greatly increased yield, but it is also more nourishing. The improved process consists of the following operations:—First operation.—The grain is thrown into a receptacle filled with water, and is stirred about therein for some minutes, when any defective grain will float on the top of the water and can readily be removed. The washing has also for its object to remove dust and other impurities. After the grain has been steeped in the water for about half-an-hour, the water (which will be found quite turbid even with the best grain) is run off. In place of steeping the grain, it may also be merely subjected to the action of jets of water. By this first operation the pellicle of the grain is distended.

Second operation.—The grain thus moistened is passed through a sheet metal cylinder or tube having a rasp-like inner surface, whereby the outer coarser pellicle of the grain is removed. The second pellicle beneath, which is the colouring matter, is removed by passing through a horizontal sheet metal cylinder with rasp-like inner surface, inside which are moving stiff brushes which act on the grain and render it as white as rice. The pellicles may, however, be removed by any apparatus suitable for the purpose.

Third operation.—This operation consists in steeping the grain after removal of the pellicle in a vessel filled with fermenting liquor, prepared, as we shall presently describe, at a temperature of from 68deg. to 77deg. Fah., and in the proportion of about 200lb. of liquor to about 100lb. of grain, in order that the latter may be well covered with the water. The grain is introduced after the liquor has been prepared about from eighteen to twenty-four hours, in order that this may have attained its full energy. The grain is subject to the action of the liquor for about seven or eight hours, during which time the fermentable matter in the liquor acts by degrees on the grain, penetrating into it gradually and extracting to a great extent the colouring matter situated beneath the skin of the grain; the liquor, which becomes of a reddish tinge, is then drawn off. The fermenting liquor is prepared by mixing with water, at a temperature of from 68deg. to 77deg. Fah., about 10 per cent. of fermented dough.

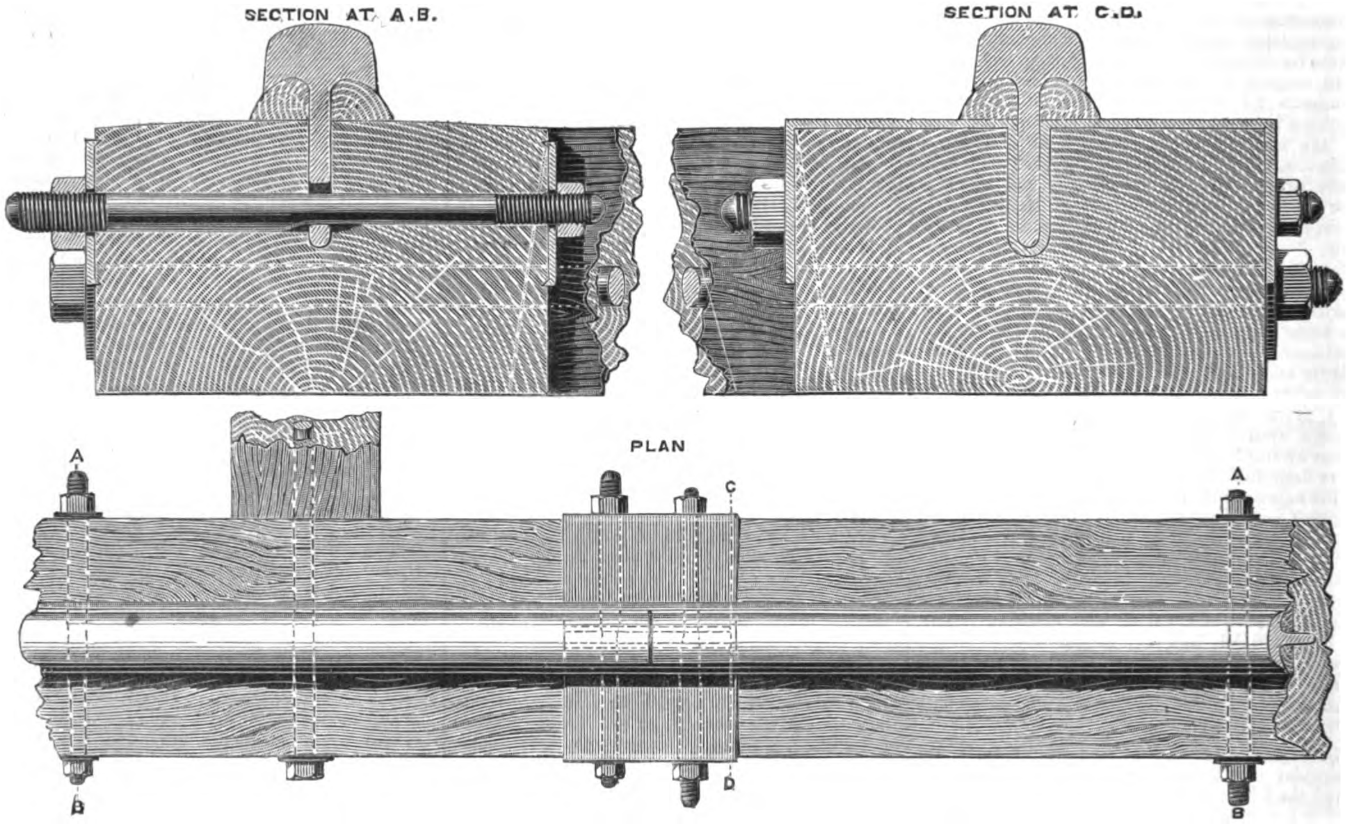
Fourth operation.—The grain is then drained, and is placed in a hopper, which, by means of a distributor, causes it to pass between one or more pairs of revolving cylinders which reduce it to paste as it passes through; this being completed, the requisite quantity of salt is dissolved in water and is then poured on the dough placed in a kneading trough. The dough is then kneaded so as to thoroughly mix all the particles thereof, and the operation of making bread is completed in the usual manner, that is, the dough is divided into loaves, turned, left for completion of the fermentation, and, at the desired moment, is placed into the oven, yielding a very white and nourishing bread.

The sediment remaining at the bottom of the steeping vessel in the third operation can, after drawing off the coloured water, be mixed with the paste passing from the crushing cylinders in the fourth operation. For making biscuits by this process the grain is not allowed to soak for so long a time as for bread, and, in order to produce a paste of greater consistency, it is passed twice through the cylinders; it is then treated in the ordinary manner. It is preferred to pass the dough through machines similar to those employed for moulding earthenware drain pipes in a continuous manner, and through dies imparting to the biscuit the desired width and thickness; the dough, in passing through the dies, will also attain a more homogeneous condition.

This improved system of preparing corn for bread has the further advantage of requiring considerably less motive power than the existing system, in addition to which the machinery, apparatus, and implements are of a much simpler character, and the different operations can be effectually carried on without the employment of specially skilled workmen.

LONGITUDINAL TIMBER PERMANENT WAY.

BY MR. G. F. GRIFFIN.



GRIFFIN'S LONGITUDINAL PERMANENT WAY.

THE permanent way of railways is a question which has engaged the attention of engineers and inventors ever since the first rail of the first railway was laid. Judging from what has already been done, and from the enormous number of patents which have been taken out upon the subject, we thought it hardly possible that any novelty could be produced in this direction. But Mr. G. F. Griffin—whose name has for some years past been connected with the permanent way question—has shown us something new in his longitudinal timber system, which we recently inspected at his offices, 19, Great George-street, Westminster. This system is illustrated in the accompanying engraving in section and plan. It will be seen to consist of a longitudinal sleeper, in which a groove is cut to receive the rail, which is of the single-head type, having a vertical web and weighing but 60lb. to the yard. The rail is packed under the head with oak packing strips, and is held in place by through bolts of varying diameters, as shown in the section taken through A B. This form ensures that the inclined shoulder of the bolt shall bear against the lower side of the hole in the rail-web, thus forcibly drawing down the rail upon the packings and sleeper. A wrought-iron strap plate is used at the joints, as shown in the section through C D, which binds the parts firmly together, the bolts being placed with the small and large ends alternating. The transoms are placed at the usual intervals and are fixed by through bolts, as seen in the plan. This system offers many advantages, especially over the transverse sleeper system generally adopted. It is about as simple a way as could be laid, and at the same time it attains to a maximum of safety. Its great economy over the transverse system lies in the absence of chairs, keys, trenails, and spikes, which are entirely superseded. Then there is a further saving in the first cost of rails, a much lighter rail being used by Mr. Griffin, and for which the system is particularly adapted. The maintenance of way—the *bete noir* of permanent way engineers—is stated to be reduced to one-half of what it is at present. Happy for the line that adopts his system if this be so, and we see no reason to question such a result, as bolts and nuts are very different things from wooden keys and trenails to deal with. The keys are perpetually playing fast and loose as the weather is either damp or dry, and the trenails are constantly getting sheared. The actual economy in maintenance of the new system, however, is a point which the experience of practical working alone can decide. This we believe it will shortly have, as we are informed that it will soon be laid on two of our leading railways. Unquestionably the longitudinal is the best system for rapid and safe travelling. Brunel was well aware of this when he laid the Great Western way, and the happy combination which Mr. Griffin has effected promises to supersede the chattering arrangements now so generally in vogue.

LECTURE EXPERIMENTS TO ILLUSTRATE THE LAWS OF MOTION.*

BY PROFESSOR ROBERT BALL, A.M.

I HAVE found the arrangements described in this paper effective in demonstrating to an audience a few elementary properties of gravitation and the laws of motion. It is certainly true that a clear appreciation of the truth of these laws, so essential for properly studying dynamics, requires some experimental illustration to beginners. However satisfactory may be the multitudes of indirect proofs of these laws with which the more advanced student is familiar, it will hardly be denied that it is a little difficult to demonstrate them directly. So far are they from being axiomatic that for centuries they were not believed at all.

The apparatus which is described in works on physics as available for the purpose of proving them consists merely of a very few instruments, among which Atwood's machine is that most commonly referred to. This meagreness contrasts strangely with the profusion of apparatus which has been devised for the illustration of the elements of other branches of science (electricity, for example); yet surely it would be as desirable to prove to a student the second law of motion by direct experiment, as it is to demonstrate experimentally the laws of electrical induction. I have communicated this paper, thinking that any contribution, however small, to the list of apparatus available for this purpose might prove useful to others, as it has been to myself.

A certain principle should always be borne in mind by the arranger of an experiment which is to be used for purposes of elementary instruction. A law A is required to be proved, and an experiment is performed which demonstrates the fact B; it is then shown by logical inference that the truth of the fact B necessitates the truth of the fact A. Thus A has been proved by two distinct steps—first, the experiment proving B; second, the chain of reasoning connecting A with B. For the instruction of a class of beginners it is essential that the experiment be so selected that the second step be reduced to a minimum, or, if possible, totally dispensed with. To take an illustration from the subject with which we are engaged. Suppose it be required to prove that a body will fall 16ft. in the first second. The distance may, of course, be determined most accurately by finding the time of vibration of a pendulum; but the subsequent chain of reasoning would be quite unintelligible. Atwood's machine might be made to give some approximation to the value; but it likewise does not indicate the direct result, but rather something from which the direct result is to be inferred by calculation. This appears to me one of the defects in Atwood's very beautiful machine; it possesses neither great accuracy nor great simplicity in the interpretation of its results, and one or the other, if not both, of these features should characterize every experiment. Besides, in its ordinary form, Atwood's machine is quite unadapted for use in the lecture theatre.

The arrangements now to be described have been designed with a view of proving the points required as directly as possible, and with the minimum amount of subsequent reasoning. It should be mentioned that whatever has been necessary for the purpose of supports and framework has been constructed out of the very beautiful system devised by Professor Willis, and described in his "System of Apparatus for the Use of Lecturers and Experimenters in Mechanical Philosophy." The convenience of this apparatus for every kind of mechanical appliance in a lecture room is wonderful. All bodies fall through the same height in the same time. This was Galileo's experiment from the top of the tower of Pisa; it can be repeated on a small scale in the lecture room in a striking manner. A scaffolding is built up with the stool, beds, and bolts of the system; and thus at the height of 24ft. from the floor a pulley is supported, through which passes a rope. A piece of wood, the shape of an equilateral triangle, 9in. each side, has two electro-magnets, each 3in. long, attached to its base, the wire being continuous round the two magnets. The triangle is attached by its vertex to the rope, and can therefore be easily raised to 24ft. or any less height, and lowered again at pleasure. The two wires communicating with the electro-magnets are sufficiently long to allow of the triangle and mag-

* Communicated by the author to the "Philosophical Magazine."

nets being hoisted up while the other ends of the wires are attached to a battery of a few cells, a contact-breaker being introduced into the circuit.

The mode of experimenting will be easily understood. Suppose it is desired to prove that a heavy iron ball and a light one will fall through the same height in the same time. The circuit being complete, the balls are attached one to each of the electro-magnets, care having been taken to interpose a piece of paper between each of the balls and the corresponding magnet, as this ensure their being disengaged simultaneously. The piece of wood and its freight are then hoisted up 24ft. (or less), and the two balls are in the same horizontal line, supported, of course, merely by the attraction of the magnets. At a signal, the current is broken and the balls fall together; they are disengaged simultaneously; and the line joining them is easily seen to be horizontal throughout their entire descent, though, of course, they are perfectly free from each other. The iron balls used were 1in. and 1½in. in diameter respectively.

An iron ball (1½in.) and a cork ball (2½in.) can be likewise tried. A flat headed nail driven into the cork affords sufficient holding-ground for the magnet. It is a most unexpected result to find that when they reach the ground, or rather the cushion placed to receive them, the cork ball is only a few inches behind its weighty companion. That even this difference is due to the resistance of the air is shown in the next experiment, by lowering down the triangle, again affixing the cork ball, and likewise the iron ball, with a small parachute of cardboard attached to it. Raising up the triangle and again breaking the current, the cork is seen this time to reach the ground before the iron.

The next experiment is to prove that a body falls 16ft. in the first second. The apparatus already described is employed for this purpose, but into the same circuit two other parts are introduced which will require a few words of explanation. The contrivance on which the arrangement principally depends is the contact-breaker, the action of which will be understood from the annexed diagram (fig. 1). To a block of wood

FIG. 1.

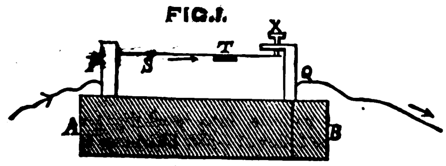


FIG. 2.

A B a brass pillar P is screwed. This pillar is 3in. high, and has a binding-screw attached to it to receive the current. Near the top of the pillar a very slender spring is riveted; this spring is of brass wire slightly flattened, and is 8in. long; at the point T, 5in. from P, it bears what may be called a saddle. This consists of a piece of ordinary tinplate cut into a rectangle of 1in. by ¼in. soldered lengthways on the upper surface of the spring and then bent down on each side, so that its section is similar to what is represented in fig. 2. The object of this will presently appear. The other end of the spring is free, but it bears against a screw X, which turns in a brass piece Q, likewise screwed to the block of wood A B. The spring being weak enough, the slightest touch will depress the end of it from X, to which, however, it immediately returns on the relaxation of the pressure. When the spring (along which the current travels) touches X the circuit is complete, and it is of course interrupted when the spring is depressed.

A seconds-pendulum is suspended from a suitable portion of the framework by a spring in the usual manner. No clock-escapement is used; indeed, if the bob be heavy, the pendulum once set in motion will vibrate for some minutes without requiring an additional impulse. Underneath the pendulum the contact-breaker is to be placed in such a manner that its spring is normal to the plane of vibration of the pendulum; and the height of the pendulum must be so adjusted that when the bob is in its lowest position, a point attached to it shall just touch the saddle in passing over it. The final adjustment, however, is inconvenient to make by moving the point of suspension of the heavy pendulum; so for the sake of making this with the necessary delicacy, the screw X has been introduced into the contact-breaker, by raising or lowering which the limiting position of the spring and therefore of the saddle is raised or lowered. By this means the amount by which the pendulum depresses the spring in its transit over it can be arranged with the greatest nicety. After the pendulum has received an impulse, and as the bottom of its swing comes into contact with the saddle, the current is broken owing to the depression of the spring from X. After the point has passed the saddle, the spring returns to its bearings, and the current flows again until the return of the pendulum to the lowest point, when the current is broken again; and if the contact-breaker have been nicely adjusted, exactly a second will have elapsed between these two breakings. Thus at the completion of each second the current is interrupted. The apparatus being nicely adjusted, the amount of *vis viva* lost by the pendulum in depressing the spring is so small that it will make, after having received an impulse, upwards of 200 breakings before it requires another push.

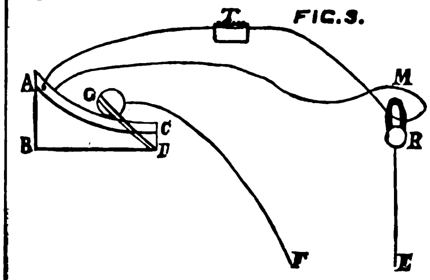
An electro-magnet acting on a bell is introduced into the circuit, so arranged that at each interruption of the current the bell is struck. The simple arrangement necessary for this need not be described. At every oscillation of the pendulum the bell rings, the sounds of which may therefore be regarded as the ticks of the pendulum rendered easily audible to the whole room. The reason why the spring or middle of the saddle of the contact-breaker should be placed exactly under the point of suspension of the pendulum can now be easily seen. It is in order that the intervals of two consecutive strokes of the bell shall be exactly equal. If the spring have not the correct position, then there will be two intervals, one as much greater as the other is less than a second, and these intervals will alternate. Errors which arise from the want of perfect adjustment of this position are fortunately rendered insensible by the fact that at its lowest point the pendulum has its maximum velocity. It will be noticed that with this contact-breaker the interval between the strokes is independent of the arc of vibration. I am not aware that this mode of breaking contact has been used before, and therefore I have given the details. It appears convenient, efficient, accurate, and not liable to derangement, and is free from the troubles (in my experience unavoidable) arising from using mercury or other fluids for the same purpose.

The mode of proving that a body falls 16ft. in a second is then easily seen. A large scale divided into feet is attached to the upright support of the pulley. One or both of the electro-magnets belonging to the triangle, the contact-breaker, and the bell are all included in a battery of a few cells. The pendulum being held to one side (for in its position of rest the point keeping down the saddle breaks the current), the current passes. An iron ball is attached to the electro-magnet, which is then hoisted to the height of 16ft. (as pointed out by the scale) above the surface of a cushion on which the ball is to fall, so as to deaden the sound. The eyes of the audience are to be directed to the cushion, while their ears listen for the bell. When the pendulum is released, the first break rings the bell and drops the ball together; the second break rings the bell again, and, as nearly as the eye and ear can judge of simultaneity, identically at the same moment as the ball reaches the cushion. If the ball be hoisted to the height of 18ft., it is seen to be too late; if lowered to 14ft. it is seen to be too soon. From this may be inferred the amount of accuracy of which the experiment is capable. It must be remembered that the arrangement is one for illustrating a certain quantitative result to an audience, and not for determining in the cabinet an important natural constant.

The next experiment may perhaps claim greater accuracy than that just described, as there is always more or less of difficulty (more, apparently, with some persons than others) in perceiving the identity of time of two phenomena presented to two different senses simultaneously. This arrangement depends only on the sense of sight; and the law which it demonstrates may be thus enunciated. "A body projected in a horizontal direction with any velocity whatever will take the same time to reach the ground as a body let fall vertically through the same height." This clearly is an important truth to impress on a beginner endeavouring to understand the second law of motion. It will teach him that, in at all events one very important case, the effect of the same force acting for the same time does not in the least depend upon the circumstance as to whether the body on which it acts is at rest or in motion; and perhaps this is the least self-evident of the truths that are wrapped up in Newton's concise enunciation of his law.

The arrangement consists of two parts, and the assistance of electricity as a rapid messenger is again called in. A B C D (fig. 3) is a piece of wood 1½in. thick; A C is an arc of a circle of 2ft. radius, the tangent to which at C is horizontal, A C being about a foot long. A ball being intended to run down this piece, it is grooved; and A C is one of the edges of the groove, the other being of course at a distance of 1½in. on the other side of the wood. The ball which rolls down the groove is a sphere of 2½in. in diameter, made of wood and neatly covered over with tinfoil. The two edges of the groove are each likewise covered with a piece of tinfoil, which pieces, however, must at no place communicate with one another. Each edge is furnished with a binding-screw, to which

FIG. 3.

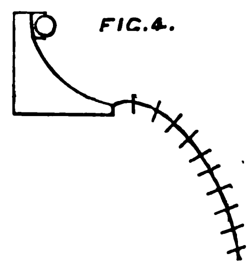


a wire is attached. Whenever the ball rests on the groove, the tinfoil enclosing it touching each edge completes the electric connection between the two binding screws, the ball acting as a bridge along which the current passes. At D, and the similar point on the other side, the two ends of a piece of india-rubber spring are fastened so that the ball can be grasped by the spring. When the ball is pulled up along the groove and then released, the force of the spring pulls it down and it darts off with a horizontal velocity. This piece of apparatus may be about 7ft. from the ground. At precisely the same vertical height as C, and at a distance of some feet, an electro-magnet M is to be supported. One wire from this goes to the battery, the other is fastened to one of the binding-screws on one edge of A C, the second edge being connected with the other pole of the battery.

As long as the tinned ball P is on the groove, the circuit being complete, the electro-magnet M will sustain a second ball R; but the moment P leaves the groove, R is released. Drawing back P and the spring which embraces it and then releasing it, P maintains the circuit until it arrives at C; in fact, a good contact is ensured by the double circumstance that both the spring and the centrifugal force of P conspire to keep it in close contact with the tinned edges. After leaving C the ball darts off in the trajectory indicated in the figure; but directly it is free R is likewise free, and the two can be seen with the greatest exactness to reach the ground together. By stretching the spring more or less, any amount (within reasonable limits) of horizontal velocity can be communicated to P; and it is a most striking result to observe in all cases the perfect simultaneity with which the two balls reach the ground. For demonstrating the particular point in question, this arrangement apparently leaves little to be desired.

"The path of a projectile is a parabola." The method of demonstrating this is indicated in M. Daguin's "Traité de Physique" (vol. i. p. 94). The arrangement for the lecture-room based upon it is simple enough. A quadrant (fig. 4) of 2ft.

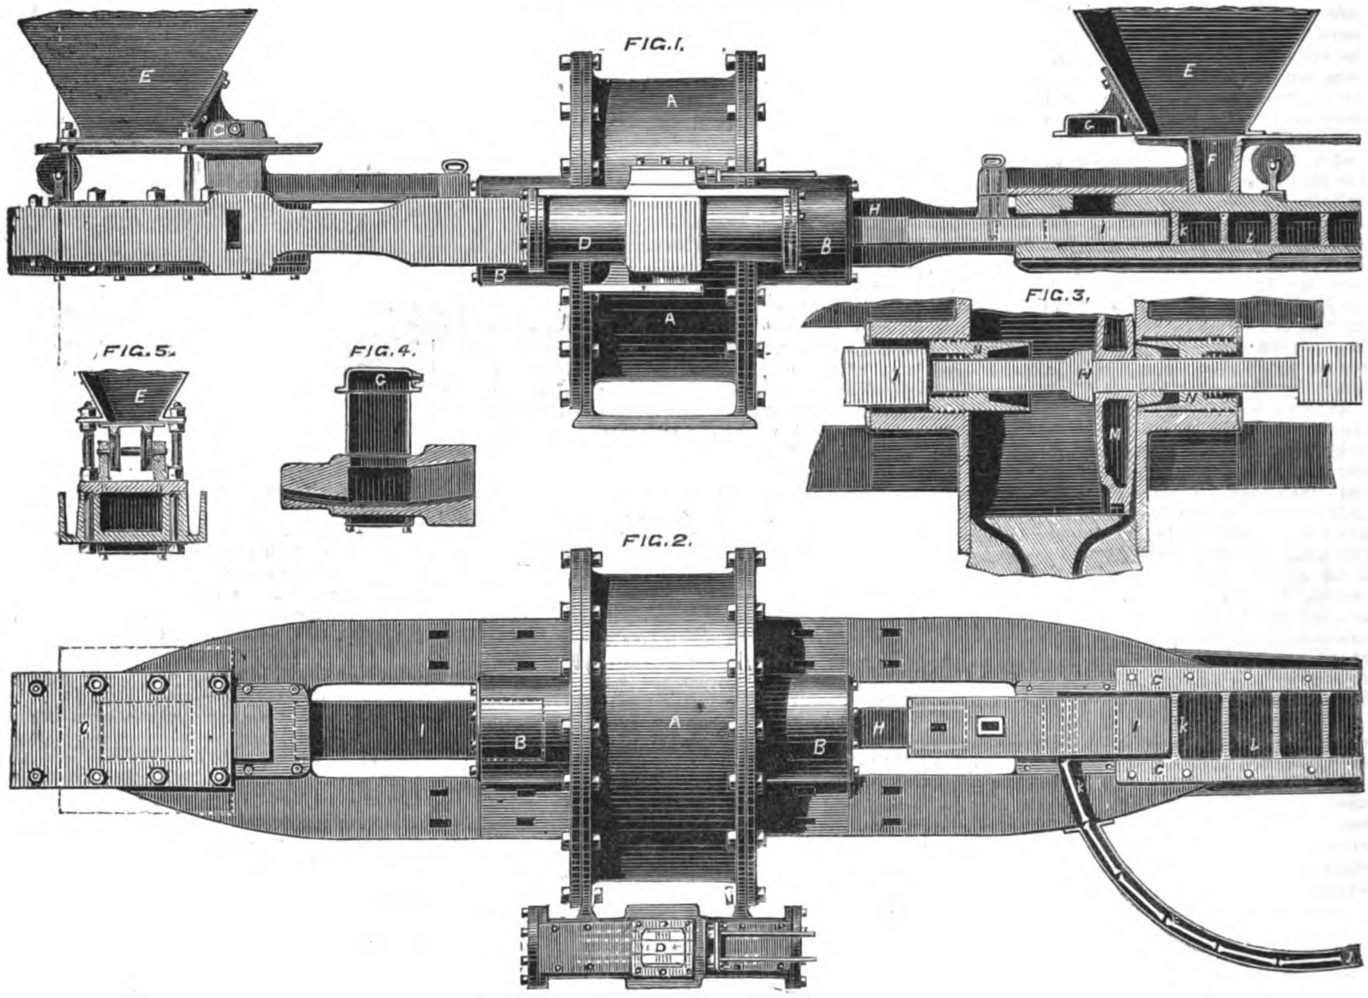
FIG. 4.



radius is made of wood 1½in. thick, and grooved as in the preceding experiment. This is to be very firmly supported parallel to the wall and about 2in. distant from it, and 6ft. or 7ft. from the ground. Down this a wooden ball 2½in. is to roll, and it is proposed to prove that the path it follows after leaving the groove is a parabola. That the ball after rolling down shall describe precisely the same path each time, it is necessary that the direction of projection be perfectly constant; this is ensured by fixing the quadrant very firmly; and then the direction of projection is the tangent at

MACHINERY FOR COMPRESSING COAL.

BY MR. H. G. FAIRBURN.



he base, which for convenience is horizontal, or nearly so. It is no less necessary that the velocity of projection be constant; this is provided for by allowing the ball always to start from the same position on the quadrant. To secure this, a small ledge is fastened at the top, and the ball is, before each descent, brought home against the ledge, and thence allowed to fall. By this means, the same trajectory can be reproduced as often as desired.

To show that this is a parabola, the following simple plan is employed. A number of little arches are made from slips of cardboard 1in. wide; these arches are about 4in. across and 6in. high, something like the shape of the letter U turned upside down. They are fastened to the wall by drawing-pins or otherwise all along the constant path traversed by the ball, as shown in the figure. The mode of placing them is easy. First, one is arranged so that after each descent the ball goes through its centre; then the next is similarly placed, and so on until ten or thereabouts have been affixed, through all of which, and without touching any, the ball will pass, after leaving the curve, finally falling into a basket placed to catch it. By joining the centres of the arches along the wall by a curve, the position of the focus and directrix of the parabola will be easily found, and the nature of the trajectory consequently demonstrated.

COMPRESSING COAL.

MR. H. G. FAIRBURN, of 45, Goswell-road, London, has recently patented some improvements in his machines for compressing coal. These improvements are of three kinds, and they apply, firstly, to the construction of the cylinder portion of the machinery, the objects being to economize the consumption of steam and to prevent breakage or injury to the dies or palletts. Secondly, to the arrangement for introducing the dies or palletts into working position. And, lastly, they include an arrangement whereby for pressing coal and other substances that require the palletts to be cool, they may, after having been in contact with the heated material, be cooled before being introduced into the machine, while for pressing peat and other substances that require the palletts to be hot, they can be introduced into working position in a highly heated state.

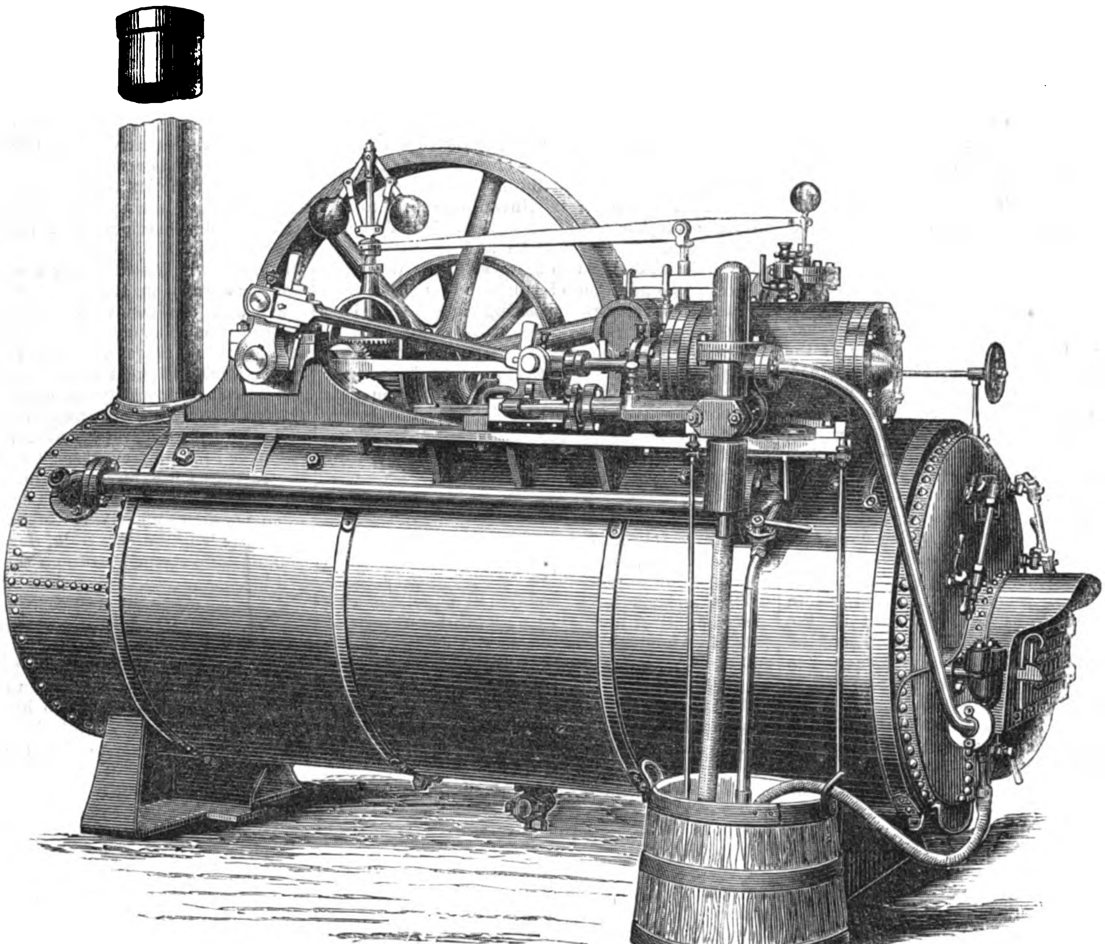
The first part of this invention is accomplished as follows:—Mr. Fairburn bores out the centre of the cylinder caps at both ends of the cylinder and forms in continuation a small cylinder at each end of the large cylinder, into each of which is inserted a movable adjusting plug. These plugs are capable of moving forward into the large cylinder, but cannot move backward or out farther than will bring their inner surfaces flush with the inner surfaces of the ends of the large cylinder. The piston being in the centre of its stroke, and the piston rod passing right through the large cylinder and out at each end, and through each of the adjusting plugs, stops are placed on the piston rod, one just at the outer edge of each of the adjusting plugs, so that the piston cannot move in either direction without drawing one of the plugs into the interior of the large cylinder. If now the piston be passed to one end of the large cylinder it will have drawn with it, by reason of the stop on the piston rod, one of the plugs as far into the cylinder as can be drawn, while the stop on the piston rod at the outside of the other plug will have left that plug by the same distance as the first plug is projecting within the large cylinder. The steam slide valve which has let the steam into the cylinder to bring the piston up to one end now opens a communication between the two ends of the cylinder, thus producing an equal pressure of steam on each side of the piston, but as on one side the steam acts on the movable plug drawn into the cylinder by the piston rod, the tendency of the plug to regain its position acts on the piston and forces it back until the stop on the piston rod on the outside of the other plug comes into contact with that plug when the piston remains stationary, at the same time closing the communication between the two ends of the cylinder; communication between one end of the cylinder and the exhaust is now opened in the usual manner, and the steam being let in on the other side of the piston it is driven home with the full pressure of the steam.

The second part of the invention, namely, the placing of the palletts into working position, is accomplished as follows:—Mr. Fairburn employs a flat circular ring in a horizontal or oblique position, of such a diameter that while one extremity of its circumference is in a position to introduce the palletts into the moulding chamber or pressing tube, the opposite portion of the circumference of the ring just passes beyond the end of the pressing tube to receive the palletts expelled therefrom after they have passed through the tube between the blocks of pressed material. Around this ring on its flat surface the palletts are laid, and are carried to their position by their own gravity, or a step-by-step motion being given to the ring the palletts are brought one after the other into the mouth of the moulding chamber, to be forced therein by the plunger or piston rod, as already described. Or, instead of the said ring, there may be an endless chain or belt worked in a similar manner, and each link carrying a horizontal platform to receive a die or pallett. In this manner the palletts may be heated or cooled in their transit by any ordinary process. For the better supplying the moulding chamber or pressing tube with materials the measurer is discharged when over the cavity of the moulding chamber by means of the admission of steam or air under pressure.

In our engraving fig. 1 represents the elevation of the machine, part in section, with portion of framing removed. Fig. 2 represents the plan of the machine, also part in section, with the upper portion of one side removed. Fig. 3 is a section of plan of cylinder and pistons. Fig. 4 a transverse vertical section of discharging and measuring apparatus, and fig. 5 a transverse vertical section of moulding tube through dotted lines. A is the steam cylinder, B B the cylinder caps, C C the moulding tube, D the valve box or steam slide, E E the hopper, F the measurer, G the discharger, H the piston rod, I the plunger, J the ring or channel for conveying the palletts, *k k k* are palletts, *l l l* are blocks or bricks, M is the piston, and N plugs or pistons. By the reciprocating motion of the piston rod and plungers the measurer is caused to pass under the bottom of the hopper to be charged, and is brought back with the plunger over the charging cavity of the moulding chamber,

SELF-CONTAINED ENGINE AND BOILER.

BY MR. JOHN CAMERON.



and the materials ejected out of the measurer into the moulding chamber by the admission of steam, air, or gas, &c., into the chamber above marked G, fig. 4.

Many thousand tons of fuel have already been pressed in Wales by Mr. Fairburn's machines at the lowest possible cost. The minor difficulties which existed in working the original machines are now overcome by the present improvements. A peat machine with all the recent improvements is completed and at work pressing the peat in balls 4½in. in diameter at the rate of from 30 to 40 a minute, or equal to 50 tons per day. There are also two machines in the course of construction for pressing coal, and when completed will be set to work in South Wales. They are capable of pressing 100 tons of coal each per day, giving a pressure of 40 tons on each block. The fuel being moulded and pressed while under a high degree of heat (which forms the subject of another patent), removes any tendency to flying or giving off particles when thrown into the hot furnace. In bituminous coal the non-heating volatile gases, water, sulphur, &c., are driven off, thus making the fuel almost smokeless. The blocks are cooled in their passage (while under pressure) through the machine, and are at once ready for transit and shipment. We may mention that this machinery is applicable for brick-making, and several machines for this purpose are nearly completed. They are to be worked in Wales and in the neighbourhood of London. Each machine is capable of making from 18,000 to 20,000 bricks per day, under a pressure of 40 tons, at a very small cost. Plastic bricks can be put in the kilns immediately on leaving the machine, and need not be kept to dry as in ordinary cases.

CAMERON'S PORTABLE ENGINE.

IN our report upon the Manchester Show we promised a more extended notice of the self-contained engine and boiler exhibited by Mr. Cameron, of the Egerton-street Ironworks, Hulme, Manchester. We now annex an elevation of one of these engines, which are alike excellent in design and sound workmanship. They can be mounted on wheels, if desirable, instead of feet, and the exhibitor showed two so mounted, but he does not appear to advise their use in this way, for which, indeed, they are too heavy. The engine is fitted on a strong bedplate, which thereby relieves the boiler from its alternate working strains, an arrangement which conduces greatly to the durability of both. All parts of the engine are external and easily got at. There is but one guide bar, with a very wide bearing surface, in place of the four generally used. All the brass steps have square bottoms, so as to be easily lined-up when worn; the crank shaft neck steps tighten horizontally on both sides, in the direction of the working strain, by means of an ingenious arrangement of wedges fitting on the whole surface of the brasses; the steps next the flywheel are two and a-half diameters long. The ordinary over neck wrought-iron crank is preferred, on account of its simplicity, to the inside bent crank, as, in case of accident, it could be repaired by any clever workman in any part of the world, with the tools generally found in a smith's shop; this is an important consideration for exporters, emigrants, and the general user. The governor is driven by bevel wheels, and communicates with an equilibrium regulating valve. The feed pump is fitted with air vessels, and with a valve at the bottom of the suction pipe; it is fitted with ordinary conical seat valves in preference to the ball valve. The piston pump and valve rods are made of steel, and so is the crank shaft and pin. The boilers are cylindrical throughout, and no angle iron is used in their construction. They have cylindrical fire-boxes, communicating by tubes with the smoke-box. They are lagged all over, and fitted with a very strong man-hole in the top of the barrel near the middle, in which is fixed an eye bolt, by means of which the whole engine and boiler can be swung by a crane. The boiler has a complete double set of fittings—two safety valves, two glass water gauges, and two fusible plugs in fire tube. The engines are all made to a system, under which the pistons all run 300ft. per minute, and the circumferences of the flywheels all run 1,880ft. per minute, which enables an engine to be replaced by any other size without alteration of diameter, driving pulley, or speed of shafting.

CURRYING AND DRESSING LEATHER.

HITHERTO, in currying and dressing leather, it has been usual to employ neatsfoot oil or cod or fish oil, together with tallow. According to an invention lately patented by Messrs. Vanner and Prest, of 32, Great St. Helens, London, the residuum oil obtained when distilling petroleum is employed for this purpose. When the residuum oil is of a specific gravity of about ·880, which is about the specific gravity of the oil as now usually manufactured, it is used with tallow in the proportion of 14lb. of oil to 16lb. of tallow. By thus using the residuum oil in place of fish and other oils hitherto employed in currying and dressing leather, it will be found that the oil so combines with the tallow as to carry it almost wholly into the skin, and so forms a good stuffing, and also that it gives greater elasticity and more permanent weight to the skin than any oil now in use; it also renders the leather more impervious to water and less liable to decay or gum. The inventors employ the residuum oil obtained when distilling petroleum by the aid of a partial vacuum in a still heated by an internal steam coil. A mixture, consisting of fourteen parts of the residuum oil to sixteen parts of tallow, with two to three parts of cod oil added, to make the mixture more fluid, that it may work easier, will be found very suitable for dressing leather, or in cold weather less tallow might be employed. When using a stuffing composed of vacuum oil and tallow and cod oil, as above described, care should be taken in regard to the amount of stuffing used, for if too much is applied it will strike through, and make the grain of the leather dark. A currier will readily judge the amount necessary to apply if he bears in mind that the residuum oil so combines with the tallow as to carry it almost wholly into the skin.

ELECTRO-DEPOSITION OF COPPER AND BRASS.

An invention has recently been patented by Mr. W. H. Walenn, of 76, Brecknock-road, Holloway, for enabling the electro-deposition of copper and brass upon iron and other substances to be made with less battery power, with greater economy, and more solidly and perfectly than has hitherto been done. A solution for electro-depositing brass is made as follows:—Crystallized sulphate of zinc (1 part by weight) and crystallized nitrate of copper (2 parts) are dissolved in the smallest quantity of water that is possible. Sufficient strong ammonia water is added to precipitate and then fully redissolve the oxides. Then the purple tint of this solution is completely removed by a standard solution of cyanide of potassium. The resulting solution should be left to stand for a day or two, and may then be worked with from one to three battery cells, using heat if a brass anode be employed. Mr. Walenn, however, prefers to work this solution by either of the porous cell arrangements to be presently described, the hydrated oxides of copper and zinc being from time to time supplied, and, if necessary, ammoniuret of copper being added. Before adding the hydrated oxides, it is advantageous to add as much of the cyanides of the metals as will dissolve in the menstruum. Ammonia water and a standard solution of cyanide of potassium should be added occasionally to this depositing liquid in order to keep the salts of copper and zinc well in solution. The hydrated oxides of copper and zinc are mixed, and thoroughly incorporated in the proportion of 2 parts by weight of the hydrated oxide of copper to 1 part of the hydrated oxide of zinc before they are added to the solution. During working, little or no hydrogen should be evolved from the article.

A second solution for electro-depositing brass, chiefly useful where heat is used, but also able to be employed cold with a porous cell arrangement, is made as follows:—A solvent solution is first made consisting of,—

Cyanide of potassium (standard solution) -	6 parts by measure.
Nitrate of ammonium (standard solution) -	1 part.
Sulphate of ammonium (standard solution) -	2 parts.

The standard solution of each salt consists of the salt in the solid form dissolved in five times its weight of water. The standard solution of cyanide of potassium referred to in the description of the first electro-brassing solution is so made. Eight-ninths of the whole of the ingredients are mixed in order to receive to saturation the cyanides of copper and zinc previously mixed in the proportions of 3090 parts by weight of cupric cyanide to 1795 parts of zinc cyanide; the remaining one-ninth of the solvent solution is added as free solution to the eight-ninths. This mixture is then treated to the hydrated oxides of copper and zinc, as in the first solution, and the ammoniuret of copper is added if it is found that this solution evolves hydrogen gas during deposition. Previous to trial by the battery, the solution should be allowed to stand for one or two days. A few ounces (by measure) to the gallon of ammoniuret of copper will suffice to prevent the evolution of hydrogen gas. This method of mixing the solution is preferred to all others.

A modification of this second electro-brassing solution is made by mixing the whole of the solvent solution and then dividing it into three parts:—

Free solvent solution . . .	1 part.
Solution to dissolve cupric cyanide	$5\frac{1}{4}$ parts.
Solution to dissolve zinc cyanide .	$2\frac{3}{4}$ parts.

When the respective metallic cyanides have been dissolved to saturation in the portions of solvent solution appropriated to them, the free solution is added thereto, and the whole is thoroughly mixed. Ammoniuret of copper is then added, and the finished solution is allowed to stand for a day or two. Instead of using the cyanides of copper and zinc respectively, to charge the solvent solution with copper and zinc, oxides, carbonates, or other salts, compounds of the metals may be employed.

Another modification of this second electro-brassing solution, and one very nearly equal in quality to that first described, consists in charging the solvent solution with metal from a brass anode by electric power, using four Grove's cells of adequate size, and arranged for intensity for the purpose. After charging the solution with about two ounces of metal per gallon, the mixed cyanides are added, if it will dissolve any; then as much of the mixed oxides as it will dissolve; and, finally, to adjust the solution for the non-evolution of hydrogen, a small quantity of ammoniuret of copper. This adjustment may or may not be necessary. A serviceable modification of this solvent solution consists in employing equal parts of cyanide of potassium and sulphate of ammonium, and adding thereto one ounce (by weight) of crystals of nitrate of ammonium per gallon. The nitrate of ammonium is necessary, as it favours electric conduction, and tends to keep the solution in working order.

If a solution to electro-deposit copper be required, instead of charging the solvent solution with about one part of zinc to two parts of copper, it is charged with one part of zinc to ten or twenty parts of copper. This part of the invention refers to any alkaline solution, but more particularly to that containing cyanide of potassium and tartrate of ammonium, and to the two brass solutions described above. The addition of sulphate of zinc to acid solutions for electro-depositing copper has long been known to improve the quality of the deposit; the presence of zinc toughens the cupreous deposit. In a porous cell arrangement for electro-brassing or electro-coppering the surface of the solution next the zinc or other dissolving plate is at a greater elevation than that of the external or depositing solution. This plan tends to keep the depositing solution in working order.

The next part of Mr. Walenn's invention refers to rendering alkaline brass and copper electro-depositing solutions free from the evolution of hydrogen gas, during electro-deposition, thus enabling the whole of the electric power to be utilized and non-porous metal to be deposited. This is accomplished by adding to electro-brassing solutions, the hydrated oxides of copper and zinc in sufficient quantity for the purpose. Another method is to add simply ammoniuret of copper. In a third method, the hydrated oxides of copper and zinc are dissolved in ammonia water, and the resulting solution added to the depositing solution. In treating electro-coppering solutions, the hydrated oxide of zinc is not required. Although hydrated oxides are preferred, other oxides may be used.

The next improvement consists in applying to the brass and copper solutions mentioned above, the method of working them by the supply of the cyanides and hydrated oxides of the metal or metals, in conjunction with the use of a porous cell; to generate the electric power or to receive the same from an adequate battery, the cyanides and hydrated oxides either being stirred into the solution from time to time as required, or supplied from a tall porous cell containing an ammoniacal solution of the cyanides and hydrated oxides that acts by the pressure of the column of liquid in the said porous cell to force the ammoniacal liquid into the depositing solution outside the porous cell. When no separate battery is used, an amalgamated zinc plate in the porous cell furnishes the requisite electric current. The solution in the porous cell may be:—

1. The solvent solution of the second brass solution.
2. A mixture containing cyanide of potassium and sulphate of ammonium in solution, equal parts by weight preferred.
3. A solution of an alkaline chloride.
4. A solution of an alkaline sulphate.

When a separate battery is employed, a brass or copper plate in the porous cell as an anode, and immersed in the solvent solution of a brass or copper solution, enables a portion of the solution to be charged with brass or copper, whilst the other portion is parting with its brass to the cathode, and, by the alternate use of these solutions as depositing solutions, continuous working may be obtained.

The last improvement patented by Mr. Walenn consists in an acid solution for the electro-deposition of copper, which has not hitherto been used for that purpose. A few drops of bisulphide of carbon per gallon of solution (a larger proportion may be used) are mixed with a solution containing one pound of sulphate of copper to the gallon, and an ounce or two of sulphate of zinc to the gallon; it is essential that this solution should be acid. The effect of this solution is to deposit pure copper uniformly over the article to be coated of a silky and bright appearance. The solution is not liable to get out of order.

INTERCOMMUNICATION ON RAILWAY TRAINS.

The question of a means of communication between guards, engine drivers, and passengers on railways, has received the attention of Mr. James Leetch, of 11, Dowgate-hill, City, who has worked out and patented the following invention. It consists of a flexible galvanized iron wire rope or chain, attached by a new kind of pulley underneath the centre of the carriages, trucks, &c., each end being fitted with improved coupling hooks, for the purpose of connecting the communication between each carriage throughout the length of the train. Hitherto the great difficulty has been to effect communication through the entire length of the trains, allowing for the play of the buffers, yet easily worked, and at the same time capable of taking up the slack when the train is going down an incline. This essential object is accomplished by the introduction of a new but simple arrangement of elastic springs, permanently fitted to each end of every carriage, &c., having eyelet-holes through which the line of communication can freely work, and which continually keeps the entire line taut, or always on tension, whether the carriages are drawn asunder to the full extent of their coupling chains, or closed up together to the extent of the buffer springs. This novel method of taking up the slack has great advantages; each carriage has its own connecting line complete in itself, the springs contracting or expanding according to the action of every separate carriage, whether on gradients or rounding curves. To make up a train, the carriages are brought together in the usual way, the spring hooks are then coupled in a second, when a perfect connection is established throughout the whole length of the train, for the purpose of sounding the steam whistle on the engine and the bell in guard's van.

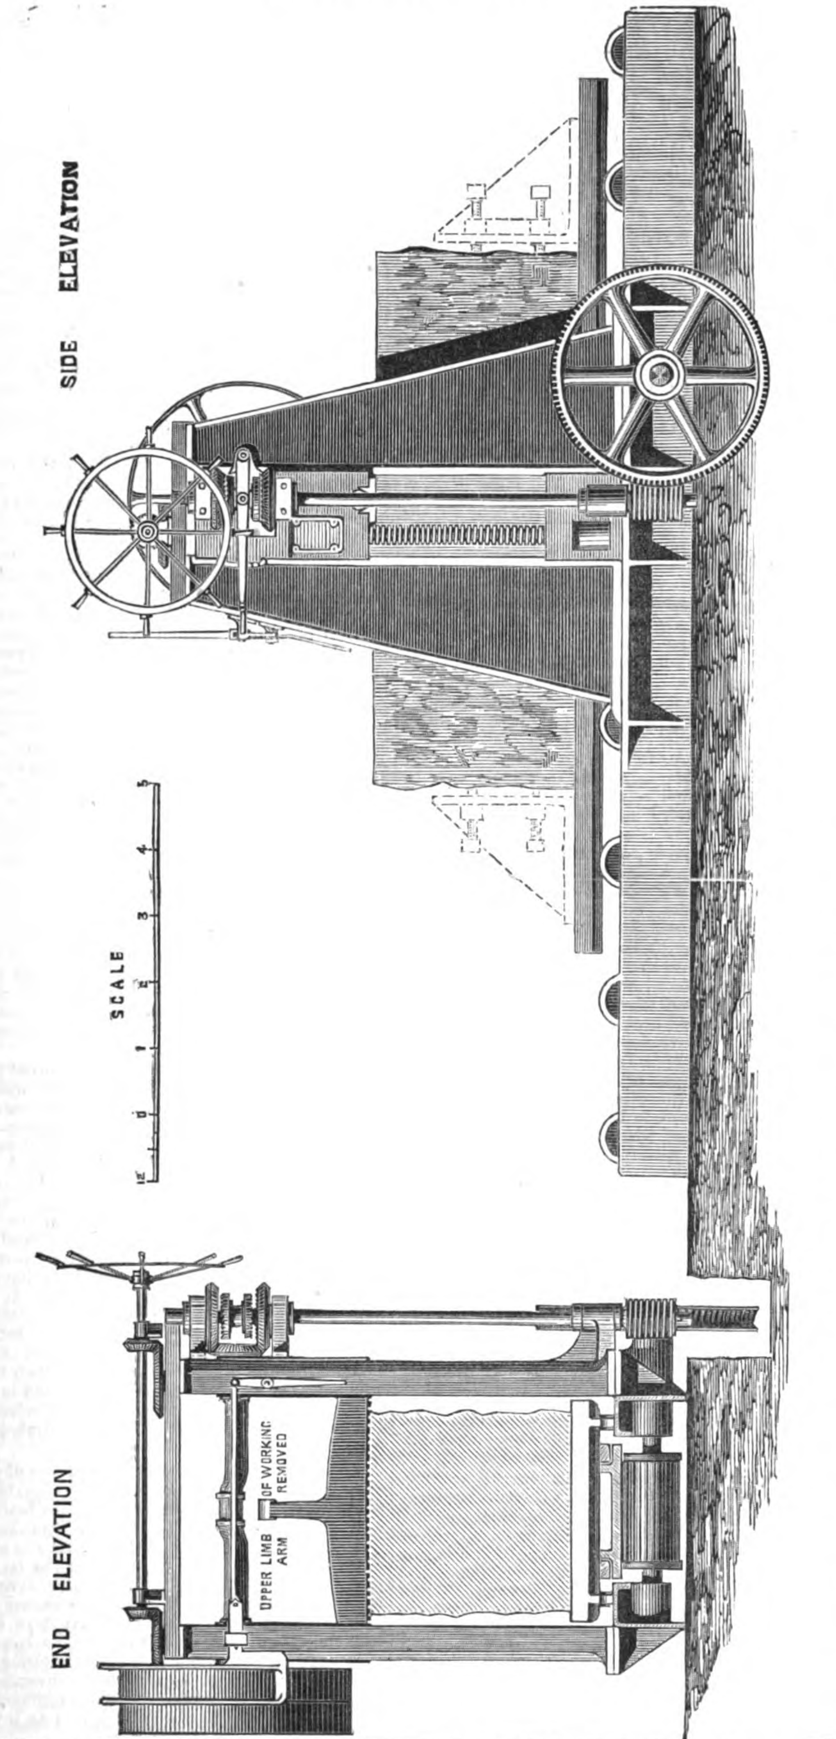
Attached to the through connecting line underneath the carriage is a strong wire, running over pulleys into each compartment encased with a handle like a bell-pull; should a passenger require to give an alarm, he has only to pull the handle down which is placed above his head, when the driver's whistle and guard's bell will be simultaneously heard at each end of the train, whatever length it may be. The guard and driver can communicate before starting, to prove that connection is complete, and can also telegraph with each other at any time while on the road. Each compartment is also provided with a self-acting indicator. The act of pulling down the handle of the centre signal sends out an arm on either or both sides of the carriage, where it remains locked till the guard returns it to its former place, which he can do in a moment, when it is again ready for use, but beyond the control of passengers. This self-acting tell-tale enables the guard to find the carriage in which the person is who either wants his assistance or who may have improperly used the danger signal. The advantages of this system are obvious. It is easily applied to the rolling stock on any line of railway, and uniformity can be obtained on all trains. There is no complicated machinery, it requires but little attention, and is not likely to become deranged. Curves cannot intercept its action, and if a carriage breaks loose from the train, the whistle and bell must necessarily be sounded by the separation.

HOLMES' STONE-DRESSING MACHINE.

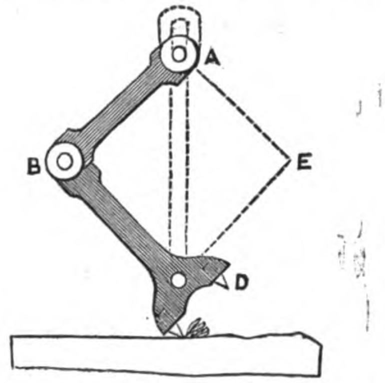
We last week noticed the successful application of machinery by Mr. Holmes to the dressing of stone, and the recent application of steam power for that purpose. We now publish engravings of the apparatus, to which the following description applies. Our readers will remember our illustrations of Mr. Holmes' hand machine a few months since. In that apparatus the cutters are arranged vertically; in the machine worked by steam power, however, they act horizontally; but the mechanism by which the cut is applied is essentially the same in each case. In another particular the two machines differ in action. In the hand machine the feed and the cut alternate with each other—the table rests while the cut is being given, and moves forward when the cutters rise from the surface that they are acting on; in the larger and more powerful machine the table travels continuously. The power is applied by a driving-belt direct from the engine to a rocking crank driving-shaft to which the cutters are attached. At the opposite end of this driving shaft is an arrangement of bevelled gearing, by which the cutters are put into or taken out of gear, and by which also the power is transmitted to a vertical spindle, which, by a worm-wheel, operates upon the travelling table. In working a block of Portland or other stone down to a rough level surface, two series of cutters are employed, and so adjusted that when the motion of the table is reversed the one set cuts away the ridges that

STEAM POWER STONE-DRESSING MACHINE.

BY MR. J. E. HOLMES.



have been left between the grooves cut by the other set. The spaces left between the faces of the chisels are wider than the cutting faces. For granite, black marble, and the harder kinds of stone, grooving points, rather than chisels, are used for the rough cutting-down to a uniform level. The finished tooling is by a broad chisel working across the entire face of the stone under treatment. The working arm and cutters are shown in the annexed diagram to an enlarged scale, from which their action may be gathered. The rocking shaft at A gives the scooping action to the range of cutters. When the stone ha passed for its whole length under the cutters th motion of the table is reversed, the pin at B is taken out, and the arms are joined again at E, and the cutters, or dressing tool, as the case may be, at D are brought into action. It is intended, we believe, to substitute screws for the roller wheels under the travelling table, with a view to more



firm and steady motion We have previously placed on record the results of working in this machine, which are highly satisfactory, both with regard to the work done in a given time as against hand labour, and also with respect to appearance and finish.

THE WHITWORTH SCHOLARSHIPS.

THE Lords' Committee of the Privy Council on Education have, in concert with Mr. Whitworth, made the following rules for awarding the Whitworth Scholarships this year, and for holding the examinations in handicrafts and in the practical use of tools.

It was decided that the Scholarships were to be awarded according to the results of the examination of the Science and Art Department in the following subjects, as defined in the Science Directory:—1. Elementary Mathematics; 2. Higher Mathematics; 3. Theoretical Mechanics; 4. Applied Mechanics; 5. Practical Plane and Solid Geometry; 6. Machine Construction and Drawing; 7. Acoustics, Light and Heat; 8. Magnetism and Electricity; 9. Inorganic Chemistry; 10. Metallurgy; and according to the skill shown by the competitors in a special examination in the following handicrafts—1. Smith's work; 2. Turning; 3. Filing and Fitting; 4. Pattern Making and Moulding, or in the use of the following classes of tools—the axe, the saw and plane, the hammer and chisel, the file, or the forge.

Mr. Whitworth desired that the number of marks obtainable in the theoretical subjects and those obtainable by the most skilled workman should be about equal; and it was decided that no candidate should be eligible to obtain a scholarship who had not shown a satisfactory knowledge of Elementary Mathematics, Elementary Mechanics, and Practical Plane and Solid Geometry, passed in Freehand Drawing, and proved his power to use one at least of the before-mentioned classes of tools. The relative position of candidates as regards the theoretical subjects will be determined by affixing the same scale of marks to the several grades of success as is laid down for the competition for Royal Exhibitions, viz.,—for a 3rd class in elementary stage, 1 mark; for a 2nd class in elementary stage, 3 marks; for a 1st class in elementary stage, 5 marks; for a 2nd class in advanced stage, 5 marks; if previously successful in elementary stage, 7 marks; for a 1st class in advanced stage, 7 marks; if previously successful in elementary stage, 9 marks; and 5, 4, 3, 2, and 1 marks in addition to the first five candidates in the advanced stage if they obtain more than 90 per cent. of marks. For honours, 2nd class, 14 marks; for honours, 1st class, 17; "good" in freehand drawing will count as 1 mark and "excellent" as 3 marks. The "satisfactory knowledge"* required for passing in the subjects mentioned in Section 3 will be taken to mean the obtaining of a first class in the elementary stage of elementary mathematics, a second class in the elementary stage of theoretical or applied mechanics, a second class in the elementary stage of practical plane and solid geometry, and a "good" in freehand drawing.

The results of the examination in all the theoretical subjects will be published about the middle of June. It will then be possible to define within comparatively narrow limits the candidates amongst whom the competition will really lie. These will be directed to hold themselves in readiness to undergo the practical examination, which will be

* The papers of candidates who have taken the honours papers and failed in obtaining a class will this year be specially considered, and if it shall appear that the candidates show such knowledge as would undoubtedly have placed them in the first class in the elementary stage, they will be passed—that is to say, they will be considered to have satisfied the condition of showing a "satisfactory knowledge," but no marks will be given for these papers in the competition.

conducted at a certain number of centres by qualified persons. The practical examination is of two kinds. There is the examination of the handicraftsman or skilled artizan, and there is the qualifying examination in the use of certain tools. The examiners will decide on the number of marks to be awarded, and the position of the skilled artizans by the rate of wages, &c., which they have been receiving (as vouched by the certificates of their employers), by work specially executed for the occasion, or by an inspection of work upon which they may have been employed. The examination in the use of tools will be the performance of one or more of the following pieces of work.

THE AXE.

a. To square up a block of wood 1ft. long and 6in. diameter.

b. To made a spoke for a cart wheel.

c. To be able to shaft an axe.

d. To cut out wheel spokes ready for fitting into nave.

THE SAW AND PLANE.

a. To saw from a plank two pieces of timber 3ft. long and 3in. square and plane them up true.

b. To make a box 18in. long × 9in. wide × 9in. deep, planed up true and the joints dovetailed together.

c. To saw out and plane up two parallel strips 2ft. × 2in. × in.

THE HAMMER AND CHISEL.

a. To chip a piece of cast iron 6in. square over on one of its surfaces ready for filing.

b. To cut out of sheet iron (any gauge) a figure or letter of any size from 1in. to 6in.

THE FILE.

a. To file two sides of a cast-iron 1-inch cube as flat as possible with a Stubbs' 12-inch second cut file, the stroke of the file not being less than 9in.

b. A wrought-iron hexagonal nut ½in. or 1in. to be filed up true.

c. To file up two parallel strips, iron or steel.

d. To file up pocket square as true as possible.

THE FORGE.

a. To weld or join together two pieces of iron ½in. square.

b. To make a pair of smith's tongs.

c. To make the head of a hammer.

d. To make a pick.

e. To make 2ft. ½in. chain with hook and ring.

f. To make a horse-shoe complete.

g. To cut off and draw out chipping chisel or drill and afterwards harden.

h. To make a pair of small callipers.

i. To make a pocket square.

A competitor is not restricted to one only of the handicrafts nor to the use of one class of tools; but he may show his skill in two or more. His position and the number of marks to be awarded to him will be determined by his general skilfulness as a workman. A skilled mechanic will thus be enabled to obtain credit and improve his position by showing his power of using those classes of tools not properly belonging to his own handicraft, and the ordinary student may in like manner, instead of simply qualifying in the use of a certain class of tools, show his skill in one of the handicrafts mentioned. To those who merely qualify in the use of tools, a certain proportion of the marks obtainable for practical workmanship will be given according to their relative skill. These marks will count towards the general result. The travelling expenses of poor students—2nd class railway fare with a personal allowance of 10s. per diem—will be allowed to enable them to attend at the places where the practical examinations are to be held.

MARKING INK PENCIL.

THE Crystal Palace has lent its name to a great variety of art products, both useful and ornamental. The latest application of this favourite prefix has been made to a new marking ink pencil, which formed the subject of a recent patent. Pencils of this class have hitherto required cutting, but the daughter of the late John Bond—of marking ink fame—has introduced one on the ever-pointed principle. A thin stick of solid ink is enclosed in a wooden casing, and is propelled forward as it becomes shortened by use. This secures a permanent point and obviates waste from cutting. It is convenient in use, and as unfailing in its results as Bond's liquid ink. We may here refer to the Crystal Palace marking ink pedestal, which is the most complete and compact marking apparatus we have seen. It contains a bottle of ink, a supply of special pens and a holder, and the top is arranged as a stretcher on which the material is fixed for marking. We should add that the manufactory for these useful articles is No. 75, Southgate-road, London.

ON the 3rd inst., the first stone of a monument to the celebrated German geographer Mercator, was laid with great solemnity at Duisburg.

THREE YEARS OF SHIPBUILDING.

A PARLIAMENTARY return, showing what vessels of above 50 tons have been built in the United Kingdom in the last three years, states that at the port of London, in 1866, 32 vessels, of 17,734 tons, were built; in 1867, 15, of 3,644 tons; in 1866, 11, of 6,607 tons. At Liverpool 38 vessels, of 23,667 tons, were built in 1866; 22, of 12,475 tons, in 1867; 44, of 50,247 tons, in 1868. At Glasgow, 121 vessels, of 68,134 tons in 1866; 95, of 52,865 tons, in 1867; 97, of 90,390 tons in 1868. At Sunderland 149 vessels, of 59,254 tons, in 1866; 128, of 47,625 tons in 1867; 131, of 64,374 tons, in 1868. At Greenock, 18 vessels, of 14,276 tons, in 1866; 22, of 8,532 tons, in 1867; 32, of 16,819 tons, in 1868. At Newcastle, 44 vessels of 27,961 tons, in 1866; 28, of 15,464 tons, in 1867; 27, of 19,031 tons, in 1868. At Port Glasgow, 24 vessels of 10,689 tons, in 1866; 22, of 11,709 tons, in 1867; 23, of 14,022 tons, in 1868. At Hull, 59 vessels, of 13,288 tons, in 1866; 22, of 7,266 tons, in 1867; 20, of 8,186 tons, in 1868. At Aberdeen, 16 vessels, of 11,471 tons, in 1866; 18, of 9,199 tons, in 1867; 15, of 7,924 tons, in 1868. At Shields, 88 vessels, of 13,548 tons, in 1866; 6, of 2,094 tons in 1867; 7, of 2,626 tons, in 1868. At South Shields, 19 vessels, of 5,087 tons, in 1866; 8, of 1,452 tons, in 1867; 5, of 2,099 tons, in 1868. At the Clyde Ports, at Liverpool, and at Sunderland the tonnage built in 1868 was greater than in 1866 and 1867; at the other ports it was less than in 1866.

PATENTS AND PATENT LAWS.*

By W. BRIDGES ADAMS.

THE word "monopoly" is one of exceeding ill-odour with the great mass of the community, and to affix such a name to patents is considered a very clever move on the part of their opponents. It catches the public ear, and the public is very apt to take things for granted that appear to conform to its interests. What is a monopoly? A privilege conferred upon special individuals, for their own advantage, to the disadvantage of the community. At first sight, numerous private rights appear to be monopolies—land, mines, forests, rivers, the raw material of the world, which are the property of the whole human race, as tenants in common; and for individuals to possess and own them as private property is simply a concession granted, because they will produce a generally greater fruit by the process of individual enclosure than by a general scramble. The conversion of the raw material into useful forms, by the operation of the human brain and human hands, creates another kind of property, giving the raw material far greater value by mental and physical labour, labour which would not be given unless the owners could reap some of the fruits of it by an enclosure of the results of their own brains or hands as their own property. Origination of new and useful ideas and forms, producing something better and more useful than has been produced before, is the most valuable kind of labour, and therefore the world, in proportion as it becomes civilized, gives exclusive property, for a longer or shorter time, to the producers of the ideas, and goes still further in giving hereditary rights to long-continued industry.

Language is common property; but the author of a book, putting language into new forms in combination with ideas, is endowed with what is called "copyright" for a term of years, a monopoly, in short, for the reason that, without that monopoly, the books would not be produced, or only a very few books would be produced by a few wealthy and powerful persons; and the very title of the book is also a monopoly. Another person produces a picture which has a high value, and the right to reproduce that picture by engravings, or photographs, or other means, is reserved to him. Another produces new combinations of musical sound, and the multiplication of copies of this music is as much his own property as the original. Another produces a piece of sculpture. with the same results. Another produces a new design for furniture, or patterns for dress, or other manufacture, and that is as much his own, with the exclusive right to sell it entire or in copies, as though it were the corn and cattle of the farmer, or the fruit of the orchard owner, or the vegetables of the market-gardener.

This monopoly goes still further. The style and title of a firm is private property; and, as if to guard against the contingency of the same Christian and surname in combination being used for competition by a namesake, trade-marks were invented to ensure the monopoly, and every possible means are resorted to, to prevent a trader's individuality from being trenched on by his neighbours. Yet more, a proprietor of a newspaper, with no individuality, and who purchases all his wares ready made from other persons, has the exclusive right to a particular word or combination of words out of a dictionary, which, if he be the first to assume, no one can appropriate till he chooses to abandon his right.

Throughout all these things it is the right of property which the law jealously guards, mental or other. But for this law, a large mass of mankind would disguise themselves in their neighbours' likeness, to reap the profits accruing from their neighbours' reputation. What are called patents are mental originations, multiplied in matter, and the law professes to confer on the originator the sole right to use and sell them to the public for the course of fourteen years. Some of these originations are very popular, and an enormous trade grows up, from which large profits accrue, and it is very commonly an article not of real importance to the welfare of the community that makes the largest profits; but whatever it may be, trade rivalry is excited, and any means are resorted to for evading the patent without payment to the inventor. Everything previously known in the trade is at the disposal of the rivals, but the Naboth's vineyard they covet is the new thing which the public prefer, either for its superiority or its cheapness, and which has been the production of the inventor's brain. So they set to work to defame him, to deny his originality, to call him a monopolist, to decry his invention, to try to evade it by inferior methods, and, finally, to take advantage of inefficient laws to plunge him into costly trials that may ruin him and put the invention out of use, if they cannot appropriate it to themselves without paying anything for the cost of its production.

A few years back, an attempt was made to decry and abolish patents at the meeting of the British Association, and now once more an attempt is making to obtain a huge monopoly, under pretext of abolishing another—not a monopoly as of old in the case of the Corn Laws, for the benefit of landlords or landowners, but for the supposed benefit of trade lords and capitalists generally. Large manufacturers, material converters, and similar people, desire to get the use of brains without paying for them, or to keep things as they are. It is not a case of patentees against the community, as their opponents endeavour to make out, but a case for the community itself, as interested in progress, against wealthy traders who would keep down all progress, if by so doing they could keep up their own profits. It is the case of the community, in behalf of the active brains that work for them with mental capital, and without material capital, against the dull and inert brains with material capital in masses, which at present, stimulated into competition by the restless brains around them, lead an uneasy life, and would fain become the slaveholders of the active brains, and prescribe limits to their labours under their own control, and for their own imaginary benefit. It is an attempt to create an hereditary trade aristocracy by taking away the fulcrum through which clear brains rise into the possession of material capital, and their owners elbow the inert rich from their seats. And not uncommonly, it is those who have grown rich upon patents who are the most strenuous opponents of other men's patents.

The common ground of opposition is that patents impede progress. If they did, that would be sufficient reason for their abolition. But assertion is not demonstration. It is asserted that the patent is a monopoly which no one but the owner can use. Quite true; but so is land a monopoly which no one but the owner can use, the difference being that the patent is a monopoly for fourteen years, and the land for ever. The patent is a fourteen years' monopoly of individual brainwork, the land monopoly is that of the material works of the Creator. If the land were the property of the State, the rentals would belong to the general community as a tax-fund, and the community gives it to individuals on the supposition that they will manage it better for the general benefit of the community than the State could, the rental being the payment for their trouble. The patent is a limited property, the land is an unlimited property, both conferred by the community, and capable of resumption if demonstrated to be mischievous to the community.

The brain-worker can only, in the case of patents operate by the agency of matter, the property of the landlord, who exacts a large share of the brain-work in return for the use of the matter. But the brain-working patentee has no monopoly. He is exposed to the competition of all others using the landlord's matter or the materials of the Creator, save in the patentee's particular mode. And no sooner has he achieved a success than other inventors are immediately at work to eclipse him, to the benefit and advantage of the public; and it is notorious that, even in the case of a successful invention not superseded by another improvement, commonly half the fourteen years' term expires before an invention is brought even into limited use.

The large manufacturer has his choice of patents by competition amongst brains, saying nothing of the stored-up records of lapsed patents at the Patent Office, which he rarely has recourse to, save to compete with, and defeat, something new, which a rival manufacturer has produced under a patent, and turned to profit. It is well known that few manufacturers will embark in new things without the protection of a patent, for the reason that money must

* Journal of the Society of Arts.

be expended experimentally, and that rivals lie in ambush to reap the profits in competition, without outlay, and consequently can undersell the originator, and for this reason the records of lapsed patents in the Patent Office are not resorted to, but remain dead letters.

It has been sought to make a distinction between copyright and patent right. There is none; they are alike, in their integrity, original emanations of the human mind, and we may be quite sure that the abolition of patents would soon be followed by the abolition of copyright in books or works of art. Copyright in designs is copyright in a representation. Patent right is copyright in form, and utility, and methods of production; whether brain imagination be multiplied in printed books, or in music, or in engraving, or artistry, or design, or theatrical exhibitions or shows, or stamped on matter under what are called patents, it is the same process of expressing mind in matter as an origination; and as the originators are comparatively few in number, it is desirable to cultivate them, and give them enclosures of mental domains wherein to have free scope for the exercise of their various arts, for precisely the same reasons that the enclosures and private ownership of land—a common property—is granted to the producers of food, and for other purposes.

It is simply the system of bad laws to which all the evils of patents are traceable. There was a time when, amongst the manufacturers of printed fabrics, all new designs were kept secret as far as possible till the moment of issue, and all were busy bribing, or trying to bribe, their neighbours' designers. The Act for copyright in designs abolished this system of piracy, and with it the secrecy. Were patents abolished, one of the results would be a return to secrecy in all small things, a closing of manufactories against inspection, and a general dearth of information to mechanical periodicals, while improvements, involving a large outlay of capital, would cease to be made, unless perchance in Government establishments. If the spread of knowledge be a national advantage, the inducement to secrecy by the abolition of the patent—OPEN—would be a serious evil.

Amongst the reasons alleged for the abolition of patents, one is, that the patentees gain no advantage —being ruined by opposition and law suits in case of the invention being successful. This is the greatest farce of all, as if land property would be safer than brain property, were it protected by as bad and inefficient laws as patents are subjected to, and as if there were any difficulty in making as efficient laws for patents as for books and designs, were only influential men interested in bringing them to pass, and lawyers not interested against them. Another allegation is, that the great mass of modern patents are useless. If they are useless they need not be coveted. If impedimental, they certainly must supply something useful. But it is again alleged that they are frivolous. But is not trade itself widely frivolous? Yet what merchant is there who despises anything frivolous, provided only large profit be mixed up with it? What is more frivolous than the majority of theatrical farces, yet what is there more carefully guarded against piracy? But, say the objectors, patents are granted for things not new, and merely serve as an excuse for lawsuits. That simply means that the law and practice have not yet been fitly established. Some say that patents are becoming so numerous that they cannot keep count of them, and so unwittingly infringe them. This is not logical. The patentee might as well object. "The great manufacturers make so many new things without giving me notice, that I cannot keep count as to my originality." This complaint on the part of manufacturers only proves that they manage their business badly. It is surely part of the business of a great manufacturer to know of everything produced in his special art, and, therefore, he should keep a book of patents as regularly as his price-list, with a managing clerk to it. He can, at small cost, have all the specifications in his trade supplied to him as fast as they come out, and he can index them and mark out all the real novelties and utilities, and put them to use by agreement with the owner. It is said that every British subject is bound to know all the laws, or take the consequence of breaking them, and certainly a British manufacturer is bound to know all the patents in his trade as part of his business.

All existing knowledge and manufacturing experience up to the present time is the joint property of the whole nation, less certain things protected by patents expiring in fourteen years. But these patents are the "Naboth's vineyard," coveted by the lords of trade. But they may fairly say that amongst the numerous patents there are many fictitious ones, involving lawsuits, and thus deterring them from the use of what is really common stock. That is to say, the patent laws are bad laws, so bad, that were all laws equally bad, the nation would be in a condition of anarchy. To abolish the patents instead of to reform the law would be a precedent upon which we might abolish all laws.

Let us begin at the beginning. Patents are virtually granted for something new and useful, thereby to teach the public, and the reward for such teaching is a fourteen years' exclusive right. What, then, is novelty? "There is nothing new under the sun," absolutely. The patent is really granted for something new to the existing generation, as an inducement for a skilled man to bring it into use. The title should, therefore, be put on a similar footing to that of land. A piece of unowned land unclaimed for thirty years becomes the property of whoever may occupy it, and for ever. Therefore, supposing patents to be in the interest of progress, absence of public use for thirty years should constitute a claim to anything useful as a novelty for fourteen years, or such time as might be deemed equitable.

Everybody of legal age should be competent to apply for and obtain a patent, but as any preliminary examination and refusal might involve an accusation of nepotism or a contingency of error, not afterwards to be amended, it is desirable that protection should be granted, if desired by the applicant, after pointing out to him the defects; and that the specification, after completion, should be put on open, not secret, trial, by a competent judge, in the presence of the patentee, and the original fees should cover this cost. It is not desirable that a model should be put in at first, as involving the employment of workmen and the risk of discovery before protection is granted; and models being expensive, it is not fair to encumber the patentee with costs. The affirmation of the patent by the court should facilitate all further litigation as to title and right, the court itself taking the initiative, or acting at the instance of a complainant. Pecuniary damages should be dealt with by a magistrate, as in the case of copyrights, or by the ordinary courts of law. Fictitious patents abolished by the court would cease to be a nuisance in the hands of sharking pretenders. There are very few patents requiring deep thought to apprehend them when produced, or any length of time when legal quibbling is abolished. An inventor should not be bound to licence other persons, for the reason that they might be rivals, only taking a licence in order to damage his invention in public reputation. If an unreasonable man, he would damage himself by limiting the use. If a manufacturer, he might be interested in selling at the lowest price without royalty profit, and thus, as a small capitalist, he might compete with great capitalists by securing the trade in a better article.

If the invention were a small item in a large machine, and the inventor required an unreasonable royalty, that would simply be a stimulus to other inventors to make other improvements, and this would be clearly in the interest of the public. In cases where the subject of a patent has been in private use previous to the specification, unknown to the patentee, it would become a question for the court to decide as to whether the public had been kept out of the knowledge furnished by the patentee, and, if so, the patent should be confirmed, subject to the use of the first user, but without giving to him the right to licence earned by the patentee by his publication. No excuse of ignorance of a patent should be admitted as a plea or mitigation of infringement, because, with the full means of obtaining the records of the Patent Office, the ignorance must arise either from wilfulness or negligence.

Patents are the Magna Charta of the material progress of a nation, by the agency of the rich brains of men, poor in practical capital, who can mould matter to man's uses after new and useful fashions, just as copyright is the Magna Charta of the nation's progress by the agency of men of rich brains who can mould language to men's uses after new and useful fashions. When laws shall be made to take away this charter and throw brains into common stock, one of the sources of England's eminence, her true equality, will have departed from us, and the trade lords will find that their vitality has departed with it. They will compete with each other with increasing competition and lowering profits, till their trade becomes as wild land, which no one cares to cultivate. They will then find that the fourteen years' mental enclosure, which induces men of thought to bring forth new things, is also one of the processes essential to profit, and that by abolishing it they "kill the goose which lays the golden eggs." Trade-marks are the legitimate arms and quarterings of a trade aristocracy, guarantees of honesty in execution, and which become valueless as a manufacture becomes debased. They are monopolies in one sense, as they enable the owners to keep to themselves a large trade so long as they keep up their character, and the law now jealously deals with their infringers. The patent is also a trade-mark exclusive for fourteen years, enabling the owner to establish a reputation for originality and improvement, and to keep his reputation when thrown into competition with rivals. And with patents confined to the owners of manufactories, that would simply be establishing a caste of veritable monopolists.

The question has been dealt with thus far simply in the interest of the public, regarding the inventor merely as a part of the public. But the true inventors are more than this—they are a select body of students, who foresee those things that the manufacturing men of routine pass by blindfolded, and thus stir them up to action; and the public is deeply interested in caring for these men, and guarding their interests as their own. From the trade point of view, the mere manufacturer only looks to the profit percentage attainable by the conversion of raw material into wrought, and would work up the whole raw material of the land, and afterwards throw it into the sea, if realizing the percentage thereby. It is this class of men that deteriorates our national manufactures in money competition, that makes rails as brittle as cast iron, and delights in shoddy, that has no perception of, or care for progress, but only for money. It is not thus that the greatness of England has grown; nor is it of the highest importance that inventors should reap enormous fortunes, albeit trifling in proportion to the gain to the general community; but it is desirable that they should be in the unanxious position requisite for the most advantageous pursuit of their studies and experiments, as a result of their own labours. The nation in which all classes of its people can rise in succession, according to their faculties and cultivation, from the lowest position to the highest, must ever be more powerful than a nation of castes, and a nation without laws efficiently protecting mental as well as physical property must degenerate into a land of castes—or robbers.

There is yet another allegation on the part of opponents of patents. Having to pay a royalty in England, other nations paying no royalty can undersell them. It is scarcely so, for other nations are as desirous of having patents as English people are. Of the two republics, America and Switzerland, the former abounds with patents, the latter has none. The reason is, that in the former case they are a function of the Federal government, in the latter of every separate canton, rendering patents a practical impossibility. But citizens of Switzerland expatriate themselves, and get patents here and elsewhere, and it is probable that the patent branch of legislation will be transferred to the Federal government, and Switzerland will cease to be an exception to other civilized states. With a climate and condition like that of England, where workmen live longer and do more days' work in every year than in most other countries, it is impossible that she should be undersold in her indigenous manufactures, so long as her materials shall endure. Capital embarked in the growth and training of a workman is profitable in proportion to the length of his working life, and the faithful and honest work produced.

The assumption that every patentee only forestalls a number of other persons, who would have discovered or planned the same thing, may or may not be true, but this does not concern the public. What the public want is individuals who will work, and teach in the best mode they can, something new and useful; and daily experience tells us that such individuals cannot be obtained save on the condition of thereby obtaining a specific sphere of action involving their own benefit as well as that of the public. Let any one try if, by simply publishing a new and useful thing, he can get it taken up unless he can offer an exclusive right with it. Neither is there any probability in the assumption that all the principles of action have been discovered, and that the details are in every one's hands. The tree of universal knowledge is yet far from having been plucked, and it is to be desired, that the men of science, as well as the men of practice, should be not only recognized but rewarded, as the benefactors of the community—not rewarded, as M. Chevalier proposed, by the State, but by the community. We do not want political inventors, with a government reward as a compensation for something other than an invention, and with their own friends to apportion it. We want for them the only true appreciator, the public.

There is no difficulty in remedying all the evils complained of in the present practice of patents. Forms of specifications can be prepared, embodying everything that is required to be stated, leaving no loopholes, and preventing verbiage, giving an exclusive privilege to make something useful, and leaving it open to competition to make something still better. The life of the inventor patentee is no lazy life. He has the public for a master, and a very exacting master too, content with nothing but the best or the cheapest, and ever ready to abandon its idol of to-day for its idol of to-morrow, succeeding each other in constant following. What do the long list of patents in the same arts mean, save that the human brain works only from step to step, eclipsing yesterday by to-day, and thus preparing the way for the morrow, a 'vantage ground being gradually attained, till the process culminates in an apparent perfection, at last found to be no perfection, when a fresh start is made to a new elevation. By the sweat of the brain within his brow the inventor diminishes human labour and the sweat of many brows, for his only profit is out of the service he renders to mankind, who will not pay for anything they do not appreciate as useful or pleasant. No State reward is needed as a stimulus to this kind of labour. The inventor only asks to be let alone to reap the crops he has himself sown, secure against depredation.

It was Prince Albert by whom the amended Patent Law, then being worked at by the Society of Arts, was finally urged, and it was Lord Granville who brought in the Bill and passed it through Parliament, in the course of a very few days, because it was believed that only thus could a number of latent inventors amongst mechanical men be brought to

light for the benefit of the Great Exhibition. It was this bill which, by reducing first cost, multiplied the number of patents, and put poor men more on a level with capitalists. And it would appear that non-inventive capitalists would rather be without these patentees, and would prefer to buy up their inventions for their own purposes, and so limit the public choice in the market. Patents give a large market for constant improvements, which would not exist without them. All the large manufacturing towns and cities of England may be said to be built upon patents, and were patents abolished, the result would be similar to that of the abolition of the Edict of Nantes; the imaginative brains would depart from England, and settle down in the countries wise enough to understand their true interests. Viewed from the monopoly point, the wisest course the manufacturers could take would be, not to abolish patents, but to enhance their cost. If patents cost £5,000 each, with efficient laws to maintain them, every poor man would be shut cut, and patents would become the practical monopoly that the manufacturers insist on calling them. But the motive would thus be too gross.

The subject cannot be too widely discussed, nor the facts elicited too clearly, for we cannot, as a nation, afford to risk our prosperity in order that a small number may grow richer at the general cost. We want a general diffusion of wealth, and not a greater aggregation in masses. Large manufacturers tend to the growth of quantity rather than quality. Small manufacturers tend to the growth of quality, and that diffusion of wealth so largely trenched on of late by the gigantic establishments which permit only two classes, the very rich and the very poor. The higher classes, living on incomes the result of land or hoarded wealth, are deeply interested in the question, for it is a question of property right; and in the diffusion of property rather than in its concentration lies its safety. The convenience or profit of manufacturers is but a small consideration, as well as the convénience or profits of inventors. The national prosperity is the real question at issue. Shrewd Frenchmen tell us that we began patents some fifty years before them, and, therefore, they have never been able to overtake us. Were we now to abolish patents for fifty years, our human energy would be expended in producing original workers for all other nations, and excluding our own.

TREATING WOOD FOR MANUFACTURING PAPER.

An invention has been patented by Dr. Matthieson, chemical lecturer of St. Bartholomew's Hospital, which relates to the preparation and treatment of fibrous materials suitable for the production of paper. The wood when in a state of division, such as shavings, sawdust, or disintegrated wood, is submitted to what is known as a retting process, that is, the wood in a state of division is steeped either in running or stagnant water, and is allowed to undergo a retting or fermenting process, by which certain constituents of the wood will be decomposed and removed, and the subsequent treatment of the residual ligneous fibre for the production of pulp or paper will be thereby rendered more economical, and the process of boiling and bleaching be more easily effected. The time necessary for effecting the process of retting will depend upon the temperature of the water and the nature and state of division of the wood operated upon; the higher the temperature the shorter is the time required.

Dr. Matthieson also submits the wood when in a disintegrated or divided state to the repeated and successive action of water at a temperature below 212deg. Fah., in order that those constituents which are soluble in water may be removed either before or subsequently to the retting process. By this additional process the ligneous fibre is rendered better capable of being more economically treated by any of the processes usually employed for the boiling and bleaching of the ligneous fibres and materials which are employed in the production of pulp or paper. The ligneous material, after having undergone either or both of the processes before described, is submitted to the action of an alkaline ley and to the processes of boiling and bleaching.

In the third place, the inventor submits timber or wood in bulk, either at the ordinary or at an elevated temperature, to the action of water or of an alkaline solution in a manner similar to that which is known as the Boucherie process, and at such a pressure as that the water or the alkaline solution shall purge the cells and other portions of the vegetable structure from the sap and other fluid constituents contained therein. The timber or wood thus purified may then be employed for the production of paper in the manner as hereinbefore described or otherwise. These processes may be applied to either dry or seasoned wood or to green or fresh wood, preference being given to the latter.

Correspondence.

BOTTLE-SHAPED CARTRIDGES.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—I am told that cartridges of a bottle form are now being made for the Martini-Henry rifle and that they were used in that arm at the lat Wimbledon meeting. I should be glad if you o any of your readers can inform me if this statemen is correct, and also if this form of cartridge ha been previously proposed or used.—I am, Sir, yours, &c., J. B.

London, August 18.

[We are not aware that the bottle-shaped cartridge is being made for the Martini-Henry rifle, nor do we think it was fired at Wimbledon. At any rate, we did not meet with it at any of the firing points. This form of cartridge is no novelty; for several years past it has been made in copper for the Spencer repeating rifle. It was also adopted by Colonel Boxer in some of his cartridges before the rifle competition, and cartridges on this principle are now largely manufactured by Messrs. Eley Brothers, some we have by us being stamped "Eley-Boxer patent."—Ed. M.M.]

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the Mechanics' Magazine. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, Mechanics' Magazine Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the Mechanics' Magazine, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Naval, Military, and Gunnery Items.

It has been decided that there will be no examination in December next for admission to the Royal Military College, Sandhurst.

A War-office return shows that in the year 1868 2,524 men were enrolled in Great Britain under the Militia Reserve Act; and in 1869 6,589 men had been enrolled at the end of July.

Advices have been received that the "Aerial" and "Lahloo," tea ships, left Foo-chow on July 2, and the "Leander" and "Thermopylæ" on the following day. The latter two vessels are the favourites in China for the annual "tea race."

By an Act of Parliament just printed power is given to remove military prisoners to Millbank to be treated as other prisoners. Regulations may be made for the treatment of military offenders at Millbank Prison.

The Admiralty flag will be hoisted on the forthcoming cruise on board Her Majesty's ironclad ship "Agincourt." The First Lord of the Admiralty will be accompanied by Vice-Admiral Sir Sydney Dacres, K.C.B., Captain Beauchamp Seymour, C.B., and Captain Willes, C.B.

Orders have been received at Chatham dockyard from the Admiralty, directing the construction of a target of great weight and thickness of armour plating, to be used in the experiments intended to be carried out at Shoeburyness to test the effects of vertical firing.

The Supervising Inspector of Navigation for the Eighth District, which comprises the great lakes on the northern boundary of the United States, has just made public his report of disasters during the year 1868. The statistics are as follows:—Passengers carried, 900,000; lives lost from fire, 73; from collision, 51; from wreck, 26; from explosion, 1; making a total of 151. The accidents were 19 in number, as follows:—Collision, 8; fire, 6; striking on sandbars or rocks, 3; foundering, 2. Of the fires, five were of vessels burnt at night while lying at the dock.

In connection with the King's Lynn dock, recently inaugurated by his Royal Highness the Prince of Wales, it may be remarked that the contractor (Mr. Lawrence) has pledged himself to complete the railway which will bring the dock into communication with the Great Eastern and Midland system by January 1, 1870. A warehouse on the south side of the dock is making good progress, and a commencement has been made with the construction of a series of four warehouses on the north side. It is expected that the Midland Railway will deliver 50,000 tons of coal annually for exportation from the dock.

We note in the "Birmingham Post" that Mr. A. Somerville, of the firm of Braendlin, Somerville, and Co., has been created by the King of Italy a chevalier of the order of St. Maurice and St. Lazarus. Mr. Somerville's firm are the patentees of the Albini-Braendlin rifle adopted by the Italian and Belgian governments, and Mr. Somerville, who is now in Italy, has lately effected an improvement in revolvers, adapted for use of cavalry regiments. Some Italian officers, we are told, pointed out to him that the revolver is comparatively useless to cavalry, because mounted soldiers cannot easily take aim. To meet this objection Mr. Somerville caused the ball to be cut into four, six, or more pieces of equal size, and these being fitted together were re-introduced into the cartridge in the same manner as a single bullet. This experiment, we learn, proved very successful, the charge when fired scattering like grape shot and the revolver being thus altered into a mitrailleur.

Miscellanea.

The Berlin Committee has received subscriptions to the amount of 5,166 thalers for the purpose of erecting a monument to Alexander von Humboldt.

The number of public Acts passed in the recent session was 117, against 130 in the preceding year. In the session just ended the local statutes numbered 182, and in the last year 159.

With regret we record the death, at the age of 71 years, of Mr. Edward Barrow, for nearly 40 years a member of the literary staff of the "Morning Herald," and for several years of that of the "Standard."

The number of visitors to the Patent Office Museum, South Kensington, for the week ending August 14, was 4,591. Total number since the opening of the Museum, free daily (May 12, 1858), 1,621,616.

A New Zealand paper says that several specimens of Taranaki steel have been taken to England, smelted from the Taranaki steel sand, which is said to contain 75 per cent. pure steel. Samples of both crude and manufactured have been sent.

In the years 1863, 1864, 1865, and up to June 30, 1866, 85 tigers, 365 cheetas and panthers, 72 bears, and 61 hyenas, were destroyed by Shikarees in the district of Vizagapatam, and in that period the reward for the skin of a tiger was raised from 35 rupees to 100 rupees.

We understand that the emigration of Cornish miners continues, more than 50 having left the country during the past week. The cause is, not want of employment, but the low rate of wages. Unfortunately, the miners who are emigrating are mostly of the best class.

A recent telegram from Ajaccio states that the domanial forest of Mormano has been on fire since the 8th. Measures had been taken by the troops quartered at the penitentiary establishment of Casabianca, close by, to extinguish the flames, but the attempt failed and the conflagration was still spreading.

The Great Western Railway Company have given notice of the suspension of their traffic between Hereford and Ross from to-morrow night till the 23rd inst., in order that the line may be converted from the broad to the narrow gauge. The line between Ross and Grange Court will be closed from August 23 to August 31 for the same purpose.

A letter from Rio Janeiro says that, owing to the bad reputation of nitro-glycerine, a small quantity in the military arsenal there was ordered to be thrown into the bay. Six ten-pound cans were put into a boat and taken out 250 yards. The first one thrown out exploded on striking the water, and the concussion set off the others. The boat was blown to pieces, and all the crew, seven persons, killed.

The number of visitors to the South Kensington Museum during the week ending August 14, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 14,871; Meyrick and other galleries, 3,132; on Wednesday, Thursday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,805; Meyrick and other galleries, 209; total, 20,017. Average of corresponding week in former years, 12,087. Total from opening of Museum, 8,695,818.

According to a report in the "Industrial Alsacien," a shocking accident occurred a few days ago in a quarry on the territory of Bollingen, about a league from Berne. A piece of rock upwards of 80 yards high suddenly gave way and fell upon some men who were working at the time, overwhelming them under a mass of rubbish. Fifteen were found to be missing. Eight bodies were immediately dug out in a dreadful state of mutilation, and no hope was entertained of finding the others alive.

At a general meeting of the Royal Horticultural Society, held on Tuesday, Mr. W. Wilson Saunders, F.R.S., in the chair—Mrs. J. Humphrey and Henry Whitworth were elected fellows. Among the objects of interest shown was a magnificent specimen of lilium auratum (on which were over 150 blooms) from the gardens of the Dowager Lady Ashburton. The Council specially awarded the Lindley Medal to this fine plant. Mr. Bull exhibited a gigantic aroid, the property of Dr. Seemann. Messrs. Kelway and Sons' collection of gladioli and Mr. Chater's collection of hollyhocks were deservedly admired.

The British Consul at Chee-foo reports that the wild silkworm is bred in large quantities by the country people of Shan-tung, and a great deal of wild silk is produced annually in the neighbourhood of Chee-foo, in the central part of the province, and in the vicinity of Tsi-nan-foo. The silk cloth made from this wild silk is brought to Che-foo for sale. It is used by the Chinese for summer clothing, is very strong, and wears extremely well. It is thought probable that the wild silkworm may be acclimatized in Europe, and attention has been drawn to it both in Italy and France. Che-foo can furnish the eggs of both the wild and the domestic silkworms.

The mining industry in Queensland is in a very satisfactory condition, and is rapidly acquiring increased importance, in consequence of the frequent discoveries of mineral wealth that are being made. This progress has made itself more especially felt within the last year. By the statement of imports and exports to the colony during 1868, it appears that the largest increase in the exports has been in the value of gold. In 1867, the amount was £189,248; last year it was £593,516, which shows an increase of £404,268 on last year's operations in this direction. The value of the exports of copper and copper ore has increased during the same time from £66,038 in 1867, to £72,136 in 1868.

It used to be the boast of England, says the "New York Times," that on its empire the sun never sets. Well, we have an empire on which the sun only sets occasionally. Mr. Seward, at San Francisco, expressed the greatest interest in viewing for the first time the broad Pacific; at Sitka, for which he has set out, he will find a novelty which not a dozen persons in the old States have ever seen. In that latitude the sun does not set at all in summer. It remains about 25deg. above the horizon at the hour we call midnight. The only mode of knowing there that it is midnight is to watch the sun when it begins to ascend. Fowls go to roost at 7 p.m., and repose until the sun is well up. In winter it is, of course, the reverse, as in the higher latitudes the sun is not seen for six weeks.

One of the last Acts of Parliament, rendered necessary by the recent fearful accident, was passed to prohibit, for a limited period, the importation and to restrict and regulate the carriage of nitro-glycerine. Save as mentioned, no person, after the passing of this Act, is to bring into any port or harbour of the United Kingdom, or ship or unship on, from, or near the coasts of any part of the United Kingdom, any nitro-glycerine. By acting in contravention to the provisions the party is to be guilty of a misdemeanour, and liable to be imprisoned, with or without hard labour, for one year, and all nitro-glycerine brought into any port is to be forfeited. New regulations are to be made as to the manufacture, sale, and carriage of nitro-glycerine, and notice of nitro-glycerine is to be given, and search permitted for the article.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

Boilers and Furnaces—144, 179, 191, 209
Buildings and Building Materials—154, 163, 170, 197, 198, 206, 214
Chemistry and Photography—148, 186
Cultivation of the Soil, including agricultural implements and machines—177, 190, 193, 199, 217
Electrical Apparatus.—216
Fibrous Fabrics, including machinery for treating fibre pulp, paper, &c.—138, 147, 150, 153, 155, 157, 158, 169, 184, 200, 204, 205, 207, 218.
Food and Beverages, including the apparatus for preparing food for men and animals—142
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c.—135, 146, 151, 152, 156, 185, 187, 194
General Machinery—145, 159, 165, 183, 195, 203, 210, 215
Lighting, Heating, and Ventilating—162, 186, 208
Metals, including apparatus for their manufacture—139, 149
Miscellaneous—134, 140, 141, 164, 167, 171, 173, 178, 180, 181, 188, 192, 201, 202, 211, 212, 216
Roads and Vehicles, including railway plant and carriages, saddlery, and harness, &c.—136, 137, 160, 172, 175, 182, 189, 213, 3888
Ships and Boats, including their fittings—143, 160, 168, 174
Steam Engines—196
Warfare—166, 176

3888 W. Pidding, Walcot-square. *Locomotion.* Dated October 21, 1868.
This consists in placing and affixing in naves equidistant bow-shaped double spokes with their hollows facing each other connected together at their extreme ends. Projecting from the ends of such spokes, alternately of different lengths and at right angles with them, are to be placed and fixed bolts or studs for the purpose of their being made to pass through sideways, and to partially rotate between the centres of rails placed in parallel lines, and almost in close contact at their ends. The disconnected rails are to be secured at their ends in pairs by elastic bands or fastenings, to allow of their movement when progressing and turning on to the feet or chairs described in the patentee's specification of the patent, No. 14,036, dated March 24, 1852. The naves in connection with the portable rails hereinbefore described are to be placed on axles affixed to the vehicle immediately over their ordinary wheels, and in such manner as to encircle them in such manner that the rotating surfaces of such wheels shall always be in contact with one of the parallel lines of the disconnected rails.—Patent abandoned.

134 A. H. A. Durant, Shepherd's Bush. *Manufacture of oil.* Dated January 15, 1869.
In the first place, the inventor winnows or removes the husk of the seeds or berries by the percussive force of blades or fans thereon, such blades or fans having a rotary action communicated by steam or other power for the purpose. The seeds or berries fall through sieves or feeders, so that the blades or fans strike them in their descent with sufficient force to break the husk or shell, and the albumen is afterwards removed from the husked seeds by boiling them in water, or immersing them in hot or cold water, and agitating them therein for a sufficient time; but it is preferred to use boiling or hot water, and in some cases 10 per cent. of nitric, sulphuric or other suitable acid is added to the water, for the last mentioned purpose. The seeds or berries thus husked and cleansed are then crushed and the oil expressed therefrom in the ordinary way.—Patent abandoned.

135 T. A. Warrington, Kentish Town. *Spoons.* Dated January 16, 1869.
The inventor makes the bowl of the spoon with an extension on one side formed as a continuation of the bowl, for guiding or directing the soup or other food into the mouth, and he constructs it with a curved bridge, guard, or plate formed with a ledge, and which guard or plate bridges or spans the bowl of the spoon in the direction of its length, thereby deflecting the hair of the upper lip from the bowl of the spoon, but nevertheless having suitable openings at each side so as to allow of the ready admission and emission of the soup, or other liquid food, to and from the bowl or body of the spoon. The bridge, guard, or plate may, if preferred, be hinged at one end, to facilitate the cleaning of the spoon.—Patent abandoned.

136 J. T. Bentley, Kendal. *Permanent way.* Dated January 16, 1869.
This consists in the use or employment, in combination with the fish plates and bolts at present ordinarily employed, of a device taking into suitable openings or recesses made in the webs of the rails in such manner as to ensure the formation of a perfectly even and continuously rigid road or way which shall not be liable to deflect at those points where the ends of the respective lengths of rails meet one another.—Patent abandoned.

137 S. Russell, Brixton. *Velocipedes.* Dated January 16, 1869.
The inventor constructs a carriage with a driving wheel placed at one end, whilst the other end is supported by a pair of steering wheels. The frame of the carriage is made of a triangular form, both vertically and horizontally, which enables the driving wheel to be held very steadily.—Patent completed.

138 R. Craig, Dalkeith. *Paper.* Dated January 16, 1869.
This consists in the application to paper-making machines of a roll or roller coated with vulcanite and with vulcanized india-rubber, and which roll or roller is substituted for the ordinary iron, brass, or other metal under press roll of the paper machine, and may be used as an under or upper second press roller.—Patent completed.

139 J. Jeavons, Sheffield. *Iron and steel.* Dated January 16, 1869.
In order to decarburize the iron while in a molten state in the puddling furnace, a vessel of suitable size attached to the end of a bar or rubble is filled with nitrate of soda and oxide of iron, or other suitable substance containing and capable of evolving oxygen. The vessel is then moved about under the surface of the molten metal, the result being that oxygen is evolved from the material contained in such vessel, and the same combined with the carbon in the molten metal, and according to the extent of the operation produces such quality as may be desired.—Patent abandoned.

140 J. G. Johnson, Warwick. *Signal apparatus.* Dated January 16, 1869.
When the improved signalling apparatus is intended to be used upon a railway or tramway, it is conveniently applied by attaching to a convenient frame or support fixed by the side of the railway or tramway, a signal arm, and also an index pointer and dial in such a manner that the tyres of the wheel of the passing engine or carriage, or some part of the engine or carriage, may act upon a bar, which acts upon a cam so as to give motion through a connecting rod and lever to a rod attached to the frame or support. To one end of the rod is attached a rack, and and at the other end is a piston working in a suitable cylinder like that of a force pump. The rod on being raised or lowered acts upon and turns a pinion which carries with the signal arm, and also the index pointer, which moves on the face of the dial like that of a clock. The passing engine or carriage acts by means of the levers and rod above mentioned upon the pinion wheel and so upon the signal arm and index pointer, which are thereby set at a given position, for example, so that the index pointer points to zero on the dial plate. The rod and with it the piston being raised produces a vacuum in the cylinder, which is connected with a suitable small reservoir or vessel containing water or other fluid. The fluid rushes in through the suction pipe and fills the cylinder. The piston and signal rod, and any necessary weight that may be attached to them, begin then to press upon the water or other fluid contained in the cylinder with a constant and uniform pressure. The water or other fluid is then allowed to flow out of the cylinder through a small aperture at a given speed, which may be regulated by any suitable valve. As the fluid issues, the piston descends and moves the signal arm and the index pointer on the clock dial at any given rate.—Patent completed.

141 J. H. Johnson, Lincoln's Inn. *Casks, &c.* (A communication). Dated January 16, 1869.
The object is to remedy certain defects which exist in the manufacture of casks by hand, to which machines hitherto proposed to be used in that manufacture, are liable. They relate to a series of machines intended to shape with the greatest rapidity and the requisite accuracy the different parts of which casks, tubs, and other like receptacles of any required dimensions are formed. At each operation the stave is worked according to the form it is required to have when the cask is put together, which principle admits of producing casks and tubs equal in quality to those made by hand. It should be observed that all the wood is first cut to the required length, width, and thickness, in the ordinary manner.—Patent completed.

142 H. A. Silver, Bishopsgate-street. *Cooking apparatus.* Dated January 16, 1869.
This consists in the combination of a vessel having a jacket or inner lining of tin, copper, tinned iron, or other suitable material, in the inner space or compartment of which is a dry heat with an outer case or heat retainer, constructed in the manner described in the specification of a patent granted to H. A. Bonneville, dated August 23, 1867 (No. 2417).—Patent completed.

143 John Bourne, Leith. *Propelling vessels.* Dated January 16, 1869.
Instead of propelling a vessel wholly by a screw or screws or by paddles, in the usual manner, the inventor propels her partly by a screw or screws or by paddles, and partly by a jet or jets of water, steam, air, or other gases, or by a mixture of all or any of them, the said jet or jets issuing sternward, and the screw or screws or paddles acting in conjunction or combination with the jet or jets in the propulsion of the ship.—Patent completed.

144 J. Loader and W. H. Childe, Finsbury. *Steam boilers.* Dated January 16, 1869.
The inventors employ a shell or boiler strong enough to withstand the strain, and they place therein a steam chamber of corresponding form, so that a water space is left all round the chamber between it and the shell. This chamber is made steamtight, except at the top, where an opening is made to receive a tube which is fitted steamtight to the chamber; the tube is open at the top or is perforated near the top. As soon as steam is generated it passes through the opening or perforations of the tube into the steam chamber. The steam chamber may be situated either above or below the water line, and may be fixed or allowed to float.—Patent completed.

145 W. and S. Bottomley, Rochdale. *Couplings for rollers, &c.* Dated January 16, 1869.
This consists in turning a round end on one roller, which end has a thread or screw formed on it; this round end fits into a round hole, and the thread or screw is screwed into this round hole in the other roller, thus coupling them together.—Patent abandoned.

146 W. Thomas, Cheapside. *Boots and shoes.* Dated January 16, 1869.
This consists in making boots and shoes as follows:—To the flesh side of the inner sole, prepared by thinning it round the edge, an inner welt of leather or other suitable material is sewn. The sole is then secured with its grain side to a last, and after turning up the edge of the inner welt, the upper is drawn on to the last, the stiffener inserted, and the upper and the outer welt are sewn to the turned-up edge of the inner welt; the welts and upper are then beaten flat to the last, the waist is stiffened by the insertion of the filling or shank piece, and the outer sole is sewn to the outer welt. The boot is afterwards finished in the usual manner.—Patent completed.

147 J. B. Whitehall, Nottingham. *Machinery for looped fabrics.* Dated January 16, 1869.
This consists in applying to each head a toothed wheel which turns with the head and gears into a wheel secured on the lower end of an axle which is held in a bearing secured to one arm of a standard to the right of the head. The upper end of the axle carries a circular plate which is furnished on its lower side with a presser plate which is shaped slightly eccentric for the purpose of adjustment. This presser revolves once round during two revolutions of the circular head. Above the toothed wheel, on the pipe of the head, and also revolving with it, is another wheel which drives a wheel half its size. This wheel is held on the lower end of a short shaft by a set screw; the shaft turns in bearings screwed to a standard at the left side of the head, the upper end of the shaft carries a wheel the same size as the wheel which drives a wheel twice its size, which wheel is supported by a collar under it secured to the pipe of a circular grooved cam held by screws to an arm secured to the top of the standard at the left of the head.—Patent completed.

148 F. Braby, Camberwell. *Sulphate of ammonia.* Dated January 16, 1869.
This consists, principally, in the employment of copperas

or green vitriol in the manufacture of sulphate of ammonia for commercial purposes instead of using sulphuric acid for that purpose, as has hitherto been generally practised. For this purpose, according to one process, the copperas is reduced to a solution by water, to facilitate which it may be ground or pulverized, and it is then added to gas liquor, or the copperas may be reduced to a solution by means of the gas liquor itself.—Patent completed.

149 L. B. PHILLIPS, Queen-square. *Metal fac-similes* Dated January 16, 1869.

The inventor first takes a fac-simile of the object to be copied by the usual methods employed to obtain an electrotype in copper or other metal or alloy. This fac-simile will be found to be an exact reverse of the original, but should a fac-simile of the reverse of the original be required the usual electro or other reversing processes must be employed previous to casting, so that the mould bears the original either in relief or intaglio as the case may be; and it is this electrotype which is to be used as a mould or matrix into or upon which the metal or alloy is to be poured or flushed by heat, the usual fluxes being employed for that purpose.—Patent abandoned.

150 W. R. LAKE, Southampton-buildings. *Figured shawls.* Dated January 16, 1869.

The warp is made up of one thread of each of the colours of the ground of the figuring; as, for example, one red and one blue, one green and one black. The warp may be of diverse nature, such as wool, two-fold yarn or wool, and raw or net silk. The arrangement and mounting of the loom may be performed in two ways according as it is desired to produce a figured serge fabric or a figured taffeta. In the mounting for the serge the beeting or tie-up is of combined cords. The first hook raises the mails or loops which are thus engaged therein. Weave together upon fifteen leaves, sinking and rising one thread of each colour, say one red, one white, one blue, one green, one black. The tie-up for the figured taffeta is of simple cords and regular, and there is a single mail or loop to each hook. Weave together for five threads one of each colour, as for instance, one red, one white, one blue, one green, and one black. Then regular or together upon ten leaves sinking and rising.—Patent completed.

151 M. HENRY, Fleet-street. *Mouldings.* Dated January 16, 1869.

A mould, countermould, or cast of the article to be moulded is first taken from the pattern, and sand or other ordinary moulding substance is pressed into the mould to form a core. The thickness which the intended casting is to have is determined or regulated by taking off a sufficient quantity of material to correspond with such thickness from the outer surface of the core. Another mould, countermould, or cast is taken from this core and filled with sand, or like moulding agent, so that a second core is obtained and so on, and thus any desired number of similar cores may be obtained. The cores are used to form the holes or hollows of the article, but they are combined with the employment of a plaster or such like mould or shell to form the outer part thereof. For this purpose the first mould or countermould together with a core, both produced as above described, is used, and thus a complete mould is obtained in which the spaces between the core and countermould correspond with the intended thickness of metal of the casting.—Patent completed.

152 W. PIDDING, Walcot-square, Surrey. *Mosaics.* Dated January 18, 1869.

The textile or other fabric to be used is saturated with starchy, glutinous, or other stiffening matter. It is then placed on a suitable frame, table, or other appliance, and pierced or perforated, the perforations being close together and equidistant. The perforating apparatus used consists of numerous sharp pointed wire fixed permanently and nearly close together in flat boards or other suitable material; these wires are to be taper in form and thicker at their base, so that when they are inserted into the fabric the fabrics may be distended as much as possible. The piercing or puncturing apparatus is to remain in the fabric until the same is dry and then to be extracted. To facilitate such operation it is preferred that the wires of the perforating apparatus shall be greased.—Patent abandoned.

153 W. H. PLATT, Ashton. *Looms.* Dated January 18, 1869.

This consists in the hole to receive the head of the pin or tongue a distance equal to the depth of the same, the bottom of the shuttle underneath the head by this means being left solid. Into this solid part a recess is made parallel to the bottom of the shuttle, into which a metal plate is inserted that forms a slight yielding metallic surface or bed against which the head of the pin bears, thereby strengthening the shuttle and at the same time making the frictional surface against which the pin head bears more durable, or the recess may be carried through and a supporting pin placed underneath. In order to place the cop upon the shuttle tongue or pin with the greatest ease the inventor slightly inclines or curves the end of the spring, now well-known and extensively employed for retaining the cop upon this curved portion, a fixed pin is caused to press when the pin or tongue is opened, which depresses the spring so as to make it lie flat with the pin, allowing thereby the ready placing on of the cop, but when closing the cop in the shuttle, the curved end of the spring being free from the pressure of the fixed pin allows the pin to bulge or swell out and press against the interior surface of the cop, by which means the cop is firmly retained until finally run out during moving.—Patent abandoned.

154 N. VOICE, Handcross. *Closets and urinals.* Dated January 18, 1869.

This consists of a mechanical arrangement for operating the pan valve of waterclosets, and for regulating the supply of water thereto by the simple opening and closing of the closet door. The arrangement consists of sliding rods or bars connected to the door and by an arm to the valve lever, so that when the door is opened the rods and arm cause the valve lever to rise or move, whereby the pan valve is lowered and the valve for admitting water to the basin is opened, and again, when the door is closed, the valve lever is lowered or returned and the reverse action takes place. The valve lever may be weighted so as to return the parts to their normal position, and close the door when pressure is removed from the door, but as the weight for this purpose would have to be heavy, the inventor prefers to fit a strong spring to the door so as to keep the same closed when not pushed or pulled open.—Patent completed.

155 C. CALOW, Burnley. *Looms.* Dated January 18, 1869.

This relates, first, to an improved "letting off" motion, and consists in supporting the lower shedding roller or centres, or points, one at each end of the roller, so as to allow the said roller free vibration "to and fro." These are used in connection with the ordinary eccentric for working the same. Second, or instead of the eccentric, the inventor attaches at one or both ends of the shedding roller or vibrator a curved or cranked link, to the lower end of which is secured the ordinary weighting or beam chain; the curved or cranked link admits any desired degree of vibration by allowing more motion or "play" to the vibrator in the direction of the stay.—Patent abandoned.

156 J. D. THOMAS, Liverpool. *Artificial bust.* Dated January 18, 1869.

The inventor forms the whole of the parts of air proof or nearly air proof materials, the back, or that portion worn next to the person, being made of a rigid or stiffish material, such as cardboard, vulcanite, or other hardened india-rubber, and the front or raised portion of a flexible material, such as india-rubber, or other so-called air proof cloth. The inflating is effected, preferably, in an atmosphere of about 60deg. Fah., or air or other gas at that temperature is admitted before the parts are permanently closed.—Patent abandoned.

157 P. OLDFIELD, Bradford. *Wool combing.* Dated January 18, 1869.

The spiral skew or twist of the flutes may be made in one or more revolutions or circuits around the rollers as betwixt one end and the other thereof, or they may be in less than one circuit or only form part of a circuit. Also, instead of the flutes continuing to run spirally in one direction, they may run partly in one direction and partly in the other, in a curvilinear manner, as in curve lines upon a cylindrical surface.—Patent completed.

158 R. H. CLARKE, Evesham. *Silk cloths.* Dated January 18, 1869.

This consists in applying an equal strain or tension to the ends of these cloths as well as to the sides thereof, whereby the proper square or shape of the perforations is preserved, the desired quality and quantity of meal and flour obtained, and the process of dressing more speedily accomplished.—Patent abandoned.

159 G. R. POSTLETHWAITE, Birmingham. *Screw nuts, bolts, &c.* Dated January 18, 1869.

On the bed of the machine a series of dies or tools is stationed, immediately over which other movable dies or tools work. Each fixed die or tool forms with the movable one over it a pair of dies or tools. By the use of the series of pairs of dies or tools described, a piece of iron is cut off the end of a heated bar, and the cut off piece is shaped and partly punched, further shaped, and finished, the complete punching of the nut being effected by hand immediately after the part punching by the machinery. The dies or tools on the bed of the machine are dropped into holes in vertical slides, the bottom of each slide resting on the short end of a lever. The longer end of the lever constitutes a treadle on which the workman puts his foot to raise the slide sufficiently to bring the nut within the operation of the movable upper die or tool. The height to which each of the slides can rise is regulated by a stop screw. Besides the lever described, a second lever is connected with each vertical slide at about its middle, the short end of the second lever passing through a slot to the bottom of the holes in the axis of the slide. By depressing the lever, a rod, commonly called a "upper," in the hole is raised, and made to project from the die or tool. The slides described turn upon joints near their lower ends, to permit of their inclining forward for the removal of bolts and other long articles.—Patent completed.

160 J. W. PRICE, Abergavenny. *Horses' nails.* Dated January 18, 1869.

This consists in providing a machine employed in this manufacture with a special furnace, through which the nail rod is passed continuously before arriving at the anvil or anvils; also in an automatic feed motion for propelling the nail rod, and in the employment in such machines of two distinct anvils and hammers, one of which anvils is stationary and the other movable. One of these anvils has formed on its face a die, representing in section a nail on its side, and the other a die representing a nail on its flat, or these dies may be formed on the faces of the hammer of the respective anvils, or partly in the hammer and partly in the anvil in each case.—Patent completed.

161 W. R. LAKE, Southampton-buildings. *Propelling machinery.* Dated January 18, 1869.

This consists, first, as relates to water propulsion, in the peculiar combination of the dynamic lever with a pair of piston propellers, whereby the inventor is enabled to apply the power so as to overcome the resistance of a vessel's immersed cross section without overcoming the resistance of the water at the propellers, and by so doing reduce the slip to a fraction. Second, as applied to land locomotion in the adaptation and use made of a series of two or more toothed wheels, so arranged as to give multiplied velocity and continuous pressure of any requisite amount, and acting upon a pair of large driving wheels attached to any vehicle, and put in motion by means of weights, or by being connected with any steam engine for the purpose of economical locomotion.—Patent abandoned.

162 G. BROWN, Edinburgh. *Gas meters, &c.* Dated January 18, 1869.

The meter consists of a compartment made in cast iron and of the filling tube, which serves the purpose of conducting water into the meter. There is a cylinder at the back of the front box, and an endless screw fixed to the cylinder spindle. A toothed wheel is fixed to the upright spindle, and a tube or channel made in cast iron, and known as the upright spindle tube, serves the purpose of letting the upright spindle tube project upwards into the index box. The lower end of the tube dips into the water in the meter to prevent gas from escaping, while its upper end projects into the index box to prevent the overflow of water. A tube or channel is made in cast iron, and known as the water line tube, through which all surplus water flows out of the cylinder compartment into the waste water box.—Patent completed.

163 J. H. JOHNSON, Lincoln's Inn. *Burning bricks.* (A communication.) Dated January 18, 1869.

The essential feature of this invention consists in so constructing a brick kiln that the products of combustion from fires contained in furnaces at one end of the kiln are caused to forcibly permeate the mass of bricks by the action of jets of steam or other equivalent exhausting device, situate at the opposite end of the kiln and *vice versa*, the products of combustion being caused to pass through the mass from one end to the other of the kiln, first in one direction and then in the opposite direction, thereby heating the bricks uniformly throughout. Jets of steam are also directed into the combustion chambers and over the fuel of those fireplaces which are in action for the time being, as well as into their corresponding ashpits.—Patent completed.

164 A. M. CLARK, Chancery-lane. *Refining sugar.* (A communication.) Dated January 18, 1869.

The mode of treatment forming the subject of this invention is based on the decomposition of the molasses by an energetic acid contained in alcohol, but in such a diluted condition that the sugar may remain in solution, while, instead of precipitating it by means of acetone, ether, or other agent, the sugar is obtained direct by crystallization. The following is the mode of operation:—The inventor takes 1cwt. of spent molasses, marking when cold 45deg. Beaume, and about 20 gallons of alcohol at 85deg., with the addition of about 5 per cent. of sulphuric acid. The alcohol used may be more highly concentrated, but in this case the suitable apparatus containing a stirrer for a few moments when it becomes perfectly homogeneous, and is then filtered in order to separate the mineral salts formed. In this condition the alcoholic liquor containing on the one hand the sugar in solution, and on the other the acids displaced by the energetic acid employed retains the sugar, which remains dissolved in the alcohol, marking 85deg., the latter being diluted by the whole of the water contained in the molasses.—Patent completed.

165 H. and J. PARNALL, Bristol. *Weighing machines* Dated January 18, 1869.

The inventors cut or cast sockets or cavities in the bearings, and apply the agate or other hard stone by inserting it within such cavities and fixing it therein by an adhesive material or compound; and on each side of the agate, transversely to the line of the pivot or movable bearing, they apply a steel plate set between the agate and the sides of the socket; the surfaces or edges of these two plates are made concave and at a lower level in the centre than the curvilinear surface of the agate, leaving the shoulders of the pivot to merely bear against the sides of the plates.—Patent completed.

166 W. T. ELEY, Gray's Inn-road. *Cartridge cases* Dated January 18, 1869.

When it is desired to employ a cartridge which will hold a charge of powder considerable in proportion to the bore of the weapon, the powder chamber of the cartridge case is formed of larger diameter than that part of the cartridge which embraces the bullet or projectile. Where metal cartridge cases, or cartridge cases formed from a coil of metal, alone or combined with paper, are employed, formed as above described with a larger chamber to contain the powder, the neck or smaller diameter of the cartridge case is formed by means of a die or dies, so arranged as to form flutes or folds in the case and so allow of the reduction of its diameter.—Patent completed.

167 S. G. ARCHIBALD, Edinburgh. *Cleaning boots.* Dated January 19, 1869.

This consists of a frame having bearings in which a spindle or axle is mounted, provided with treadle motion or crank handle or other arrangements, in order that the movement may be given thereto as may be required. On this spindle or axle the inventor fits brushes for cleaning boots, shoes, and other articles requiring brushing. He also provides for cleaning knives, forks, spoons, and other articles by fitting on to the axle or spindle suitably formed rolls or pieces covered with chamois or buff leather or other suitable material; and for sharpening he sometimes provides each axle or spindle with a sharpening roller or stone. In order to provide for portability and compactness he sometimes uses pieces of chamois leather or other material attached to spindles, which are turned by direct action of the hand, as occasion may require.—Patent completed.

168 M. BURKE, Liverpool. *Ships' skylights.* Dated January 19, 1869.

This consists in so constructing the top sashes or frames of ships' skylights that they are capable of a double action—that is to say, each sash or frame is free to be raised or opened in the ordinary way for ventilation, and, in addition, is free to be moved outwards and downwards, so as to leave the space usually covered by it perfectly open, and thereby admit freer ventilation when required, as is the case in warm climates. For this purpose the inventor employs two levers for each sash, one at each lateral end thereof. These levers are connected at their upper ends to the ridge or longitudinal top rail of the skylight by a joint or hinge, and at their lower ends to the bottom of the sash by another joint. When a sash is raised in the usual way motion takes place on the joints at or near the ridge or top rail, but when the space is to be left free motion takes place on the lower joints, the sash being as aforesaid moved outwards and downwards, and in this latter case it rests close to the side of the skylight.—Patent abandoned.

169 G. LOURY, Salford. *Hackling machines.* Dated January 19, 1869.

This consists in applying certain apparatus to the brush roller situated below the sheet of hackles, which brush roller takes off the tow the hackles have combed out of the flax. At intervals on the circumference or periphery of the brush roller is placed a rod or stripper, so arranged that when the said roller is made to revolve the rod or stripper strikes outward from the centre of the roller and doffs the tow from the bristles of the brush; the stripper then recedes towards the centre of roller until the brush is past the hackles, when the before-described operation is repeated.—Patent completed.

170 W. and J. PAIN, Stepney. *Flooring cramp.* Dated January 19, 1869.

This improved floor-dog is composed of a metal plate, having a boss pierced with a slightly inclined screw tapped hole, through which passes a screw, the head of which is perforated to receive the end of a lever, and the opposite end socketed in a foot plate. The metal plate traversed by the screw also carries two gripping levers bolted loosely on its under side, the plate being pierced with several holes so that the pivoting of the grippers may be shifted at pleasure.—Patent completed.

171 H. W. HAMMOND, Princes-street. *Mechanism for driving piles.* Dated January 19, 1869.

This consists in applying the force of gunpowder or

other explosive materials to act between a cap or cylinder upon the pile to be driven, and a ram or hammer, arranged in suitable guides so as to force the pile downwards and the ram upwards, the ram being arrested and held at its greatest elevation by means of a rack and pawl until the next blow is required, when it is allowed to fall, and by its fall to drive the pile and explode the charge in the cylinder, which still further forces down the pile, and at the same time lifts the ram for the next blow.—Patent completed.

172 J. Armstrong, Masborough. *Crossings and switch apparatus.* Dated January 19, 1869.

This relates, first, to improvements in crossings for the permanent way of railways. For this purpose the inventor first makes a casting to the shape, or nearly so, of the crossing required, and he afterwards rolls, hammers, or otherwise works it to the desired shape, as is well understood, but instead of afterwards splitting the ends into two, as has before been attempted, he forms the casting with divisions to the extent required from the end thereof, so as to obviate the necessity of cutting them up after they have been sufficiently worked.—Patent completed.

173 C. Baunscheidt, Endenich, Prussia. *Instrument for rheumatics.* Dated January 19, 1869.

This instrument for the cure or alleviation of rheumatics consists of a metal or other block or disc, from the face of which project a number of needles of equal length. This metal block or puncturer is enclosed in a suitable casing provided with a hollow stem or neck, through which passes a spiral spring, attached to the back of the needle block, said spring terminating in a handle which projects from the end of the stem. The block is retained within the casing by a raised rim formed on the interior, and the open end is provided with a cover for the protection of the needles when not in use.—Patent completed.

174 N. D. Spartali, Liverpool. *Apparatus for propelling vessels.* Dated January 19, 1869.

The inventor proposes to obtain a stream or streams of water, and to set the same in motion by means of apparatus which consists of a vertical cylinder fitted with a piston, the rod of which carries a crosshead. This crosshead works in fixed guides, and pendent from its ends are rods which connect with the beams of a steam engine of the ordinary construction. The cylinder is fitted at bottom or at its sides below the external water line with valves which serve to admit water thereto. The water will enter by its own gravity through pipes leading either from below or through the sides of the vessel. At its rear side this cylinder connects with a taper tube, which extends beyond the stern of the vessel and some distance below the water level. This tube, which the inventor terms the propelling tube, he prefers, after expanding somewhat like a trumpet tube, should suddenly contract slightly at its mouth, in order to ensure that the stream of water issuing from the tube shall escape with a proper degree of rush or impetuosity.—Patent completed.

175 W. R. Lake, Southampton-buildings. *Railway carriage wheels.* (A communication.) Dated January 19, 1869.

The invention has particular reference to introducing cushions of rubber between the hub or the body of the wheel and the tire thereof, so that the hub or the body of the wheel is not only supported relatively to the tire against elastic cushions, so that both in radial directions and torsionally the direct strain comes upon the cushions, but is so bolted relatively to the tire that while the parts are securely fastened together wear cannot come upon the bolts.—Patent completed.

176 C. E. Brooman, Fleet-street. *Breech-loaders.* (A communication.) Dated January 19, 1869.

This consists in constructing the ring employed in closing the breech of guns of large calibre as hereafter described. The invention is an improvement upon that patented by L. W. Broadwell, on April 29, 1865. In the specification of that patent, the ring was described as recessed in the bore, and an annular chamber was formed in the face of the ring. The inventor now constructs the ring with a curved exterior forming part of a sphere, the bore of the gun being formed to correspond. The annular chamber is dispensed with, and thus no space remains for powder residuum or other dirt to lodge in. A cut or recess is formed on the inner face of the ring in order that, should it become fixed in the barrel, a tool can be employed to move it.—Patent completed.

177 G. A. Crow, Newcastle-upon-Tyne. *Radial drilling machines.* Dated January 20, 1869.

This consists of a combination of movable tables, whereby the work to be drilled after being fixed can be turned round or placed either horizontally, vertically, or at any angle, thereby reducing the time and labour of adjusting such work. The improvements first consist in a hinged or jointed table, which is made to move to and from the horizontal or vertical line either by a screw or other mechanical appliance. Second, in the application of a table to this hinged or jointed table with a bearing in or attached to it, and constructed so as make an entire or any part of a revolution as may be required, and is moved to and from the vertical or horizontal line together with the first named table.—Patent completed.

178 J. Siddeley and F. N. Mackay, Liverpool. *Ice making.* Dated January 20, 1869.

This consists, first, in the employment in connection with apparatus in which ether or other volatile liquid is evaporated in vacuo, of currents of cold air as means for producing certain new and beneficial results in cooling, refrigerating, and ice making. The inventors apply the currents of cold air, first, to carry off heat from troughs or vessels containing pure water to be frozen into ice, by passing the current of air through the enclosed space or apartment containing the said troughs or vessels, or by passing it through a passage or channel formed around the outer sides of the trough; second, to carry off heat from water or other liquid passing through or in contact with a tubular or other refrigerator, and thereby lowering such water or other liquid sufficiently in temperature to render it suitable for cooling in another refrigerator worts or other liquids which do not require a very low temperature; third, to carry off heat from worts or other liquids by surface contact, that is to say, passing the current of cold air through a refrigerator formed with tubes or passages, the worts or other liquid being either inside or outside the tubes, but separated from the air by the thickness of metal; fourth, to carry off heat from worts or other liquids by impelling or drawing the current of cold air in immediate contact with the worts or other liquids to be cooled through a closed vessel; and, fifth, to carry off heat from other condensers and effect condensation of the ether. This is accomplished by passing such current of cold air either inside or outside of the pipes or other parts of, or over the metallic surfaces, in the ether condensers.—Patent completed.

179 F. A. Paget, Adelphi. *Steam boilers.* Dated January 20, 1869.

Above and below the main horizontal boiler, and by preference parallel, and in the same vertical plane, are set up two other boilers, preferably of a diameter less than that of the main intermediate boiler. This central boiler is that in which the steam is principally formed, and whence it makes its way up into the boiler above where it is collected and superheated. The feed water is forced into the lower boiler, whence it passes into the central or main boiler. The water thus partly fills the main boiler and entirely the bottom boiler. —Patent completed.

180 W. Gillet and C. Bland, Croydon. *Bell and clock chimes.* Dated January 20, 1869.

Where separate mechanism is employed for raising or otherwise moving or preparing hammers or other appliances for action, the inventors arrange rotating or other cams or moving contrivances (which they prefer to be rods or bars arranged around a central axis) at the end of the levers upon which they act. This cam or moving contrivance they so arrange as to act directly upon the lever which is connected with and actuates the hammer or other appliance, in place of upon a lever kept in constant movement. They arrange a tumbler or movable piece at the end of the lever for the cam or moving contrivance to act upon, in order to move the lever and place the hammer or other appliance in readiness. After the lever has been so acted upon, the tumbler moves away from the cam or other moving contrivance, so as to allow the lever to move, and the striker or other appliance to act when released by the key barrel or other contrivance. After the hammer or other contrivance has acted upon the bell or other instrument, the tumbler by coming in contact with a suitable surface or projection is moved into such a position that the rotating cam or other moving contrivance at the end of the lever will come in contact with the tumbler, and again move the lever, and set the hammer or other appliance in readiness.—Patent abandoned.

181 J. Edwards, Hackney. *Passengers and guards railway communications.* Dated January 20, 1869.

This consists in the application of a tube, rope, or wire, with elastic connections, to the carriages of a train, suspending a weight at the ends. This tube, rope, or wire is jointed where required, and in order to signal the guard it is only needful to break the joint and set the weights at liberty, and allow them to fall, causing a bell to ring. Also in placing a piece of paper with known characters on it over the part to be moved to give the signal, which paper must be torn before the signal can be given.—Patent abandoned.

182 E. Burton, Upper Clapton. *Sand distributing machine.* Dated January 20, 1869.

The inventor places a hopper of suitable size in a frame mounted on wheels to render it portable, the hopper serving to contain the sand or other material. A fluted roller is mounted in bearings transversely in the framing at the bottom of the hopper, so as to close the same. This roller, on being rotated by means of suitable gearing driven by one of the wheels of the machine, distributes the sand or other matters with which the hopper is filled evenly over the surface of the ground. He also provides a gate composed of a number of independent flaps hinged to the hopper, and kept up against the fluted roller by springs or other means, so as to allow of stones or other substances mixed with the sand passing through, and at same time prevent the too rapid delivery of the sand.—Patent completed.

183 E. Barcroft, Rawtenstall. *Cocks, taps, and valves.* Dated January 20, 1869.

Instead of the valve or plug, as now used, the inventor employs a cup inverted on a seating of leather. This cup has a shank or pin, which is received in a hole in the screw spindle of the top, the pressure raising the cup and admitting the flow of liquid. On the plug being screwed down the cup is bedded on its seating.—Patent abandoned.

184 P. C. Evans, Gloucester. *Apparatus for feeding wool.* Dated January 20, 1869.

This invention comprises automatic apparatus, whereby the wool is weighed in separate quantities and deposited at intervals upon the ordinary endless feed cloth, which carries it into the machine. The wool may be supplied to the weighing apparatus by any of the various kinds of feeding mechanism in use or proposed for feeding wool from a heap or bulk, but the delivering action of such mechanism must be stopped as each charge of the weighing apparatus is completed, to be re-started at intervals by a slowly-moving catch or stud actuated from the carding or other machine to which the apparatus is applied.—Patent completed.

185 M. J. Matthews, Glasgow. *Improved harmoniums.* Dated January 20, 1869.

A knee lever is applied in the ordinary position of such levers to be acted on by the knee and by suitable connections to open the swell valve or valves, but, instead of arranging this lever to be acted on in one direction only, it is contrived to act and open the valve or valves when it is pressed by the knee, either to the right or to the left. To obtain this action it is mounted on a vertical hinge and is formed with projections on both sides. There is a broad lever behind it, and to whichever side the knee lever is moved the projection on that side pushes back the bottom of the broad lever. A cord or wire is connected to the top of the broad lever and draws forward a wedge, which enters under and lifts a bar connected to the valve or valves, and so opens them.—Patent abandoned.

186 H. A. Bonneville, Sackville-street. *Making gas, &c.* (A communication.) Dated January 20, 1869.

This relates to a process for manufacturing illuminating gas in which hydrocarbon fluids, such as rosin, rosin oil, crude petroleum, waste vapours from oil wells, &c., are passed through a retort filled with metallic ore, heated to a red heat in such a manner that a portion of the surplus carbon contained in said hydrocarbon fluids will combine with the metal of the ore, while another portion thereof combines with the oxygen of the ore and passes off in the form of carbonic acid, the remainder of the hydrocarbon being converted into hydrogen or illuminating gas, and thereby a double object is accomplished, viz., the production of a permanent illuminating gas, and also the conversion of the ore into sponge of a superior quality, at a comparatively small cost.—Patent completed.

187 H. A. Bonneville, Piccadilly. *Pianofortes.* (A communication.) Dated January 20, 1869.

This consists in the arrangement of a metallic action frame or a metallic frame supporting the action of an upright or other pianoforte, which frame is secured directly to the wrest plank and composed of hangers or standards perforated with holes to receive metallic traverses in such a manner that the derangement of the action due to the expansion or contraction of the wooden rail generally used for supporting the action is avoided, and a firm unchangeable support for the several parts constituting the mechanism of the action is obtained. The invention consists, further, in the arrangement of flanged metallic rods or flanged metallic tubes filled with wood and forming traverses connecting the metallic hangers or standards of the action frame in such a manner that a firm and unchangeable connection for the hangers or standards, and also a convenient and safe support for the various parts constituting the mechanism of the action, is obtained.—Patent completed.

188 F. Lipscombe, Strand. *Purifying and storing water.* Dated January 20, 1869.

The inventor constructs a chamber in the lower part of the filter, through which, by means of an aperture, the unfiltered water flows finding an exit through another aperture to any convenient part or parts of the house or building when necessary. The top side of the chamber is perforated with holes through which the unfiltered water in the chamber flows upwards through the filtering media, which is composed of animal or vegetable charcoal, plates of porous stone, or any of the usual filtering media separately or in combination, whence the purified water is drawn off either directly through one or more pipes leading to the outside of the cistern, or the purified water after leaving the filter is allowed to flow into a pure water reservoir placed or formed in the cistern, whence it is drawn off as required.—Patent completed.

189 C. de Bergue and C. Faure, Strand. *Locomotives and railway carriages.* Dated January 20, 1869.

This consists in constructing bogey supported locomotives with cylinders fixed or carried on the boiler or trunk or frame which rests on a bogey, and with the cylinders driving the bogey wheels. Also in constructing locomotives bogey supported or otherwise with compound compensation couplings between the wheels or working parts, which by connecting rods between them are required to be driven one from the other. These couplings permit or give out the desired extent or fixed amount of motion to the wheel or part driven, although the length between the driving and the driven parts will somewhat vary, also the working the valve or valves of one cylinder of a locomotive from off the motion of the piston rod of the other cylinder, and *vice versa.*—Patent abandoned.

190 D. Spooner, Kilburn. *Mills for cleaning grain, &c.* Dated January 20, 1869.

This consists in employing in place of the ordinary single drum or roller a series of circular plates or discs arranged vertically at convenient distances apart upon an horizontal shaft and caused to revolve in connection with the same upon suitable bearings within the outer case or jacket of the mill through the medium of steam or other motive power, by the construction and arrangement of which the aforesaid additional rubbing and frictional surfaces are obtained and the grain thus operated upon in greater quantity and in less time.—Patent abandoned.

191 J. W. Wilson, Barnsley. *Steam boilers.* Dated January 21, 1869.

In an ordinary flue boiler the part over the fire the inventor makes the form of what is commonly known as the Butterley shape. The upper part of shell retains the same cylindrical form the entire length of boiler. A section of the under part of the shell at the firing end is raised up into the boiler to the same level as the top of the inner flue to which it is connected, thus forming an arch over the fire, and thereby affording considerable heating surface to the water over the arch and that in the space between the sides of the arch and outer shell.—Patent abandoned.

192 J. C. L. Camel, Lyons. *Truss.* Dated January 21, 1869.

The inventor employs a compressing bandage of caoutchouc or other material in a textile form or otherwise, and so shaped as to press upon the part to which it is to be applied. He attaches this compressing bandage to a small cylinder of wood or other material, between which and the bandage the part rests and is held in the required position. He attaches this apparatus to the person by means of such a system of bandages, straps, tapes, or ribbons, with or without buckles or elastic fastenings, as shall most conveniently fit the form of the patient.—Patent abandoned.

193 D. Rivenc, Geneva. *Apparatus for mending millstones.* Dated January 21, 1869.

The body of the apparatus is of cast iron, and is fixed (by means of screws attached to the driving shaft) on the surface of the stone to be cut. From the centre of the frame a cylindrical column rises, bearing at its lower end interiorly a socket, on which a second shaft passing through the first named turns. This latter shaft bears on its upper end two pulleys; the top one receives motion from a driving shaft, and the other transmits the necessary movement for cutting the stone. The upper part of the column has a movable support in cast iron, turning by means of a hollow cylinder or socket round the column which serves as an axis, with a ring fixed at will by means of a screw. The other end of the support bears the axis of a lever, having at one end two conducting pulleys receiving motion from the pulley by aid of a cord, and transmitting it directly to the "porte diamond" or cutting tool; the other end of the lever bears a movable counter balance acting as desired on the lever for regulating the tension of the cord.—Patent completed.

194 A. M. Clark, Chancery-lane. *Scarf clasps.* Dated January 21, 1869.

This consists of the clasp properly so called and a covering of silk or velvet material, which is caused to adhere thereto by gumming, sewing, riveting, or in other suitable manner. The clasp may be made separately, and coverings of different materials supplied with the same. Two modes may be adopted of fixing the covering to the

clasp foundation. For example, the foundation may be provided with small projections, which are turned down on the covering around its edges, or enter small openings made in said covering, or the latter may be provided with small projecting catches, which are caused to enter spaces made in the clasp.—Patent completed.

195 C. J. CHUBB, Tavistock-square, W.C. *Drills for boring coals.* Dated January 21, 1869.

The inventor employs a drill, the cutting end of which is formed with teeth to cut first into the coal an annular hole, leaving a cylindrical core standing in the centre. This core is afterwards broken up by other cutters or projections on the central portion of the end of the bar which forms the stem of the drill, which is twisted or formed into a screw to remove from the hole the pieces of coal.—Patent completed.

196 T. C. LEWIS, Brixton. *Steam engines.* Dated January 21, 1869.

This consists in the generation of as much steam as is necessary to give motion to the piston of the steam cylinder throughout one stroke, the operation being performed successively for the production of each stroke or each alternate stroke. The mode of producing the steam is by admitting a given quantity of water on to a highly heated surface of metal, by which means the water is immediately converted into steam and its pressure exerted on the piston.—Patent abandoned.

197 C. G. GUMPEL, Leicester-square. *Keyhole escutcheons.* Dated January 21, 1869.

A keyhole plate and escutcheon constructed according to this invention is as heretofore a plate of metal or other suitable material, provided with screw or pin holes or other means for securing it to the door, drawer, or other thing to which it is to be applied, but the keyhole in such plates has a small portion cut away or provision for allowing the escutcheon to be shifted out of the way clear of the keyhole, thus allowing play for a pin or connecting piece connected to the escutcheon, and also to a slide working at the back or inner surface of the keyhole plate, which surface has guides for such slide to work in.—Patent abandoned.

198 F. WALTON, Staines. *Artificial marble.* Dated January 21, 1869.

The inventor makes a framework or carriage running on wheels, which are covered with india-rubber or other soft material. These wheels run upon the extreme edge of the sheet of glass or other material on which the artificial marble is moulded. On this frame he fixes a metal gauge, which can be lowered to the face of the glass at pleasure by means of screws or levers. He also fixes on the frame a metal or glass roller, which can be lowered by the same means, and attached to this roller he fixes an anchor of steel to keep the same clean. He also places on this framework a hopper to contain a quantity of dry cement. This hopper is provided with a slot in the bottom of it, and above this slot he fixes a roller, and against this roller he adjusts by means of screws a gauge to regulate the quantity of cement to be supplied. The roller is made to revolve by being geared into the wheels which travel on the face of the glass, and from which the roller derives its motion. —Patent completed.

199 W. R. LAKE, Southampton-buildings. *Skim shearer.* Dated January 21, 1869.

This relates to a shearing apparatus wherein a lancet is employed, which may have a reciprocating rectilinear motion, a continuous circular motion, or a reciprocating circular motion. Each modification of this shearing apparatus has three distinct parts, namely, the comb, the lancet, and the counter knife. These three parts may vary in form, and the lancet may receive its motion by different means of transmission.—Patent completed.

200 R. BAXENDEN, Chorley. *Looms.* Dated January 22, 1869.

The pick made use of is what is usually called a metallic under pick, formed and worked in the following manner:—At the bottom end of the picking stick receiver is formed a ball joint, which gives a universal motion to the pick, the pick and plate at one end being toothed and slotted for setting or regulating the motion sooner or later as the loom may require; the other end of the plate is open for readiness in application.—Patent abandoned.

201 A. B. CUNNINGHAM, Military Academy, Woolwich. *Apparatus for veterinary purposes.* Dated January 22, 1869.

This apparatus is constructed with a flap or door fitted with a pad, and hinged or otherwise suitably attached at one side to the side of a frame fixed in the floor or paving, or to the floor or paving itself, so as to move up and down in a similar manner to that of a trap door. This frame is made of a size to receive the flap or door, and is let into a recess in the floor or paving so as to allow the flap to sit flush with the other part of the floor or paving. The flap or door is raised to a vertical position to admit of the horse (or other animal to be cast) being attached thereto by means of blocks and tackle, or other suitable means adjusted thereto, and communicating with pulleys fixed above on suitable supports.—Patent abandoned.

202 B. CRAIG, Branthwaite. *Signals for passengers guards, &c.* Dated January 22, 1869.

The inventor employs a simple cord or cords extending along the top of the carriages, and in communication at each end with a bell or other signal in the guard's van and on the engine. The cords between each carriage are united by spring clips. By the guard or driver pulling the cord, either can communicate with the other. The cord which runs along the roof of the carriage passes through an aperture made in a roller, which latter is supported in bearings, and at certain times free to revolve therein, motion being communicated thereto by a spring with ratchet wheel and pawl similar in construction to a spring blind roller.—Patent completed.

203 M. TILDESLEY, Willenhall. *Annealing cans.* Dated January 22, 1869.

This consists in making annealing cans used for the above-named purpose of cast iron of the description capable of being converted into malleable iron, and then annealing the cans, by which process of annealing the cans they are rendered much more durable, and are prevented from cracking or flying when subsequently submitted to the action of the fire for annealing purposes.—Patent completed.

204 J. WILKINS, Nottingham. *Looped and knitted fabrics.* Dated January 22, 1869.

Looped fabrics having a fleeced surface on one side or at the back thereof have been previously made with yarns or threads of various descriptions, but the yarns or threads employed were either plain or of one colour, or of threads of different colours. The present improvements consist in the employment of printed or parti-coloured yarns or threads in the production of the face on one side or surface of such fleeced, looped, or knitted fabrics, whereby novel and improved fabrics of the above description are produced, of superior appearance, and at less cost than heretofore in order to produce an equal appearance.—Patent completed.

205 J. SPEIGHT, Bradford. *Spinning and twisting machinery.* Dated January 22, 1869.

This consists in the application of a horizontal rotary shaft under each row or series in a line of the spindles, tubes, or bobbins. A series of discs or friction pulleys are mounted on the said shaft, and arranged so that by having a flange or collar formed on each spindle tube or bobbin, they will rest or be supported upon the said discs or pulleys, and by the frictional contact therewith receive rotary motion therefrom.—Patent abandoned.

206 A. MAW, Broseley. *Earthenware moulds.* Dated January 22, 1869.

From the original model either in clay or plaster the inventor takes a "box mould," by preference, in plaster of Paris. He proceeds as follows:—He places against the original model pieces of clay or other material, so as to divide it into segments after casting the first segment. He makes in the sides of the segment so cast notches or hemispherical indentations. In contact with this segment he casts the second segment, so that the pieces are kept in their proper relative position by means of corresponding projections and indentations, the process being repeated till the "box mould" is completed by a sufficient number of segments being cast round the original pattern or "block." After drying this mould (if of plaster) he applies a suitable material or solution to its whole surface to stop its absorption, for which purpose he either soaks it in a machine of wax and oil in a heated state, which he prefers, or in a solution of gelatine or other suitable material. Or, instead of using the original model, as above described, he employs a corresponding model of glue or gelatine in an elastic state, from which he casts a box mould in plaster or cement as above described in one piece, instead of in segments.—Patent completed.

207 F. R. ENSOR, Nottingham. *Ensor net machine.* Dated January 22, 1869.

The front warp thread always crosses from bobbin thread to bobbin thread behind the bobbin threads, and the back warp threads always cross from bobbin thread to bobbin thread in front of the bobbin threads. As the front warp thread from one bobbin thread crosses to the next bobbin thread its place is taken by the front warp thread. From this next bobbin thread which crosses to the first bobbin thread and similarly with the back warp threads on crossing from bobbin thread to bobbin thread, so that all the crossings in one longitudinal line of meshes are made by front warp threads, in the next longitudinal line of meshes they are made by back warp threads, then again in the next longitudinal line by front warp threads, and so on alternately.—Patent completed.

208 T. COOK and J. WATSON, Old Kent-road. *Gas measuring apparatus.* Dated January 22, 1869.

The inventors provide a closed chamber into which the steam, water, or other motive power is introduced by a suitable pipe. The top side of this chamber is provided with three or more passages for the exit of the steam or water, which passages or ports are placed in a circle and lead from the chamber in an inclined direction at any suitable angle, and open out beneath a wheel placed horizontally, and resting on top of the closed chamber. This wheel is mounted on a vertical axis, and its under surface is provided with a number of cells or recesses of suitable form and size formed near the circumference of the wheel. These cells when the wheel is rotated will pass successively over the inclined ports above mentioned, so that when steam or water under pressure is projected from the closed chamber through the inclined ports it will fill the cells contained in the wheel, and at the same time rotate the same by impinging on the sides of the cells.—Patent completed.

209 J. and J. HORSFIELD, Dewsbury. *Steam boilers.* Dated January 22, 1869.

Instead of making the two flues open from end to end, so that the products of combustion pass from the furnace directly into and through each of the flues, and thence into the other flues leading to the chimney, the inventors close the back end of the boiler and connect the rear ends of the flues inside the boiler by a cross flue or bend, so as to form a continuous cylindrical flue. They form behind the fire bridges of the two separate furnaces of the boiler a combustion chamber, into which each of the said furnaces opens. The continuous cylindrical flue hereinbefore referred to opens into and passes from the combustion chamber to the rear end of the boiler and thence back to the front part of the boiler immediately behind the combustion chamber. Here the flue joins a short vertical flue, the lower end of which opens into a longitudinal flue formed between the brickwork setting and the under part of the boiler. The rear end of this flue opens into a flue formed between the brickwork setting and the side of the boiler, which flue is connected by a cross flue under the front end of the boiler with a return flue on the opposite side of the boiler, which said flue passes to the rear end of the boiler and thence to the chimney.—Patent abandoned.

210 W. E. GEDGE, Wellington-street, Strand. *Slate quarry machines.* Dated January 22, 1869.

This movement of these machines takes place as follows:—When a rotary motion has been given to the tool holder by means of a lever fitted to it, a rod connected to and drawn by the lever comes against another lever which it causes to pivot, the result of this action being the uplifting of a driver resting on the toothed wheel of a windlass to which it gives a rotary motion. A chain fixed to the end of the tool holder, and passing over a pulley on the framing, winds on the above mentioned windlass or axletree, and thereby causes the tool holder to rise a certain regulated distance after each stroke of the cutter.—Patent completed.

211 W. DENNIS, Aldermanbury. *Letter-boxes, &c.* Dated January 22, 1869.

This invention consists in constructing the box with or without a fan wheel at the aperture and dividing the box at about the centre thereof with two pieces of metal of a triangular form somewhat similar to the letter V and either with or without a flap joint near the point thereof; the flap joint may be shut by a hinge and made to balance and close of itself, after a letter in its descent has pushed it open, and passed through into the bottom of the box.—Patent abandoned.

212 W. BURGESS, Newgate-street. *Mincing machines.* Dated January 22, 1869.

The inventor coats the interior surface of the casing with tin. For this purpose he first coats each of the two parts of the cast iron casing with zinc, by what is known as the galvanizing process, and as the parts of the case are taken out of the melted bath of zinc they are well shaken about to remove all superfluous zinc and to leave only a thin even coating upon the parts of the case. The parts of the case are afterwards cleaned with acid, by preference hydrochloric acid; they are dried and dipped quickly into a bath of melted tin, where they are allowed to remain only just so long as is required for the metal to take upon the surface. The articles are taken from the tin bath and shaken or by preference drained for a few moments in hot grease to remove the excess of metal.—Patent completed.

213 J. BEATTIE, Surbiton. *Buffing apparatus.* Dated January 22, 1869.

This consists in forming the sockets or guides in such a manner that they may serve as stuffing boxes, through which the buffer rods pass, and which can be adjusted from time to time when requisite, so as to prevent the lateral or vertical movement of the buffer rods. The inventor packs the recesses in the sockets with rope or cotton packing, or he uses india-rubber packing rings lined with metallic rings. He also forms on the base of the sockets one or more suitable projections (through the central one of which the buffer rod works), which he inserts into corresponding recesses formed in the carriage framing, and by these means the bolts which attach the sockets to the framing are relieved from lateral strain.—Patent completed.

214 J. MILWARD, Birmingham. *Sawing stone machinery.* Dated January 23, 1869.

A machine, constructed in accordance with this invention, in one of the simplest forms, viz., with one saw and two drills, has a plate or frame of a rectangular or other suitable shape, capable of being screwed by lewis bolts or other fastenings directly to the quarry face or attached to the engine or prime mover. A driving shaft (receiving a continuous rotary motion from an engine or other motor) is mounted at right angles with the frame in a bearing fixed in an opening in a central position in the frame, and the inner end projects on the front or acting side of the machine, and carries a crank, from which, by means of a connecting rod and slide, a reciprocating motion is imparted to the saw frame. The saw frame is composed of the blade or cutter bar for its lower side, the end bars and a top rod or bar having screws and nuts at the ends to tighten the blade in the usual way by means of an intermediate bar forming a fulcrum. It has in its upper division a central vertical rod, upon which is fitted a slide block, and this slide block is also fitted to work upon a horizontal rod attached to the face of the machine frame, and is connected by a rod of a length about equal to the crank connecting rod to the slide block of the crank motion, but sufficiently far out to be clear of the crank motion. In this arrangement the saw frame, when in the middle of its path, is about central with the crank shaft, and while receiving its reciprocating motion therefrom is free to descend as it cuts. The bearing of the crank shaft is made adjustable to a certain extent, so that the saw blade may be made to cut more or less on either side. The saw blade or cutter bar is furnished with a number of teeth of diamond or other very hard substance, the end ones being fixed at the lower corners of the ends of the blade which project somewhat beyond end bars of the frame. All the teeth may be arranged to cut the full width of the channel or the intermediate ones on alternate sides of the blade.—Patent completed.

215 J. ORTTON, Wandsworth-road. *Steam graduating machinery.* Dated January 23, 1869.

To a lever, called the reversing lever, the inventor attaches an additional lever, which he calls a graduator, supplied with a graduating quadrant and connected in such a manner with the reversing lever and its connecting rod that the smallest movement of the rod by means of the reversing lever can be subdivided into a lesser movement to any required degree by means of a graduator. When the reversing lever connecting rod is connected with the lower end of the reversing lever instead of at an intermediate point in its length, as in the before mentioned case he attaches a bell crank lever or graduator at the lower end. This graduator is attached at its centre to the lower end of the reversing lever, and at its two extremities respectively to the connecting rod and hand gear or graduating quadrant connection. In this case the movement of the handle is transmitted to the reversing rod by means of the bell crank lever, thus giving the same result.—Patent completed.

216 E. SIMONS, Sheffield. *Communication between passengers, &c.* Dated January 23, 1869.

Inside or outside the roof of each carriage, extending in a longitudinal direction from end to end thereof, is fixed a tube of metal, gutta-percha, or other suitable material. Inside each compartment is a small branch tube provided with a mouthpiece, and at each end of the carriage a piece of vulcanized india-rubber or other flexible and elastic tubing is connected to the longitudinal tube above mentioned, forming a continuation thereof, and provided with a screwed socket or other simple and rapid means of making a flexible and airtight join between the tubes when the carriages are connected together. On each side (before and behind) of each branch tube the main tube is provided with a valve or stop opening by means of a spring, but capable of being compressed and closed by means of a button or other simple contrivance, so that by closing one of these valves or stops and leaving the other open the passenger can communicate by means of the mouthpiece and tube in either direction—backwards to the guard or forwards to the engine-driver.—Patent abandoned.

217 W. HUGGINS, Halstead. *Millstone dressing.* Dated January 23, 1869.

This invention has special reference to dressing millstones by means of diamonds or other hard substances, and an important feature in this invention consists in making the "cracks" or "dress" of the stones in segments of a circle instead of in the usual rectilinear direction up or down the lands or grinding surfaces of the millstones. The "cracks" or "dress" may consist of a

series of continuous segmental curves from the eye or centre of the stone to the periphery, but two several concentric series of such curves may be used when thought desirable.—Patent completed.

218 L. CROSSLEY, Halifax. *Steaming printed yarns.* Dated January 23, 1869.

The inventor forms an outer shell or jacket, partly or entirely round the framework of the steam chamber as hitherto used, which framework thus furnishes the inner casing of the vessel, leaving a hollow space between for the introduction of the steam, and by this means, the inner casing being kept constantly at a great heat, the condensation of the steam when admitted within the inner portion of the chamber where the yarns are placed will be nearly or altogether obviated. The steam can either be admitted within the inner chamber direct from the space between this and the outer shell by means of a valve, or it may receive the steam direct from a pipe passing through the outer casing into the inner part of the vessel, without being first admitted to the hollow space between the two shells.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated August 10, 1869.

2383 E. A. Curley, Bartholomew-close, City. The better or more direct and effective application of reciprocating or intermittent motive power under certain circumstances, and which is especially applicable to lathes, sewing machines, velocipedes, and a great variety of manual and pedal apparatus.

2384 R. Longdon, Manchester. Improvements in safes and refrigerators for preserving and cooling food and other articles.

2385 T. Hancox, Sheffield. Improved machinery or apparatus for rolling metallic axles for wheels, and for rolling guns, shafts, or other circular articles in malleable iron or steel.

2386 C. Lockman, Hamilton, Wentworth, Ontario, Canada. Sewing cloth, being an improvement on sewing machines, which consists of a self-adjustable thread regulator, constructed so as to permit the sewing of cloth of different degrees of thickness without adjustment in changing from one to the other, to be known as Lockman's automatic thread regulator for sewing machines.

2387* E. T. Hughes, Chancery-lane. Improvements in the construction of rock boring machinery, and in air compressors for working the same, part of which improvements are applicable to other purposes.

2388 C. W. Zenger, C. L. Strube, and L. Merlett, Buckau, Prussia. A globular-cylinder manometer with double capillary lock.

2389 S. Hutchinson, Leeds. Improvements in machinery or apparatus for striking out leather.

2390 J. E. Holmes, Buckingham-street, Strand. Improvements in cutting and dressing stone.

2391 T. S. Blair, Tavistock Hotel, Covent Garden. Improvements in the manufacture of iron and steel.

2392 T. S. Blair, Tavistock Hotel, Covent Garden. Improvements in the treatment of conglomerates of cast iron and other substances, and in apparatus employed for that purpose.

2393 J. Caddick, Birmingham. Improvements in candlesticks, and in manufacturing parts of candlesticks.

2394 F. Mazet, Allees de Meilhan, Marseilles, France. An improved match box candlestick.

2395 S. J. Woodhouse, Holbeck, Leeds. Improved apparatus for purifying and regulating the supply of gas to burners, and also for an improved standard tap.

2396 W. Wright, Birmingham. Improvements in knobs and spindles.

2397 H. Bessemer, Queen-street-place, Cannon-street, City. Improvements in the methods and apparatus employed in the fusion of metals and metallic alloys, and in founding or casting the same.

2398 C. D. Watson, Liverpool. Improvements in waterproofing fabrics, and in the manufacture of compositions suitable for this purpose.

2399 A. H. Brandon, Rue Gaillon, Paris. Improvements in metallic cartridges.

Dated August 11, 1869.

2400 J. Tenwick, Spittlegate Ironworks, Grantham, Lincolnshire. Improvements in lubricators.

2401 A. B. Brown, Alfred-road, Birkenhead, Cheshire. Improvements in hydraulic printing or copying presses.

2402 J. B. Austin, Victoria Wharf, Earl-street, Blackfriars, City. Producing and applying black, white, or coloured and shaded patterns of needlework on vellum, cloth, paper, or other material, with perforations for displacing the same from the material, whether canvas, cotton, silk, satin, velvet, or other substances, on which they are worked.

2403 C. Crossley and B. Whipp, Manchester, and T. Crossley, Rochdale. Improvements in the manufacture of size.

2404 J. Cross and J. M'Cann, Farnworth. Improvements in the manufacture of dry soap for washing, cleansing, calendering, and finishing cotton and cotton fabrics, wool and woollen fabrics, and mixtures of the same

2405 G. White, Queen-street, Cheapside, City. Improvements in pipes for smoking tobacco.

2406 F. H. Needham, Mortlake, Surrey. An improved apparatus to be applied to casks or other vessels containing liquid, to preserve the liquid while on draught.

2407 J. Mayer, Brooklyn, New York, U.S.A. An improvement in hoop skirts.

2408 A. M. Clark, Chancery-lane. Improvements in the manufacture of phosphate of ammonia.

2409 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of iron and steel.

Dated August 12, 1869.

2410 J. F. E. Martin and L. G. Le Quay, Randan, France. An improved construction of submarine and other tunnels.

2411 W. Davis, Great Yarmouth, Norfolk. Improvements in machinery or apparatus for stamping, crushing, and grinding ores and such like substances.

2412 J. Parrish, Bolton, Lancashire. Improvements in the construction of skips, hampers, and other baskets.

2413 D. Barker, Northfleet, Kent. Improvements in the manufacture of artificial fuel.

2414 W. E. Newton, Chancery-lane. Improvements in centrifugal pumps.

2415 J. Deas, Glasgow, and R. C. Rapier, Westminster Chambers, Westminster. Improvements in lifting jacks for lifting railway rails.

2416 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for charging gas retorts.

Dated August 13, 1869.

2417 H. Hudson, Oaks-crescent, Wolverhampton. An improved apparatus for effecting communication between railway passengers, guards, and engine drivers.

2418 D. A. Gibbs, Milton-street, City. Improvements in compositions for coating or covering the sides and bottoms of ships and vessels.

2419 E. J. Grabham, Shepherdess-walk, Middlesex. Improvements in machinery or apparatus for plaiting or folding textile fabrics, paper, and other like materials.

2420 O. E. Brooman, Fleet-street. Improvements in treating the waste of wool, silk, horn, and other nitrogenized animal matters to be used as manure. (A communication.)

2421 E. J. Hill, Victoria Station, Pimlico, and R. Davis, Craven-street, Strand. An improved signalling apparatus used in hand signal lamps.

2422 T. Beckwith, Stockton-on-Tees. Improvements in reaping and mowing machines.

2423 L. E. Woolf, New Bond-street. Improvements in castors.

2424 J. Cowan, Barnes, Surrey. Improvements in the manufacture of soap.

2425 J. Lewis, Fenwick-street, Liverpool. Improvements in extracting copper from its ores.

2426 J. Hampton, Wednesbury, and S. Partridge, Darlaston, Staffordshire. Improvements in velocipedes.

2427 W. Richards, Birmingham. Improvements in breech-loading firearms and in cartridges to be used therewith.

Dated August 14, 1869.

2428 T. Sagar and T. Richmond, Burnley, Lancashire. Certain improvements in looms for weaving.

2429 J. Kenyon, Blackburn, Lancashire. Improvements in apparatus for consuming smoke and saving fuel.

2430 L. D. Newall, Chancery-lane. Improved apparatus for diminishing the effects of the oscillation of vessels and for preventing sea sickness.

2431 W. Matt, Homerton, Middlesex. An improved compound or composition in imitation of marble, veneer, and other substances, to be used in the manufacture of fancy and other articles.

2432 H. T. Yates, Nottingham. Improvements in the manufacture or production of cops and spoles.

2433 T. Coad, Truro, Cornwall. Improvements in the construction of sewing machines.

2434 S. Smith, Halesworth, Suffolk. Improvements in common road carriages.

2435 E. H. C. Monckton, Threadneedle-street. Improvements in agricultural machinery and in appliances for harvesting and preserving crops.

2436 J. B. Rushbrook, St. Andrew's-street North, Bury St. Edmund's, Suffolk. An improved hurdle for folds for lambs and sheep.

2437 G. Ash, Great Marlborough-street. An improved denture or appliance for carrying and supporting artificial teeth in the mouth by suction.

Dated August 16, 1869.

2438 T. Ward and W. S. Black, King's Lynn. Improvements in machinery for twisting tobacco.

2439 J. Mitchell, Bradford, Yorkshire. Improvements in kilns for burning bricks, lime, and articles of earthenware.

2440 H. Pinkus, Camden-road, Camden Town. Improvements in furnaces and other heating apparatus, and in the methods of applying and using therewith certain elements of combustion, and in the combinations therewith of the processes with materials to be used in the manufacture of metals and other things and uses, and in the mechanical constructions necessary therefor.

2441 J. Blyde, Sheffield. Improvements in scissors or apparatus especially suitable for gathering flowers and fruit.

2442 H. Dupland, Boulevard Bonne-Nouvelle, Paris. A system of coatings against dampness and saltpetre.

2443 J. G. Dale and E. Milner, Warrington, Lancashire. An improved method of producing white pigments from lead.

2444 G. Sunderland R. J. Midgley, Halifax, Yorkshire. Improvements in machinery or apparatus for spinning and doubling or twisting worsted, silk, or other fibrous substances.

2445 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in the process of charging and discharging fuel in gas retorts or other gas distilling apparatus.

2446 H. H. Trenor, New York. An automatic passenger register or apparatus for recording the number of individuals entering any place or vehicle or passing over such apparatus.

2447 S. Harvey, Dale-road, Haverstock Hill, Middlesex. Improvements in apparatus for indicating signals between passengers and guards in railway trains.

2448 F. Ransome, Queen-street-place, City. Improvements in the manufacture of artificial stone.

2449 J. Lawson and E. G. Fitton, Leeds. Improvements in spinning flax, hemp, jute, and tow, and in machinery for these purposes.

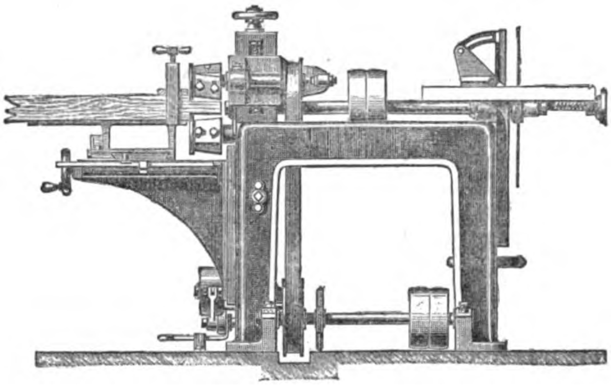
A. RANSOME AND CO.'S
NEW PATENT "GENERAL JOINER."

(PATENT DATED FEBRUARY 17, 1869.)



PATENT GENERAL JOINER AS ARRANGED FOR RIPPING-OUT AND TENONING.

In introducing their new Patent General Joiner to the public, A. Ransome and Co. describe briefly a few capabilities of this most useful machine, viz. :—

SAWING. It will Work Saws up to 20in. in diameter, and saw stuff up to 7in. thick.

CROSS-CUTTING. It will Cross-cut wood of any length, up to 4in. thick.

PLANING. It will Plane both sides and Thickness, in one operation, boards up to 7in. wide.

MOULDING. It will cut single or double mouldings of any pattern, in any kind of wood, up to 5in. wide.

GROOVING. It will cut grooves from $\frac{1}{8}$in. to $1\frac{1}{2}$in. in width.

TENONING. It will make perfect Planed Tenons in one operation.

MORTISING. It will make Mortises from $\frac{1}{8}$in. to 2in., of any length, in any kind of timber.

BORING. It will Bore Holes from $\frac{1}{8}$in. to 2in. diameter.

In addition to the above, A. R. and Co.'s Patent General Joiner may be used for Rebating and Moulding Sash Frames, &c., Mitreing, Chamfering, Tongueing, Beading, and a great variety of other purposes. It is worked by two lads, and will do the work of at least *thirty skilled joiners.*

IT POSSESSES THE FOLLOWING ADVANTAGES OVER OTHER MACHINES OF THIS CLASS :—

1.—The Tenoning, Planing and Thicknessing, and Moulding operations can be carried on without interfering in any way with those that are done at the Sawing end of the Machine, such as Ripping-out, Cross-cutting, Squaring-up, Tongueing, Grooving, &c.

2.—The Tenons are formed at one operation by *cutters*, which finish them much more accurately than is the case where saws are employed for this purpose, as in other machines of this class.

3.—The wood to be Tenoned, which may consist of several pieces up to a total width of 18in., is cramped in a horizontal position upon a light sliding plate, instead of each piece being fixed separately in a vertical position, as is the case in other General Joiners.

4.—Tenons can be formed with shoulders of unequal lengths, by simply altering the position of one of the Tenoning blocks on its spindle.

5.—It will plane both sides at once, and thickness boards up to 7in. wide, and will cut single or double mouldings of any pattern in any kind of wood. In other machines of this class one side only can be planed at a time.

6.—The wood being planed is fed through by *a pair* of revolving feed rollers, *both of which are driven*, by which means a greatly increased propelling power is obtained, and the rollers being perfectly smooth, do not indent the wood. This advantage cannot be overrated, as the injury done to boards by the grooved roller used in other machines is very considerable.

7.—The top feed roller rises and falls to suit the irregularities in a rough board, and, at the same time it is always exerting its full feeding power. The rate of feed can also be varied from 5 to 12ft. per minute, whilst the machine is in full work, and the lad working at this portion of the machine can retard or accelerate the feed, according to the nature of the wood about to pass under the cutters.

8.—Ins tead of the long and cumbrous fence, which in other "General Joiners" is required to carry the tenoning slide, a light fence is substituted, which is arranged to turn over and hang down below the table, thus enabling the machine to be used as a Cross-cut Saw Bench for any length of stuff without interfering with the work going on at the other end of the machine. In other Joiners this is impracticable on account of the difficulty in removing the fence.

In addition to the advantages described above, and which alone would render this Machine far superior to any other of its class, A. Ransome and Co. guarantee their Patent General Joiner to be fully as effective in performing all the other operations usually done by General Joiners.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, AUGUST 27, 1869.

THE AIR OF MANUFACTURING TOWNS.

IN these days a reputation can be cheaply and easily made by abusing the water supplies of various towns. The materials required by a popular writer are all found for him, and he has only to make the utmost of the "impurities" by multiplying them into sufficiently large amounts to strike terror into the minds of his readers. The air we breathe has not yet received so much attention. It is more difficult of examination, and there is no chance of getting up an agitation for placing the supply in other hands. So quacks have little to work upon, and interested agitators have nothing to work for. If, however, it were asked which is of the greater importance, pure air or pure water, there is no one, we believe, who would not reply without hesitation, pure air. The amount of water which even an enthusiastic teetotaller drinks is very small, and the quality of that he washes in, and which goes down his closets, is of little consequence. But a man must breathe and take into his lungs thirty or forty gallons of air a day, and surely it is of the first importance that the very source of life should be kept as pure as possible. Few restrictions, it may be said, have been put on the direct pollution of the atmosphere. Black smoke is an offence at law, but local boards, who set the law in action against black smoke, allow untrapped drains in every street, and so permit the far more dangerous emanations from the sewers to poison the atmosphere all over London.

But it is not with London that we are now concerned. We have before us the fifth report of the inspector of alkali works, which gives us an account of the state of the atmosphere in some of our centres of industry. Perhaps the best information we can get as to the condition of the air of any particular locality is afforded by an examination of the rain water which falls on the spot. In this we shall find all the impurities which water can wash from the atmosphere, and the dirt of the air is found in the water-butt, just as the dirt of the clothes is left in the wash-tub. When rain water therefore is examined a variety of impurities are discovered, the amount of which it may be said at once mainly depend upon the quantity of coal consumed in the locality. The first in amount is sulphuric acid, which is partly free and partly combined with ammonia, and it may be with soda. Rain water caught close to some chemical works gave Dr. Smith 5 grains of sulphuric acid in the gallon; the rain at Liverpool yielded 2½ grains; at Newcastle-on-Tyne, 3 grains; at Manchester, 3¼ grains. Much of this acid must be free, for we are told that rain water at Manchester always reddens test paper. But besides sulphuric, rain always contains some hydrochloric acid. The proportion of this acid is much greater in the "pure" air of the seaside, and is obviously derived from the common salt which is carried up from the sea. Of course, the quantity of sulphuric acid sent into the air depends upon the quantity present in the coal. The coal of South Lancashire contains an average of 1·37 per cent. of sulphur, and Staffordshire coal still more. "Smoke from such coal," Dr. Smith says, "is injurious to plants," and if to plants, surely to animals also. It is worth noting here that Dr. Smith, who examined the air of Manchester in 1851, finds a much larger quantity of sulphuric now than he did then.

Besides the acids mentioned ammonia is found in rain water. Most of this is also produced by the combustion of coal, but some must be the products of animal and vegetable decomposition. Rain caught in Manchester in December, 1868, had about 100 grains of ammonia in the ton. Newcastle rain contained about as much, Glasgow a little less, and rain caught in London in February of this year had about half the quantity. Other matters found in rain water we must dismiss very briefly, though they are not the least important. When rain is evaporated, and the solid residue is burnt, it smells of substances which have but one origin, the decomposition of animal matter. They are sewage matters in fact, and often the most virulent of all poisons; and in the last outbreak of cholera in Holland the disease was almost as fatal to those who drank rain as to those who used the foulest drain water.

The examination of rain gives us, however, no idea of the proportion of the impurities to the bulk of air. To ascertain this, measured quantities were washed with pure water. The measurements of air, we are told, are not to be relied upon as perfectly exact, so we must accept the results as only approximate. With this reserve we may say that about a million cubic feet of air in Manchester on a fine November morning contained 4,008 grains of sulphuric and 59 grains of hydrochloric acid. At St. Helens also on a fine day about the same quantity of air contained 2,293 grains of sulphuric and 199 grains of hydrochloric acid. The large quantity of hydrochloric acid found in this latter place is owing to the number of alkali and glass works on the spot. In contrast to these we may place the air of the Lancashire watering place Blackpool, in which, assuming the same measurement, only 20 grains of hydrochloric and 155 grains of sulphuric acid were found.

We have only space to allude shortly to smoke. Black smoke everyone knows to be a nuisance and a waste, and Dr. Smith clearly shows us the reason. He obtained permission to make some black smoke in Manchester, and submitted it to analysis. Putting the analyses together we may say that 100 cubic feet of black smoke contained 900 grains of water, 18¼ grains of soot, and 33½ grains of sulphurous acid. The soot in this analysis only represents a portion of the waste, for among the gases to be found in black smoke are carbonic oxide, olefiant gas, and occasionally marsh gas and other hydrocarbons, the products of the distillation rather than the combustion of coal. The proportion of oxygen found in the smoke proves that it is not from want of air that the smoke is not burnt. Too great draught is indeed the cause; and patentees, who nearly all, says Dr. Smith, have confined themselves to the supply of air, must turn their thoughts in another direction.

On another occasion we may call attention to one or two other matters mentioned or suggested by this report, but at present we must conclude by saying that, as regards the Alkali Act, it is clearly shown to be working with the utmost success; but the report at the same time makes it equally clear that the atmosphere is enormously polluted from other sources than alkali works.

STEAM CRANE BOILERS.

THE increasing number of boilers used for steam crane and other similar portable purposes renders it important that any dangerous defects to which these boilers are liable should be generally known. The explosion of these boilers has become by no means unfrequent; and, as they are now constantly used in the erection of public buildings, and sometimes in close proximity to crowded thoroughfares, the subject becomes of increasing importance. We, therefore, take the present opportunity of placing before our readers a few points in connection with this class of boilers which are referred to by Mr. Fletcher in a recent report to the Manchester Steam Users' Association. The boiler to which reference was specially made was of the internally-fired vertical class, cylindrical in the external casing, as well as in the internal firebox, and domed on the top, while the flames from the firebox passed off to the chimney through a single central uptake tube, which formed a most important tie between the crown of the firebox and that of the external casing. Boilers of this type are very simple in construction, and well calculated, when new, to resist a high pressure, so that they are very generally adopted. The dimensions of the one under consideration were—height, 8ft. 9in.; diameter, 3ft. 6in. in the external shell and 2ft. 9in. in the firebox, while the thickness of the plates was 5-16in., and the load on the safety valve per square inch 70lb. In this boiler there was found a deep groove or furrow running entirely round the inner casing of the firebox at the bottom of the water space, and eating into the metal to a depth varying from 1-8in. to 3-16in., so that more than half the strength of the plate was gone. This is not a peculiar case; others very similar have been met with, and especial danger arises from the fact that these grooves are very difficult to detect. They take place so low in the water space as to be very nearly, if not entirely, concealed by the blocking ring at the bottom, while the only opportunity of examining them is through one or two small sight holes cut through the outer casing.

It is frequently supposed that because boilers are small therefore they are safe, whereas the fact of their being small makes them dangerous. Small boilers cannot be inspected as larger ones can, since they do not admit of access for a man, and, therefore, they are to a greater or less extent apt to be worked on at a risk. The internal examination of portable boilers, so important to their safety, is a question which hitherto has not received that consideration which it deserves, but the subject should no longer be neglected. It is well worthy of the attention of engineers to endeavour to construct such portable boilers as are too small to admit of a man's getting inside so that they may be taken to pieces for examination, and it becomes imperative either that arrangements should be made for doing this, or that these boilers should not be allowed to work on for more than three or five years without being cut open for examination, whatever the inconvenience might be. No doubt, if the attention of engineers were directed to this subject inventive talent would soon construct boilers that could without much difficulty be taken to pieces so as to be examined internally, and thus their safety ensured.

HYDROSTATIC STEERING APPARATUS OF H.M.S. "ACHILLES."

IN our impression for the 6th instant we inserted a letter from Rear-Admiral Inglefield upon the subject of steering gear. This letter contained a reference to the gallant Admiral's own labours in improving this class of machinery. It has attracted considerable attention, and we have been requested to publish further particulars of the Admiral's invention, which we now have much pleasure in doing. We may premise that in designing this apparatus Admiral Inglefield has taken advantage of that great natural power which every floating vessel carries with it, viz., the hydrostatic pressure of the water which sustains it. He thus has at his command an agent ready to be brought into action at a moment's notice. In such a vessel as H.M.S. "Achilles" the pressure of the external water amounts to a load of about 8lb. per square inch at the level of the work-

ing cylinder, viz., on the floor of the screw alley or the tunnel through which the screw shaft is conducted to the stern of the vessel. To move such a mass as the rudder of the "Achilles" against the resistance of the water when the vessel is going at 14 knots per hour requires very considerable power, and the problem to be solved was how to utilise the constant pressure of 8lb. per square inch, magnifying it so as to obtain sufficient force to overcome the resistance of the rudder. We will describe the manner in which this is effected by the Admiral, remarking that similar machinery may be adapted to any vessel.

A large cylinder, fitted with a piston and slide valve like that of a steam engine, is fixed horizontally in the lowest available part of the vessel. The external water is admitted to this cylinder through a Kingston valve guarded by a sluice valve. A powerful water engine is thus formed ready to be set in action as occasion may require. Special arrangements for working the slide valve with unfailing certainty have been applied. A barrel is fixed at each end of the cylinder, and the piston rod extending on either side of the piston works in these barrels, which thus form powerful hydraulic pumps. These pumps are connected by pipes with two hydraulic cylinders fixed one on either side of the tiller on the lower deck. The rams of these cylinders are connected together by a crosshead carrying a strong steel pin entering a block, which slides in a groove attached to the under side of the tiller. Thus the tiller can traverse its full arc in either direction, while the rams move rectilinearly to and fro. The water in its course from the hydraulic pumps to the tiller cylinders passes through a valve box fitted with a regulating or directing slide. This slide is worked by a rod extending upwards to the wheel house on deck, and passing downwards to wheels on the lower decks, one of which may be on the screw alley far below the water line. The wheels are worked by hand like an ordinary steering wheel, one man moving them with ease. When the wheel is in its middle position the water is cut off from the pumps, but the two tiller cylinders communicate freely; thus the rudder is left free to right itself. By turning the wheel through one third of a revolution either way the water pressure is turned on to one or other of the tiller cylinders, and the rudder is put hard over to port or starboard as may be required. When the wheel is turned only half its stroke in either direction the water is locked in the tiller cylinders, and thus the rudder is held fast in the position to which it had been brought.

It will thus be seen that one man at either of the steering wheels does what it requires generally twenty-five men to do at the ordinary steering wheel. By means of the sliding block, acted on by a hand screw on the tiller, the hydraulic apparatus can be disconnected in less than a minute, and the tiller can thus be left free to be worked in the ordinary way; but this is not necessary, for by putting the directing slide in its middle position the tiller is left quite free, and can be worked by the ordinary steering wheels and tackle, which need never be disconnected. Thus the hydraulic steering gear may either act independently or it may be employed as a force auxiliary to the men without in any way interfering with the normal condition of the steering apparatus. It may be readily understood from the construction that the working power acts only when it is wanted. When the rudder has to be moved the hydrostatic cylinder or water engine acts; when the rudder is fixed in any position the water engine ceases to move, but remains ready to start into action the moment it is required with its full force. Our readers will now understand the general construction of the apparatus which has been found so successful in H.M.S. "Achilles." We need scarcely say that there were numerous details of construction which required great consideration in applying it. The whole apparatus, however, is extremely simple, easy of application, and not liable to derangement from accident or wear. We understand that it is cheaper than any other mechanical steering apparatus yet tried. The power which it utilises costs nothing, and is always ready to hand for use. These points, taken in conjunction with its success in the "Achilles," should be the means of opening the eyes of the Admiralty authorities to its value.

A MATHEMATICAL PIE.

It is well known that the negro mind works arithmetical calculations upon a different principle to that usually followed by the more favoured white men and brethren. Arithmetic, it is true, is called a science, but in reality, it is scarcely deserving the title. It is, in fact, a knack, which is partly intuitive and partly acquired, and the reverence for its possessor has completely died out. A "calculating boy" is regarded now more in the light of an intelligent juggler—a mental prestidigitateur—than a person to constitute a good engineer. We do not go so far as to assume that Mr. James Smith, in the volume now before us,* works out his unique value for π upon the principle of the negro mind, for in that case we might be considered to accuse him of being a follower of the "black art," but we are sorely afraid that from arguing so energetically about circles, he has ended by arguing in a circle. The transition is natural and effected with facility, more especially when it is borne in mind that our author is a willing sojourner in the mathematical labyrinth of his own creation. What a pity it is that we cannot have a whole without its part, or, to speak more scientifically, that an integral number should be capable of subdivision into fractional portions. There is no question but what Mr. James Smith proceeds upon sound data. The rule in science, as well as in ordinary mundane affairs, is to proceed from the complex to the simple. Look at our first attempts at engines and machinery. One single specimen possessed a greater number of component parts and complicated details, than half-a-dozen of the same species produced in more modern times. So it is with the received value of the Greek "Pi," usually symbolized by the letter π. "Recognized mathematicians," to use our author's term. and, indeed, all mathematicians, in their calculations take π equal to 3·141592, and as many more decimals of the right figures as you may choose to employ. In all practical estimates, the fraction 22-7 is a very neat value to use. An eminent mathematician has calculated the exact value of π to—we are afraid to say how many places of decimals, but of course he never arrived at it. But our author has. Oh! yes. He assumes, as a man should do under similar circumstances, that we are all wrong; we are the persons, *quibus lumen ademptum*. In fact, Mr. Smith is a mathematical radical of the first water. He not only will not allow this unfortunate "pie" to have the infinite number of decimal parts that have belonged to it from time immemorial, but he actually denudes it of the twenty-four that the choral traditions of the nursery have allotted to it, we may say, also from time immemorial.

In the cause of arithmetical inquiry and that thirst for mathematical investigation which, it is to be hoped, will always prevail among our students and elderly gentlemen, we do not for a moment deny our author the right to examine for himself into the contents of any scientific comestible. It is, however, just possible that ancient gentlemen rejoicing in sonorous and classically sounding names, such, for example, as Archimedes, might object were they able, poor souls, to a member of posterity, *cui nomen est* Smith, having a finger in their Greek pie, more especially when his object is to dock it of its fair proportions. After confounding premises and conclusions in a manner that would drive a logician to the confines of insanity, our author infers, deduces, concludes, and reinfers that the proper number of component parts to be allowed to the article in question is three and one-eighth, or, expressing it algebraically, $\pi = 3·125$.

Although we admire the disinterested manner in which Mr. Smith has given his invention to the world, we almost regret he has not kept it to himself. Just imagine how useless all our recognized tables for shortening the labour of calculation have become. All our ratios of areas, circumferences, diameters, and other circular functions must be recalculated. Our whole arithmetical system is upset. It is worse than the adoption of the decimal currency, or the revision of the Bible.

After perusing the treatise under notice, and balancing up the pros and cons of the arguments and controversial statements included therein, we are strongly of opinion that if the gentleman who finds "Euclid at fault" and cannot agree with the late talented author of "Quaternions" were to eat a little humble pie, he would perhaps be able to arrive at a more accurate knowledge of the Greek "Pi."

* The Geometry of the Circle and Mathematics as applied to Geometry by Mathematicians shown to be a Mockery, Delusion, and a Snare. Letter to G. C. Stokes, Esq., M.A., F.R.S., D.C.L., President Elect of the British Association for the Advancement of Science, 1869-70. By James Smith, Esq., Member of the Mersey Docks and Harbour Board, Ex-Chairman of the Liverpool Local Marine Board. Liverpool: Edward Howell, Church-street. London: Simpkin, Marshall, and Co., Stationers' Hall-court. 1869.

MR. MACFIE ON THE ABOLITION OF PATENTS.

In common, we presume, with most of the scientific periodicals of the day, we have received a copy of Mr. Macfie's compilation upon the abolition of patents. A glance at the heterogeneous mass of spasmodic matter forming its contents served to show us its importance, and we at once placed it at the bottom of a few books which are awaiting review on our table. Our purpose was to have noticed the volume with our next batch, inasmuch as we notice every book sent for that purpose, although a very few lines would have sufficed for it. But as we have found in the "Engineer" a critical review of Mr. Macfie's production, we shall for once allow another paper to discuss the book for us in our own pages. We need hardly state that a second inspection of the book enables us to endorse fully the opinions expressed in the notice in our contemporary, which runs as follows:—

The degree of influence Mr. Macfie may have reached amongst his constituents, and the weight attached to his speech in the House of Commons, we, of course, do not know. It is with the honourable gentleman as an author that we have now to do, and we congratulate him on having composed a remarkable book: composed, not written, seeing that the scissors and paste-pot have so largely contributed to the portly volume now before us. When Mr. Macfie does condescend to original composition, the liberties he takes with Queen's English are, for audacity at least, equal to his lucubrations; and, as if this were not enough, the hon. member must needs insult our gracious sovereign by writing her down as of the neuter gender. "The sovereign voluntarily puts itself," writes Mr. Macfie at p. 74 of this last contribution to patent literature. Very generously, the author informs his readers that "no rights are reserved." This is at least consistent, emanating as it does from one who gives his readers to understand, by quotations and otherwise throughout his book, that copyright, no more than patent law protection, commends itself to his free trade appreciation.

Bad as the volume before us may be, and is, it would be impossible to compose 332 octavo pages even on the scissors and paste-pot system, without contributing to the field of thought one or more leading ideas. Mr. Macfie's leading idea our readers already know. He denies that invention is property further than the law makes it property; and, on that ground of abstract ratiocination, he denies to inventors any sort of moral proprietary right. Still, for peace and quietness' sake—also, perhaps, to illustrate what kindly benevolence is hidden in capitalists' money bags—he would give honoraria to inventors of important things, varying in amount from £10,000, as a possible maximum, to a certificate of honour at the other end of the scale. To this purpose he would see £200,000 allocated yearly by Parliament; the sum to be raised as a general tax and distributed by some immaculate commission. From this prospective arrangement it would follow that—the sum being fixed, whilst the field of invention is infinite—candidates for honoraria must be prepared for diminution of reward according to scale, in any particular year when inventors might crowd most thickly. The hon. member is equal to the emergency. Under these circumstances, he hints that the Crown might distribute orders and ribbons. Why did he not add babies' coral, gum rubbers, rattles, and penny whistles?

The analogies of copyright have ever been a stumbling block to gentlemen who take a view of patent matters identical with Mr. Macfie. If it be not consonant with justice, and for the common weal, that proprietary rights in an idea should be secured to the first elaborator to working practice, in things mechanical and chemical, through letters patent or their equivalents—then how can it be consonant with justice and common weal that the same should be conferred on the elaborators of ideas into books? Gentlemen of Mr. Macfie's way of thinking endeavour to establish a radical difference in this manner, viz.—that whereas no conceivable book could be composed in its identity by two authors, one and the same invention may come out simultaneously under the auspices of different inventors. Those who put this distinction most prominently forward are not least unaware of the weakness of their case; and thus we commonly see they would abolish copyright also if they dared. Mr. Macfie is unable to veil under the sophistry of Scotch metaphysics run mad—a sophistry further obscured by bad English—that he at least is no friend to copyright. Mr. Macfie is welcome to any opinion on this topic that he may hold, for any influence he may command, or harm he may do. So long as peers and members of Parliament and other men influential in the land, write books, we shall be under no apprehension for the maintenance of some law of copyright sufficiently protective of that property. As to invention and inventors, the social conditions differ; and thus we find a crusade in which "money bags against brains," to quote an expression of John Stuart Mill, may go in for a small tilting match, great folks tranquilly looking on to see what may come of it. What strikes us most forcibly, in considering the debates initiated by Sir William Armstrong, and continued by Mr. Macfie, is the social audacity of the movement. The fact must be only too evident to every thinking man who has dispassionately viewed the aspects of social matters, and speculated on their issues, that the question, what is property, is one concerning which the million—the mass—may come to agitate in a way not favourable to existing conditions. Mr. Macfie tells us that invention is only made property by the operation of law—the same he affirms of copyright. Will he have the goodness to explain in what other way—through what different operation—land is made property? For our part, we confess inability to perceive, and men who have brains enough to make inventions will be equally unable with ourselves. Before the hon. member next takes scissors and paste-pot in hand, we advise him to reflect on this matter. Having done us the honour to reproduce one of our own articles bodily, we fear—were we to give him permission to do the same by this—his appropriative faculty might cease to experience a charm, for the reason that actuated a certain French lady, who regretted that eating an ice was not sinful, because—then—it would be so much more nice!

One word in conclusion. The price of this book is five shillings, postage fivepence. On the outside cover the author gives this to be understood Every representative book is good in a way. Mr. Macfie's comes under this denomination. As the worst specimen of book making we ever saw, on any subject, by any person—man or woman—it is a curiosity worth having. If a prize were offered for the production of a worse book the compiler might labour in vain.

PROCEEDINGS OF THE BRITISH ASSOCIATION.

THE British Association has just concluded its thirty-ninth annual meeting, under the presidency of Professor Stokes, an abstract of whose inaugural address appeared in our last number. We now proceed to give our usual report of the papers read, classifying them under the several sectional heads. We shall for the most part give only abstracts of these papers, but in some instances, where papers of special interest to our engineering readers are read, we shall supplement the abstract by the paper, *in extenso*, in a future number. At the meeting of the General Committee Mr. J. P. Gassiot, F.R.S., read the heads of the report of the Kew Committee for 1868-9. The first part of the report was divided into two portions, the first having reference to work done by the Kew Observatory under the direction of the British Association, and the second to work done at Kew as the Central Observatory of the Meteorological Committee. It is part of the business under the first head to verify barometers and thermometers; during the year 157 barometers and 1,153 thermometers had been verified. The attention of meteorologists was directed towards an instrument devised by Mr. Beckley, mechanical assistant at Kew, for the purpose of registering the rainfall automatically. An illustrated description of this instrument appeared in the MECHANICS' MAGAZINE for July 9 last. The last paragraph of the report is as follows:—In conclusion, the Kew Committee desire to bring under the notice of the British Association that the system of automatic records established and in actual work at the Kew Observatory comprehends magnetic, barometric, and thermometric observations, as well as those of the direction and velocity of the wind, to which an electric self-recording instrument will soon be added. They think that it would be very advantageous to magnetical and meteorological science if a fully illustrated work were published descriptive of these instruments, and of the method of working them, together with the method of reductions actually employed.

From the Kew balance sheet it appeared that the total expenses for the year were £1,178 7s. 11d., of which the Association supplied £600, and the rest was made up of allowances from the Meteorological Office and from various items of income such as charges for verification of instruments, &c. In the appendix were a description of the means adopted by the Meteorological Committee for ensuring accuracy in the numerical values obtained from their self-recording instruments, with tables, a code of regulations adopted by the Meteorological Committee for ensuring accuracy in the results derived from their self-recording instruments, &c.

The report was adopted.

A meeting of the General Committee was held in the Albert Memorial Museum on Monday afternoon, the President, Professor Stokes, in the chair. The object of the meeting was to determine the place of meeting for next year, and to nominate a president.

Mr. Griffith, the Assistant-General Secretary, read the invitations received from Edinburgh, Liverpool, Brighton, and Bradford, to hold the meeting for 1870 in those respective towns.

Mr. Drake proposed, and Mr. Freeland seconded, that Brighton's invitation should be accepted.

Upon being put to the vote, only 14 hands were held up for Brighton, and a large number against, and the President declared that Brighton was lost. Upon the hands being held up for Edinburgh and Liverpool, the numbers were so near that the President said he could not decide with any certainty. A division was then taken, after which the President announced that the numbers were—Edinburgh, 86; Liverpool, 91; majority for Liverpool, 5. The Association will, therefore, go to Liverpool in 1870.

On the proposal of Sir Stafford Northcote, seconded by Sir John Lubbock, Professor Huxley was elected for the presidency.

The vice-presidents, besides the *ex officio* members appointed, were—Lord Stanley, M.P., Mr. W. E. Gladstone, M.P., Mr. Graves, M.P., Mr. Joseph Mayer, Sir Philip Egerton, Mr. Joule, F.R.S., Mr. Whitworth, F.R.S.

The secretaries, treasurer, and auditors were reappointed, and their services in the past year were spoken of in high terms of approbation.

SECTION A.—MATHEMATICAL AND PHYSICAL SCIENCE.

PRESIDENT—Professor J. J. Sylvester, M.A., LL.D., F.R.S. Vice-Presidents—Professor J. C. Adams, M.A., D.C.L., F.R.S.; J. P. Gassiot, F.R.S.; William R. Grove, M.A., F.R.S.; Professor Bartholomew Price, M.A., F.R.S.; Rev. T. R. Robinson, D.D., F.R.S. Secretaries—Professor G. C. Foster, B.A., F.R.S.; R. B. Hayward, M.A.; W. K. Clifford, B.A.

At the close of the President's address, Mr. W. R. Birt, F.R.A.S., read the following—

REPORT OF THE LUNAR COMMITTEE.

IN introducing this report, Mr. Birt referred to the progress of selenographical research since the Committee was appointed at Bath in 1864. It appears that a surface of 100 square degrees, *i.e.*, 10 degrees of south latitude, and 10 degrees of west longitude, has been carefully and critically surveyed during the period; the outlines of 433 objects laid down on a scale of 200in. to the moon's diameter; and a catalogue prepared, which contains numerous notices of important and interesting phenomena bearing on questions which have lately been mooted relative to the physical aspect of the moon's surface. "The great question of continued lunar change," says the report, "either transient or permanent, as contrasted with apparent change dependent upon illuminating and visual angle is one most likely for posterity to settle. If, in geological science, a region undergoing a series of changes—during the progress of which, through a long period of geological time, lakes have been drained, volcanoes have burst forth, extensive plateaux of igneous ejections formed, and vast denudations of softer material effected—has retained its grander and more imposing features in their integrity, so in selenological science we may rather look for small, and in many cases to us almost inappreciable, changes in and around well recognized and imposing lunar forms than expect to witness the obliteration of some very striking object as an evidence of change." The report treated somewhat largely on the general question of change on the moon's surface, and several instances were adduced as proofs that the surface of our satellite had undergone successive changes during its past history. Chacornac's three great eras of lunar formation—the ancient, during which the larger craters were produced; the intermediate, or that of the overspreading of the lower levels with the material forming the grey plains or so-called seas; and the comparatively modern—restricting the term to pre-historic times—were slightly glanced at, and the existence of a series of changes analogous, but prior, to those described by Chacornac, was pointed out, and the region in which they occur considered as one of the most ancient on the moon. At a much later period of the moon's history, in a locality bordering upon this ancient tract, a series of severe successive changes was mentioned—the first being an elevation of a somewhat considerable tract of high land; the second, a fault traversing this high land; third, the formation of a crater of rather considerable magnitude; fourth, the formation of a valley on the east of this crater; fifth, the production of a line of cliffs on the north of the high land, most probably occasioned by the subsidence of a large tract still further northward; sixth, the opening of a much larger crater on the east of the crater already formed on the high land, which, having a furrowed flank on the east, the furrows were abruptly terminated, and the valley on the east interrupted by the production of this larger

crater; seventh, the upheaving of a mountain wall on the edge of a neighbouring crater on the west, this mountain wall being the highest rock in the locality. "The determination of these successive changes," says the report, "rests on the strong indications afforded by a careful study of photograms, of the priority and posteriority of well marked features, which can only be realised by contemplating the lunar picture in the seclusion of the study. While the telescopic view is far superior to the photographic, the continual changes of illuminating and visual angle prevent that appreciation of the relations of different features to certain epochs of production which can be so well studied in the photogram, the detail thus seized upon by the aid of photography is vividly realised by the eye at the telescope when the surface of the moon is suitably illuminated." The report alluded in the next place to certain differences between the photograms employed, particularly one with respect to a certain crater figured by Lohrmann, which is found on De la Rue, but not a vestige can be discovered on Rutherford. The comparison of photograms appears to open up a line of investigation of great promise. Some attention has also been given to apparent changes of brightness and tint, a subject to which Webb called attention a few years since. Three or four somewhat conspicuous spots were adduced as exhibiting these alternations, which appear to be independent of any agencies with which we are acquainted.

SECTION B.—CHEMICAL SCIENCE.

PRESIDENT—Dr. H. Debus, F.R.S., F.C.S. Vice-Presidents—Dr. Gladstone, F.R.S.; Dr. W. A. Miller, F.R.S.; Dr. Voelcker, F.C.S.; Dr. Williamson, F.R.S., Pres. C.S. Secretaries—Professor A. Crum Brown, F.R.S.E., F.C.S.; Dr. W. J. Russell, F.C.S.; Dr. Atkinson, F.C.S.

PRESIDENT'S ADDRESS.

I BELIEVE it has been the custom with many of my predecessors in this office to place before the members of the British Association a report of the progress of chemistry during the year preceding their election. In attempting to follow their example, I soon found that it would be impossible for me, without making too great a demand upon your time, to give even a bare outline of the more important chemical work done during the year. A science, the report of whose yearly advances fills about 1,000 large octavo pages, cannot by any powers of mine have its progress chronicled in an address of half an hour's duration. The best course open to me under such circumstances is to direct your attention to the ideas which at present guide chemists in their researches; to place in a clear light the objects they are striving to attain; and to indicate the direction of the scientific thought of our time. To do this is by no means an easy task; for the more manifold and diversified the objects of a science become, the more numerous and extensive its relations with other branches of knowledge, the more difficult it becomes to draw a picture of its actual condition.

It is always an excellent recommendation of a theory or hypothesis when among the cultivators of the science to which it pertains very little difference of opinion exists as regards its admissibility and scientific value. This is in a high degree the case with regard to the atomic theory. The vast majority of chemists, I believe, accept this theory as the most suitable exponent of the fundamental truths of their science; and certainly if the quality of the tree may be judged by its fruit there is no other view which furnishes a clearer image to our minds of the chemical constitution of bodies, and at the same time conducts to the discovery of so many important facts and relations. On Dalton's profound hypothesis all bodies are supposed to be composed of atoms of infinitely small dimensions. But these atoms are supposed not to be single: two or more of them are held together by certain forces and thus constitute what is called a molecule. One atom of carbon, one atom of calcium, and three atoms of oxygen, joined together by the force called chemical affinity, constitute a molecule of carbonate of lime. Vast numbers of such molecules bound to each other by the force of cohesion form a visible piece of chalk. If a chemist wishes to examine a body, his first endeavour is to ascertain of what sort of atoms the body is formed. This is a mere matter of experiment. He next determines how many of such atoms are contained in each molecule of the body; and finally he ascertains how these atoms are arranged, or, more correctly, combined within the molecule; for it is quite clear that a substance like saltpetre, which contains one atom of nitrogen, one of potassium, and three of oxygen, may have these atoms arranged in very different manners and still have the same composition. We might assume the potassium and nitrogen in more intimate union, nearer to each other than they are to oxygen, or we might consider nitrogen and oxygen more closely packed together, and, so to speak, attached as a whole to the potassium; in both cases, saltpetre would have in each molecule the same number of atoms, and the weight of the molecule would be the same.

The three determinations just mentioned are of fundamental importance to the chemist; not that such inquiries are the only ones which interest him, for we shall in the sequel notice others of almost equal importance. Nor must it be supposed that questions of this nature are of quite a modern date; for Leucippus, 500 B.C., appears to have sought to explain the nature of things by the assumption that they are formed by the union of small particles, which latter received the name of atoms from Epicurus. It is true the notion of atoms as conceived by the Grecian philosophers is not quite the same as ours, but their speculations contain our notions pretty much in the same way as the acorn contains the oak tree. The determination of the quality of the atoms in a molecule, or the analysis of the latter, has not undergone many changes during the last few years, and the same may be said about the finding of the relative weight of a molecule, or the determination of the number of atoms which are contained in it. With regard to the latter point, however, it may be mentioned that Avogadro's hypothesis, according to which equal volumes of gaseous substances, measured at the same temperature and pressure, contain the same number of molecules, guides us chiefly in assigning to each molecule its relative weight and its number of atoms; this hypothesis has won more and more the confidence of chemists, and it is now admitted to hold good in nearly all well-examined cases. Our views relative to the manner in which atoms are arranged in molecules, and our methods of ascertaining this arrangement, have, however, undergone great alterations and received great additions during the last ten or fifteen years. To a consideration of these changes, I will now, for a short time, invite your attention. Since our modern views, however, originated in a great measure in the study of organic bodies, and since the majority of chemists now devote their time and labour thereto, I shall confine my remarks principally to the organic branch of the subject.

Eighteen years ago Professor Williamson read before the members of this Association a remarkable paper which contained the germ of our modern chemical views, and was the cause of many important discoveries. He proposed to regard three large classes of bodies—acids, bases, and salts—from the same point of view, and to compare their chemical properties with those of one single elected substance. For this term of comparison he chose water. Now water is composed of three atoms, two of hydrogen and one of oxygen. Williamson showed that all oxygen acids, all oxygen bases, and the salts resulting from a combination of the two, can, like water, be considered to be composed of three parts or radicals, two of the radicals playing the part of the hydrogen atoms in water, and the third that of the atom of oxygen. Potassic hydrate is water which has one of its atoms of hydrogen replaced by an atom of potassium, hydric nitrate is water which has one atom of hydrogen replaced by nitric oxide, and potassic nitrate is water with one of its hydrogen atoms replaced by nitrate oxide and the other by potassium. This speculation, as every chemist knows, is well supported by experiments; it embraces three large classes of bodies which till then had been considered as distinct. Mr. Gerhardt, in 1853, extended Williamson's views by distinguishing two other types of molecular structure represented respectively by hydrogen and ammonia; and succeeded, by help of the radical theory, in arranging the majority of the then known substances under one or the other of the three types already mentioned. Like every theory which is in harmony with experience, the above considerations led to results of unexpected importance. For it soon became apparent that the radicals which thus replace hydrogen in water are not at all of the same chemical value. The learned gentleman entered into an elaborate and technical explanation in proof of this statement, and then went on to say:—Thus every year produces results which improve our conceptions of the atomic and molecular constitution of bodies. And as our knowledge improves, new questions suggest themselves, and our power over the elements increases. It has already become possible to prepare in the laboratory bodies of a very complex character, and which a few years ago were only found in the bodies of animals or plants. Alizarin, the beautiful compound of the madder root, has been obtained by artificial means in the course of the year by Messrs. Liebermann and Græbe. Results of such a nature render it highly probable that, at no distant period, it will be in our power to prepare artificially nearly all, if not all, the substances found in plants and animals. Here I must not be misunderstood. Organic structures, such as muscular fibre or the leaves of a tree, the science of chemistry is incapable of producing, but molecules like those found in a leaf or in the stem of a tree, will no doubt one day be manufactured from their elements.

I must not conclude this address without reference to two or three papers of great importance. Professor Bunsen, of Heidelberg, has published a paper on the washing of precipitates. Every one acquainted with practical chemistry knows how much time is often lost in waiting for a liquid to pass through a filter. Bunsen found the rate of filtration nearly proportional to the difference between the pressures on the upper and lower surfaces of the liquid. If, accordingly, the funnel be fixed air-tight by means of a perforated cork to the neck of a bottle, and the air exhausted in the bottle, the liquid will run faster through the filter in proportion to the diminution of the pressure in the bottle. Comparative experiments, some made according to the old, and others made according to the new method, showed that the filtation, washing, and drying of a precipitate, which took seven hours by the old plan, could be performed by filtration into an exhausted bottle in thirteen minutes. But a saving of time is not the only advantage of the improved method of collecting and washing precipitates. A more perfect washing, with less water than is required by the common way of proceeding, is by no means the least recommendation of Bunsen's ingenious method. A very important paper has been published by Professor Liebig on the improvement of the nourishing qualities of bread. Certain quantities of phosphates and other salts form necessary ingredients of wholesome food. Now, it is well known that most of these salts, which naturally exist in wheat, remain with the husk. Liebig proposes to add salts, of a nature similar to those remaining in the husk, to the flour, and at the same time to substitute for the carbonic acid developed by fermentation gas liberated from sodic carbonate. The bread prepared according to Liebig's recommendation is said to be of excellent quality, and to exceed in value bread made by the ordinary method. Mr. Graham, of Her Majesty's Mint, has continued his researches in the absorption of hydrogen by palladium. Palladium appears to be able to absorb more than 900 times its volume of hydrogen, and to form a combination which consists of nearly equal equivalents of the two elements. Hydrogenium, as Mr. Graham calls the combined hydrogen, acts in this case like a metal, and thus the opinion held by some scientific men, that hydrogen constitutes the vapour of a metal, receives confirmation. The specific gravity of hydrogenium, as contained in the alloy, was found to be 1·95. These experiments are remarkable in more than one respect. The palladium which absorbs and combines with the hydrogen does not change its state of aggregation, but remains solid and expands as if it had been heated. The nodules of the palladium have consequently changed their relative positions and combined with hydrogen, whilst the continuity of the metal remained intact. The last paper to which I have to draw your attention is to the beautiful paper by Professor Tyndall, on a new method of decomposing gaseous substances by means of light. Tyndall's experiments bring us face to face with the motions of atoms of molecules, and the relation of these motions to chemical decomposition. They will no doubt, at some future time, furnish valuable materials to chemical dynamics.

MANUFACTURE OF CHLORINE.

BY MR. WALTER WELDON.

THIS was an elaborate paper on the manufacture of chlorine by means of perpetually-regenerated manganite of calcium. What has hitherto been the ordinary process of manufacturing chlorine consists in digesting ores containing peroxide of

manganese with hydrochloric acid. The chloride of manganese, which is a residual product of this process, has hitherto been ordinarily thrown away. Mr. Weldon decomposes this chloride of manganese by lime, and another equivalent of lime, and then blows air through the resulting mixture of hydrated protoxide of manganese, lime, and solution of chloride of calcium. The protoxide of manganese absorbs oxygen from the injected air, thereby becoming converted into peroxide, which combines with the equivalent of lime used in excess of the quantity required to decompose the chloride of manganese, forming therewith the compound which the author calls manganite of calcium, and believes to be a new compound. The compound thus produced is employed instead of manganese ores for the liberation of chlorine from hydrochloric acid, and is then reproduced from the resulting solution of chloride of manganese, and so on continually, the same manganese being thus employed over and over again perpetually. Last year there were made in this country and on the continent about 120,000 tons of bleaching-powder, which is the chief commodity in the manufacture of which chlorine is employed, and this bleaching-powder costs on an average about £5 per ton for native oxide of manganese. Mr. Weldon's process produces bleaching-powder at a cost of only 15s. per ton for manganite of calcium, and enables much more chlorine to be obtained from a given quantity of hydrochloric acid than has hitherto been usually obtained therefrom. It is being very extensively adopted both in this country and on the continent. The author exhibited samples of manganese which had already generated chlorine about fifty successive times.

[We have the above paper in type *in extenso*, but want of space obliges us to omit it from the present number.]

SECTION C.—GEOLOGY.

PRESIDENT—Professor R. Harkness, F.R.S., F.G.S. Vice-Presidents—R. A. C. Godwin-Austen, F.R.S., F.G.S.; Sir P. Egerton, Bart., F.R.S., F.G.S.; Professor Phillips, F.R.S., F.G.S.; Professor Huxley, F.R.S., F.G.S.; Edward Vivian, F.G.S. Secretaries—W. Pengelly, F.R.S., F.G.S.; W. Boyd Dawkings, F.R.S., F.G.S.; Rev. H. H. Winwood, M.A., F.G.S.

PRESIDENT'S ADDRESS.

IT has of late become the custom to open the several sections of the British Association with an introductory address. This custom had, I believe, its origin in this section when the Association met at Aberdeen; and upon that occasion Sir Charles Lyell made the important discovery of M. Boucher de Perthes, of the occurrence of flint weapons with the bones of large extinct mammals in the gravels of the Valley of the Somme, the subject of his opening address. In some instances no matter of importance in connection with geology has furnished materials for the opening address; but more frequently subjects of local interest have supplied the matter for this purpose; and it is in connection with the latter that I shall occupy for a short time your attention. In no portion of Great Britain have we a better development of the series of rocks which forms the link between the well established Devonian formation and the succeeding well recognised carboniferous group than in this county. The rocks which form the link I refer to are known to geologists as the Pilton beds, deriving their name from the locality in Devonshire where they are best developed. These rocks have been made the subjects of investigation by Sir Roderick I. Murchison, Professor Sedgwick, Sir H. J. de la Beche, Mr. Weaver, Mr. Godwin-Austen, Professor Phillips, and others; and of late they have been carefully examined by Mr. Jukes, Mr. Salter, Mr. Townshend Hall, and Mr. Etheridge. My reason for referring to these rocks is to point out their relation to certain strata which are very well exhibited in the south-west of Ireland, and which occur in a horizon corresponding to the Pilton Shales. The Irish representatives of the Pilton Shales are marked by a mineral aspect very nearly allied to their equivalents in this country; and they contain organic remains of a type very closely approximating such as are found in the Pilton rocks. Before alluding to the Pilton beds, I will refer to their Irish representatives, and to the rocks upon which these repose. In doing so, I shall avail myself of the labours of the late Mr. Jukes and the other officers of the Irish branch of the Geological Survey, who were for several years engaged upon these rocks. Before doing so I must, however, pay a passing tribute to the memory of one who has so recently been removed from the scene of his labours. For more than eighteen years the late Mr. Jukes filled the office of Director of the Geological Survey of Ireland; and the numerous maps and memoirs which have emanated from this survey while under his control speak alike of the labour and accuracy with which this work has been done. Every geologist personally acquainted with the late Mr. Jukes must know how ready he was on every occasion to impart all the knowledge he possessed to those who sought it; and that earnest love of his subject and kindness of heart which so distinguished him caused him to be beloved by all who had the pleasure of his acquaintance. On many occasions this section of the British Association has had valued communications from him; and many who are now present will well remember the apt and vigorous manner of Mr. Jukes when he had anything to address to this section.

The portion of Ireland nearest Devonshire where we have rocks which can be compared with those of this county is the neighbourhood of the town of Wexford. Here are strata reposing upon Cambrian rocks, which have been assigned to the old red sandstones by the officers of the Irish Survey, attaining a thickness of about 200ft. At the western extremity of the county of Wexford, at Hook Point, the old red sandstones are from 600ft. to 700ft. thick. In the Comeragh Mountains to the north-west they have a thickness of not less than 1,700ft; and south-west from the Comeraghs, near Dungarvon, they are upwards of 3,000ft. in thickness. In the west of the county Cork we have from 5,000ft. to 6,000ft. of old red sandstones exposed; and here the upper portion is denuded and the base is not seen. In the Glengariff and Killarney country from 8,000ft. to 10,000ft. of these strata are exhibited, and here also their base is not visible. On the south side of the Dingle promontory the old red sandstones occur under different circumstances. They are here from 3,000ft. to 4,000ft. thick, and are seen resting unconformably on rocks which are of a reddish purple colour, and being at least 10,000ft. thick. These reddish purple beds repose comformably on the representatives of the Ludlow series. The strata of the South of Ireland which represent the old red sandstones, and which in the neighbourhood of Glengariff and Killarney attain a greater thickness than 10,000ft., are extremely barren in organic remains. Several thousand feet of strata, consisting of purple, red, and green beds, which, from being well developed in the district of Glengariff, have received from the Irish Geological Survey the name of "Glengariff Grits," have never yet afforded a fossil. It is only in the upper portions of the series, which is comparatively thin, and which consists of yellow sandstones, that organic remains occur; these consist of remains of plants, which at Kiltorkin, in the county Kilkenny, are in a beautiful state of preservation. Fish remains are also found referable to the genera *Coccosléus* and *Gyrolepis*; likewise a very characteristic shell, *Anodon Jukesii*, and crustacean remains in the form of a species of *Eurypterus*. In Ireland the strata which succeed conformably the yellow sandstones have been called by Sir R. Griffiths the lower limestone and shales. In the south of Ireland these strata have a great thickness, and when they possess a slaty cleavage the term "carboniferous slate" has been applied to them. These strata in the eastern portions of the county Wexford, where the old red sandstones are thin, have no distinct existence. In the western part of the same county, at Hook Point, where the old red sandstone deposits are thicker than in the eastern portion of Wexford, the lower limestone shales make their appearance as a distinct group, separating the yellow sandstones below from the carboniferous limestones above; and here their thickness is between 10ft. and 20ft.

We have already seen how the old red sandstones have increased in thickness in the neighbourhood of Dangarvon. The carboniferous slates also attain a much greater development here than at Hook Point, for the officers of the Geological Survey give their thickness at 700ft.; and near Youghal, still further westwards, they have a thickness of about 900ft. On the western side of Cork Harbour, we have examples of a still greater development of the carboniferous slates, for here they are at least 1,500ft. thick. At the Owl Head of Kinsale, 6,500ft. represent their thickness; and still further westward, they attain to even a greater development. In the county of Cork, gritty bands make their appearance in the carboniferous slates. In the eastern portion of the area, where the grits first occur, they are thin and very irregular. They become very thick in the western portion of the county; and in Coomholn Glen they have their greatest development, being at least 3,000ft. in thickness. These gritty beds have been termed "Coomholn grits." They contain some peculiar fossils, and they have others in common with the carboniferous slates. They are interstratified with slate bands; and, although most extensively developed near the base of the carboniferous slates, they are merely local members of this series, emanating from conditions somewhat different from those whence the great mass of the carboniferous slates originated.

Having described generally the arrangement of the rocks of the South of Ireland which represent the Pilton beds, and also the deposits which support them, we have now to refer to North Devon. On the north side of Boggy Point, and eastward thereof, there are hard purple sandstones, possessing many of the features of the sandstones of the South of Ireland, which immediately underlie the "yellow sandstones," and upon those in North Devon are light-coloured beds, which represent the Irish yellow sandstones. In the neighbourhood of Marwood, reposing on the equivalent of the yellow sandstones, are greenish-grey grits, affording a group of fossils intimately allied to those contained in the Coomholn grits; and among these are plant remains identical with such as occur near the base of the carboniferous slates. These have been obtained by the Rev. Mr. Mules. The mineral nature and the fossil remains place the Marwood sandstones and the Coomholn grits on the same horizon. The fossil plants which occur near the base of the carboniferous slate, and in the Marwood sandstones, are specifically identical with such as are found at the base of the carboniferous formation in the north of England. Here *Felicites liniaris* and *Sagenaria Velthemiana* occur, and these are the forms which the base of the carboniferous slates afford. The Pilton rocks succeed the Marwood sandstones, and these Pilton rocks, in their mineral nature, are intimately allied to the carboniferous slates. The strata which make up the Pilton group consist of shales and slates, generally of a dark colour, with associated sandstones and gritty beds, and occasional thin bands of limestones full of corals. The fossils of the Pilton rocks are very closely connected with those of the carboniferous slates. Forms, however, occur in the Pilton beds which have not yet been recognized in their Irish representatives. There are species of *Phocops*, *Strophalosia productoides*, and a few other species. But such fossils as are most abundant in the Pilton rocks are those which are most common in the carboniferous slates. There is an idea prevalent among many English geologists that the Coomholn grits are a series of rocks distinct from and lying beneath the carboniferous strata; and this idea has, I believe, given rise to erroneous impressions concerning this series. I have pointed out that this is not the conclusion of the officers of the Irish Geological Survey, and my own observations have led me to results similar to theirs. I hope this meeting will afford more information concerning the Marwood beds and the Pilton rocks; and that we shall have further evidence which will enable geologists to say whether these strata shall be referred to the Devonian group or to the carboniferous formation. A band of pale slates, with a few bivalves, lies between the purple sandstones of Mort Bay and the greenish-grey grits of the Marwood series. It is desirable that further information should be afforded concerning these strata and their fossil contents. It appears to me that the boundary between the Devonian or old red sandstones and the carboniferous formation is, in the British Isles, placed in different horizons. In Ireland, the carboniferous slates and the interbedded Coomholn grits are referred to the latter, while, in this country, the equivalents of these are looked upon as appertaining to the Devonian formation.

Besides the Marwood sandstones and the Pilton rocks, there are other matters of great interest in connection with the geology of Devonshire. The Triassic strata of this county in the neighbourhood of Budleigh Salterton has within it some peculiar pebble beds, which have been described by Messrs. Salter and Vicary. These pebble beds abound in fragments containing fossils similar to those which the Silurians of Normandy offered. Recently these Triassic strata have yielded to Mr. Whitaker important palæontological evidence in the form of reptilian remains, which Professor Huxley has referred to the genus *Hyperodapedon*. This evidence goes a long way towards supporting the conclusion that the Lossie-mouth sandstones near Elgin are of a much newer age than their stratagraphical arrangements would seem to indi-

cate; and that they belong to the triass rather than to the old red sandstones, to which they have previously been referred by many geologists. In Devonshire also we have a better development of the Miocene strata than is to be found elsewhere in the British Isles, and the locality where these strata occur is within a short distance of Exeter. I refer to Bovey Tracey and its lignite beds. The plant remains which have been obtained therefrom have been described by the eminent Swiss botanist, Dr. Oswald Heer; and, thanks to the generosity of that noble-hearted lady, Miss Burdett Coutts, who is alike desirous to promote science and to alleviate human suffering, the fossils obtained from these Bovey Tracey lignites are now well known to geologists. The plant remains which these strata contain are the relics of a vegetation which, during the lower Miocene epoch, spread over a large portion of the continent of Europe, and extended into the arctic regions of America; a vegetation which clothed not only Europe with lofty forest trees and a rich undergrowth of smaller plants, but which also covered Greenland and Spitzbergen, lands which are now the abode of ice and snow, with an equally rich vegetation. This extensive diffusion of similar forms of plants during the old Miocene period speaks to us of a widely extended uniform climate, contrasting strongly with the climates which now prevail in the temperate and arctic regions of the northern hemisphere. There is another matter connected with the geology of Devonshire which has special interest. This is the caves of this county, and their contents. These have been made the subjects of many valuable communications to this section by Mr. Pengelly and the gentlemen who are associated with him in the committee for the exploration of Kent's Hole. But as we now are in a locality so near the source whence so much of interest has come, I believe that this section will again have before it important matter referring to Kent's Hole, and other Devonshire caverns. Geology and archæology are now shading into each other, and although the early history of man remained for a long time like distant land, dim and ill-defined, of late, owing to the labour of Sir Charles Lyell, Sir John Lubbock, and others, we are now acquiring a clearer conception of our early ancestors, of their mode of life, and the conditions under which they existed.

SECTION D.—BIOLOGY.

President.—George Busk, F.R.S., F.L.S., F.G.S. Vice-Presidents—Professor Balfour, F.R.S.; C. Spence Bate, F.R.S., F.L.S.; Dr. Hooker, F.R.S.; Sir John Lubbock, Bart., F.R.S.; Dr. W. Ransome; E. B. Tylor; A. R. Wallace, F.R.G.S.; Professor E. Perceval Wright, M.D. Secretaries—Dr. Spencer Cobbold, F.R.S.; Professor Michael Foster, M.D.; E. Ray Lankester; H. T. Stainton, F.R.S., F.L.S.; Rev. H. B. Tristram, M.A., LL.D., F.R.S.; Professor Lawson.

On taking the chair the President apologised for not delivering an address. He had been obliged to forego giving an address on the present occasion because he occupied the chair only on account of the absence of a much more worthy occupant, his eminent friend Dr. Rolleston, who had been prevented attending; and it had now fallen to his lot, and that at such brief notice, at a time when he was much engaged, so that he had been quite unable to prepare any address which would be worthy of their attention. He had, however, a few observations to make as to the arrangements of the section. They had followed the arrangements of the last two or three years, in dividing the section into two different departments, which were, first, one including all subjects of natural history, botany, zoology, and ethnology; and the second included the subjects of human and comparative anatomy and physiology. With respect to the ethnology it was determined by the committee that the subject should be added to the first of the classes into which the section had been divided, because the subject had been separated from its somewhat unnatural union with the geological section last year. It had long been thought, and sometimes warmly debated, whether such union of ethnology with geology should be allowed to remain this year. However, the word ethnology had not been coupled with the geological section, and as it did not appear desirable that so highly important a study as the study of the human race and their history should be left out of the proceedings they had taken it up. It was perfectly clear that it was as important a subject as could be brought before them, and it was one which, year after year, acquired greater importance, and for that reason it had been added to their list of subjects. On the present occasion it happened that the number of subjects upon ethnology was not sufficient to justify their occupying a separate apartment, and as the inconvenience attending that course was considerable, it had been determined that two days out of the week should be given to ethnological subjects.

The section then divided and sat in two departments—one for zoology and botany, under Mr. Spence Bate, and the other, anatomy and physiology, under the president of the section, Mr. Busk.

In the Zoological and Botanical Room, presided over by Mr. C. Spence Bate, the first report read was by Mr. H. E. Dresser, of the "Close Time" Committee. Mr. Dresser advocated a close time being secured for various birds in the same manner as is secured in foreign countries. The discussion was principally remarkable for the remarks of Professor Huxley against having a close time at all, and against the Preservation of Animals, &c., Act, particularly in its application to the deep sea fisheries. The learned Professor contended that that Act was useless, mischievous, and meddling, and stated that the gulls, which had been protected by recent legislation, were of no further use, and could be put to no higher service, than when they furnished their plumage to surmount the bonnets of the interesting sex. The learned Professor generally ridiculed the idea of having a legislative "close time" for such birds. Opposite views were advocated by the Rev. H. B. Tristram, Mr. Wallis, and Professor Newton, and Miss Becker. Some very interesting examples were given by Mr. Smith of the effect of the preservation of birds in the Scilly Isles. He had preserved birds there for many years, and found that while some would increase others would decrease, being pushed out by stronger and more rapacious kinds of birds. The Rev. H. B. Tristram read a paper on the "Effect of Legislation on the Extinction of Animals," strongly advocating legislative means being used to prevent the extinction of wild animals, and particularly birds. In the discussion which ensued, the opinions generally expressed were in favour of this view.

SECTION E.—GEOGRAPHY.

President—Sir Bartle Frere, F.R.G.S., K.C.B., G.C.S.I., LL.D. Vice-Presidents—Sir G. Grey, K.C.B., F.R.G.S.; A. G. Findlay, F.R.G.S.; General Sir A. Scott Waugh, R.E., F.R.S; Captain Richards, R.N., F.R.S.; Admiral Sir E. Belcher, K.C.B., F.R.G.S. Secretaries—H. W. Bates, Assistant-Secretary, R.G.S.; Clements R. Markham, F.R.G.S.; J. H. Thomas, F.R.G.S.

President's Address.

In opening the proceedings of this section, I have no intention to attempt any systematic summary of the progress, present state, or prospects of geographical science generally. My object will be simply to state the proposed course of our proceedings in this section of the Association, and to inform you very briefly on what particular points we may expect to hear from the associates, or from visitors who honour us with their presence, information which may be either new in itself or may form the basis of useful discussion.

Polar discovery seems by universal consent to have a sort of precedence in all classification of recent geographical inquiry, and in this branch we cannot expect much that is new to be laid before our present meeting. We are now in the midst of the very brief season during which an Arctic summer allows the navigator for a few weeks only any chance of making fresh discoveries, and cannot for some weeks longer hear what measure of success may have attended attempts like that of Mr. Lamont to extend our knowledge of the regions adjacent to the North Pole, and especially to solve the present great Arctic problem as to the existence of a great open Polar basin, and we must not expect too much. We may, however, hope to hear something of interest to geographers with regard to the prospects of Antarctic discovery in connection with the preparations for observing the coming transits of Venus. Geographers and astronomers will sympathize less than other taxpayers with the Chancellor of the Exchequer when he finds even the heavenly bodies moving for a parliamentary grant. We may wonder with Mr. Lowe that even Venus cannot arrange a transit without an application to the British Treasury, but we may hope that Parliament, when the application does come before them, will not be less liberal than they were in the days of Cook, exactly a century ago, and that they will regard the investigation as one of really national importance.

There are amongst us, I am glad to hear, more than one geographer who will represent that vast Russian empire whose territories extend in so many directions into regions comparatively unknown, and whose government has long been so honourably distinguished by the aid it has afforded to geographical science. It may, I believe, be truly said that along the line of thousands of leagues which form the southern boundary of the Russian empire in Asia, there are scarcely a hundred miles regarding which our knowledge is as complete as could be desired. We shall have among us Mr. Douglas Forsyth, honourably distinguished among those who, like Captain Montgomery and his fellow labourers, have led the way in geographical discovery to the north of India, and contributed to lift the veil which has for so many generations separated the inhabitants of Tartary and Thibet from those of India. He will give you, I hope, much interesting information regarding the trade routes towards Thibet and Eastern Chinese Tartary, and will satisfy you that he is actuated by no motive dangerous to us or our neighbours, but by a sincere desire to extend the peaceful domain of commerce, and, as a handmaid thereto, to aid the cause of geographical discovery. He will give you the latest intelligence of that enterprising traveller Mr. Shaw, who is at Yarkand, well treated, and apparently a special favourite with both rulers and people.

Mr. Trelawney Saunders will read a paper in which he has combined some of the latest information acquired by Captain Montgomery and his intelligent and enterprising assistants, the Pundits, and applied it to illustrate the general geography of the Himalayan range. Much as has been written about that vast chain, it can hardly be said that even professed geographers have any adequate conception of the bulk and importance of that great mountain mass. Its length may be said to be still almost a matter of conjecture, for its eastern and western terminations have both still to be defined. Its breadth, as Captain Montgomery, who may be said first to have spanned it, tells us, is more than 400 miles at its narrowest, or about eight times the average width of the Alps, with a summit ridge, the passes over which average about 15,000ft. in height.

The Association will recollect that the latest intelligence regarding the course of the Sanpoo, the great river which runs so far from west to east in a course nearly parallel to the general direction of the main Himalayan range, has revived a former discussion as to whether that river rises in the upper stream of the Burrumpootra or of the Irrawaddy. The supposition that it was identical with the Irrawaddy has long been considered as set at rest, and some of our best authorities, such as Drs. Hooker, Thomson, and Campbell, would, I believe, scout the notion that there was any present doubt on the subject. Still it is certain that some Chinese and Thibetan informants have assured later travellers that the Sanpoo is the upper stream of the Irrawaddy, and we are almost destitute of any accurate data regarding the course of the Burrumpootra much higher up than the Sudiya. It is clear, then, that there is need of further inquiry before the question can be said to be finally set at rest.

The glory of being the first, in modern days, actually to traverse the almost unknown region between the Indo-Chinese races and China Proper has been reserved for our neighbours the French. The summary of the results of this great French expedition was given by our President in his last anniversary address, wherein Sir Roderick Murchison described the general course of a journey almost unparalleled in modern days—a journey of 6,200 miles from the tidal waters of the Cambodgia River to Shanghai, 2,480 miles of the distance having been traversed on foot; the whole distance, with very few exceptions, being almost entirely new to modern European travellers. I am not sure whether we are likely to hear from any of our visitors any details of this expedition beyond what has been already published in the French geographical periodicals, but we cannot doubt that whenever the scientific results of such a journey are published, they will prove of surpassing interest. A country so rich and varied in soil, with a rainfall probably in parts exceeding that of almost any known portion of the globe and a great variety of temperature, which has been hitherto almost cut off from civilized Europe, while it approximates geographically to some of the most interesting regions of India and the Eastern Archipelago, must possess a fauna and flora of great novelty and interest.

It is a great disappointment that another year should have passed without revealing, as far as I am aware, a single new fact which would throw light on the fate of Livingstone. The additional information which we have received since last the Association met is purely negative, and adds literally nothing to what was then laid before you in the masterly sketch of Livingstone's ascertained progress contained in Admiral Richard's address. We still only know that, up to December, 1867, he was alive and well, and in good spirits, travelling westward from the neighbourhood of Lake Nyassa, and that he disappeared in the obscurity of the regions beyond. Further than this all is conjecture —whether we may hear of him in the Nile Basin from Sir Samuel Baker's expedition, or on the west coast, must for the present be pure subject of speculation.

There can be little doubt that great results may be looked for from the Egyptian expedition up the Nile under Sir Samuel Baker, which is so totally unlike in its conception and objects to anything of modern days, and for any parallel to which in its difficulties and in the important results it may produce, we must go back to the days of our earliest English, Spanish, and Portuguese discoverers. I am assured Sir Samuel's hopes point to passing next Christmas on Lake Nyanza—and if he does that he will have achieved more than, with such a great expedition, could be expected even from his skill, energy, and enterprize.

In West Africa, Mr. Winwood Reade, under the auspices of the Royal Geographical Society, and Mr. A. Swanzey, one of those liberal merchants to whom geographical discovery on that coast owes so much, is on his way to the sources of the Niger. Mr. Sterling will give you an account of his visit to the holy city of Fez, which has been long kept so sacred from the foot of any but Mahommedans that I believe few European travellers in modern days, except Lord St. Maur, have visited it. We cannot turn from Africa without a passing tribute to the great French engineer who has reversed the geological revolutions of ages before the birth of history, and restored Africa to that insular position which the vast continent occupied in the geography of times preceding the early dawn of authentic history. Mons. Lesseps' great work itself may seem to belong of right to another section of this Association, but geographers must recollect how much of our geographical discovery is due to the closing of this ancient route to the East. Had the action of the Moslem powers not interfered with the Genoese and Venetian trade with the East, the discoveries of Columbus and Vasco di Gama and Magellan, and even those of Hudson, Baffin, and Frobisher, might have been delayed for generations; and now, such are the insatiable demands of commerce, no sooner has the genius and energy of M. Lesseps removed one great barrier to this ancient trade route, than mercantile men turn their attention to others still shorter, and investigate the long-forgotten geography of those lines by which the commerce of the Persian Gulf and India used to reach Tyre and Palestine in a route via Tadmor and the valleys of the Tigris and Euphrates.

In South America Mr. Chandlers is carrying out single-handed, and I believe at his own expense, his wonderful surveys of the tributaries of the Amazon. I trust Mr. Bates will give us some account of labours with the value of which, as well as with the difficulty attending them, no man is better acquainted than our indefatigable secretary. In North America, the Great Pacific Railway, which has just been opened, must exercise a very important influence in making us better acquainted with the little known regions which, for hundreds of miles, lie on both sides of its course.

Turning from the land to the sea, we find almost every month adding to our knowledge of the depth and conditions under which animal life is sustained in the great ocean beds. The extraordinary results obtained by Dr. Carpenter and his companions in their examinations of the deep-sea soundings of our Northern Ocean will be fresh in the recollection of associates, and I trust we may at this meeting hear some of the details of their labours. The laying of the French electric telegraph line, also, cannot fail to have furnished many new facts regarding the ocean bed which the cable—at present, I believe, the longest in the world—passes over, and there are other examinations of ocean beds in the Eastern Seas, commenced with the contemplated laying of the cable to India from Suez, which cannot fail to be new and interesting, on which our indefatigable associate, Captain Sherard Osborne, if he is present, would be able to enlighten us. Information of this kind is likely, as ocean electric cables multiply, to increase in value. When first such cables were laid, it was usual to select comparatively shallow portions of the ocean bed for the cable to traverse, and the deep ocean valleys and hollows were, as far as possible, avoided. But experience shows that in the deepest water the cable is safest from injury, especially in latitudes where there is risk of icebergs which may ground and destroy the cable. Hence our electric telegraph cable companies are likely to become valuable allies to geographical exploration in all that relates to our deepest ocean cavities.

The President concluded a lengthy address by enumerating several distinguished foreign geographers and stating their claims to a warm welcome. He then said:—I have been commissioned by Sir Roderick to state how deeply he regrets that he has been prevented being present this day to offer to these distinguish foreigners the expression of that hearty appreciation and welcome which would come more fitly from the President of our Royal Geographical Society, and you will all join with me in my regret that our venerated friend and leader is not here himself to give to that welcome the personal weight which it would derive alike from his official position and from his scientific standing among the first of living European geographers.

SECTION F.—ECONOMIC SCIENCE AND STATISTICS.

PRESIDENT—The Right Hon. Sir Stafford H. Northcote, Bart., C.B., M.P. Vice-Presidents—T. D. Ackland, M.A., D.C.L., M.P.; Lord Stanley, F.R.S., M.P.; Lord Houghton, D.C.L., F.R.S.; Sir W. Tite, F.R.S., M.P.; Dr. William Farr, D.C.L., F.R.S.; Professor J. E. Therold Rogers, M.A. Secretaries—Edmund Macrory, M.A.; Frederick Purdy, F.S.S.

PRESIDENT'S ADDRESS.

THE PRESIDENT read an introductory address. After dwelling at some length on the range and method of Economic Science, the right hon. baronet made the following remarks with respect to Devonshire:—And here may I venture as a Devonshire man, while bidding you heartily welcome to the county, to bespeak your indulgent consideration of the circumstances of my compatriots? We Devonians do not hurry on in the race of life quite so rapidly as some of our fellow-countrymen. Perhaps I may venture to say without offence that, as compared with north countrymen, we live slowly. Our birth-rate is below the average of England, and so is our marriage-rate; but then it must be remembered that our death-rate is also low. If you compare us with Lancashire, for instance, you will find that, for less than 32 births per 1,000 in proportion to the population here, there are more than 38 per 1,000 there (the precise figures for 1867 are—Devon, 31·75; Lancashire, 38·19); that, for less than 16 marriages per 1,000 here, there are more than 19 per 1,000 there (Devon, 15·72; Lancashire, 19·04). But then, for less than 20 deaths per 1,000 here, there are nearly 27 per 1,000 there (Devon, 19·72; Lancashire, 26·83). So again, you will find that our children die less rapidly than theirs, and our old people attain to greater ages. The proportion which the deaths of children under five years of age bears to the births in the year is, in Devonshire 19 1-3 per cent., and in Lancashire 32½; while the proportion of deaths of people over 65 years of age is, in Devonshire 18¼ per cent., and in Lancashire 8¾ per cent. Our marriages, too, take place at a more advanced age than do theirs. Of our men only 6·05 per cent. marry under 21 years of age; of theirs 8·45 per cent. do so. For women, the proportions are, in Devonshire 16·81 per cent., and in Lancashire 21·10. In short, we are born, we marry, and we die more slowly than they do. But we are not behind them in all things. If the state of education is to be judged of by the proportion of married people who can write their names, we may hold up our heads even by the side of Lancashire. Of our bridegrooms (in 1867) 82·7 per cent. wrote their names like men; of theirs only 76·8 per cent. Our brides did still better in proportion: 78.6 of them wrote their names, while in Lancashire only 56·0 did so. In the matter of wealth no doubt we are behind them; our assessment to the Schedules A, B, D of the income-tax comes to only £10 12s. per head of our population, while theirs comes to £18 14s. On the other hand, I doubt whether we have a very much larger number of paupers in proportion to our population than they have (on the average of the three years 1866-7-8 they seem to have had 65 able-bodied paupers to every 10,000 of the population, while we had 69). As regards criminals, we fall far short of their ratio; the proportion of persons committed or bailed for trial in 1867 having been in Devonshire less than 4 to 10,000 and in Lancashire 12 to 10,000. There are many other points on which it would be interesting to compare the two counties; and the comparison would be rendered still more valuable by extending it to other counties, of which these might be taken as the types. But time forbids my entering into the details which would be requisite. I refer to the point principally for the purpose of reminding you that observations which might have been applicable in one part of England may be very much out of place in another; that each county has lessons of its own to teach, as well as to receive; and that Devonshire, though she does not aspire to the position of Lancashire, as the standard-bearer of British manufacturing and commercial enterprise, is not without her own claims to respect and admiration in regard to many of the essentials of human happiness. In the concluding portion of his address, Sir Stafford entered elaborately into considerations of the question of Free Trade, and the question closely related to it of the carrying on of great enterprises, like the telegraph and the post-office, by Government, rather than by individuals, remarking upon the increasing tendency of things in that direction in Great Britain.

SECTION G.—MECHANICAL SCIENCE.

PRESIDENT—C. W. Siemens, F.R.S. Vice-Presidents—G. P. Bidder, C.E.; C. Vignoles, C.E. F.R.S., F.R.A.S.; Professor W. M. Rankine, F.R.S.; Professor Willis, F.R.S.; C. H. Gregory, Pres. I.C.E.; Admiral Sir E. Belcher, K.C.B.; Captain Douglas Galton, R.E., C.B.; J. F. Bateman, F.R.S.; F. J. Bramwell. Secretaries—P. le Neve Foster, M.A.; W. Smith, C.E.; H. Bauerman.

PRESIDENT'S ADDRESS.

IN prefacing our proceedings with a few remarks on the leading subjects of the day of special interest to our section I can scarcely pass over the somewhat hackneyed question of technical education. The great International Exhibitions proved that although England still holds her ground as the leading manufacturing country, the nations of the continent have made great strides to dispute her pre-eminence in several branches, a result which is generally ascribed to their superior system of technical education. Those desirous of attaining a clear insight into that system, and the vast scale upon which it is being carried out under Government supervision, cannot do better than read Mr. John Scott Russell's very able volume on this subject; they will no doubt agree with the author in the necessity of energetic steps being taken in this country to promote the work of universal education, although I, for one, think that objection may fairly be made against the plan of merely imitating the example of our neighbours. The polytechnic schools of the continent, not satisfied to impart to the technical student a good knowledge of mathematics and of natural sciences, pretend also to superadd the practical information necessary to constitute them engineers or manufacturers. This practical information is conveyed to them by professors lacking themselves practical experience, and tends to engender in the students a dogmatical conceit which is likely to stand in the way of originality in the adaptation of new means to new ends in their future career. On this account I should prefer to see a sound "fundamental" education, comprising mathematics, dynamics, chemistry, geology, and physical science, with a sketch only of the technical arts, followed up by professional training, such as can only be obtained in the workshop, the office, or the field. The universal interest evinced throughout the country in the work of education, by Parliamentary enquiries, by the erection of colleges and professorships, and by the munificence of a leading member of our section in endowing a hundred scholarships, are proofs that England intends to hold her place also in this question of education among the civilised nations, and I am confident that she will accomplish this object in a manner in unison with her practical tendencies and independence of character.

Closely allied to the question of education is that of the system of letters patent. A patent is, according to modern views, a contract between the commonwealth and an individual who has discovered a method, peculiar to himself, of accomplishing a result of general utility. The State, being interested to secure the information and to induce the inventor to put his discovery into exe-

COAL-GETTING MACHINE.

BY MR. J. S. WALKER.

FIG. 1.

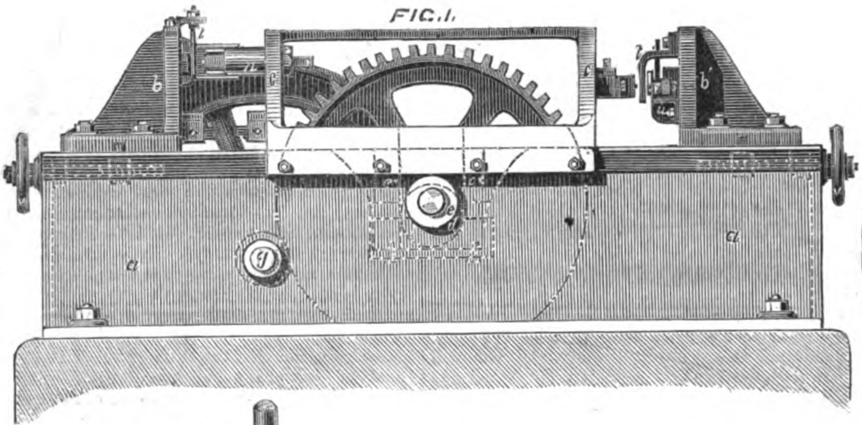

FIG. 2.

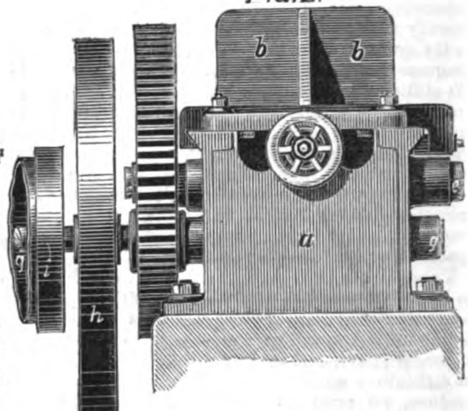

FIG. 3.

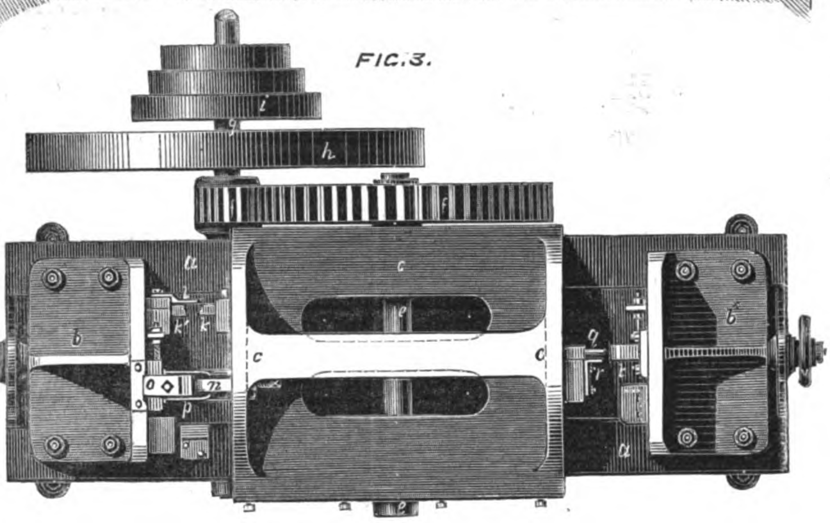

FIG. 4.

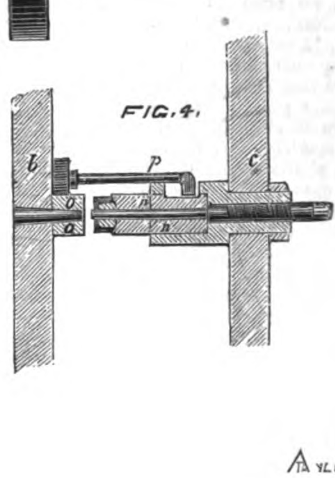


MACHINERY FOR GETTING COAL.

THE invention illustrated in the accompanying engraving relates to a method of getting coal, ironstone, or other similar mineral by the process called undermining or holeing, wherein a recess or channel is cut or grooved out near the bottom or floor. When the support is thus removed, the upper part of the coal or mineral is detached and brought down by inserting wedges above. The invention, which has been patented by Mr. J. S. Walker, of Wigan, consists principally in the employment of a peculiar form of disc cutter, mounted horizontally on a short vertical shaft and driven by bevel gearing actuated by a compressed air engine, the whole being mounted on a carriage supported on wheels running on a tramway and propelled slowly along the face of the coal or mineral by means of worms and worm wheels, also actuated by the same or an auxiliary compressed air engine. In our engraving, fig. 1 is a longitudinal section, and fig. 2 a plan view of this apparatus.

The framework *a a* of the machine is of wrought iron, carried by flanged wheels *b b* on the tramway *c c*. This framing supports the cylinder *d d* (see also face view fig. 3), crank shaft *e e*, and other parts of a compressed air engine of the ordinary construction. The crank shaft *e e* turns in bearings, and has keyed near one end the toothed pinion *f f*, the teeth of which are slightly tapered to enable it to gear with the open radial teeth *g g* formed between the inner and outer rims of the cutter wheel *h h**, the boss of which turns on a vertical stud *i i* carried by the frame *a a*. The outer rim of the cutter wheel *h h* is provided on its periphery with snugs or projections, between which the cutters *k k* are fixed by means of keys. In front of each cutter is bolted a piece of metal * * which acts as the brake iron of a carpenter's plane, and prevents the cutters from attacking the coal too deeply at once. This piece is lined with wood, which can be easily pared away as the cutters become worn. The cutters are mounted in groups of four or five, following each other, so formed and arranged that each successive cutter attacks a different part of the groove or channel cut by the wheel, and the whole group leaves no part uncut, the face of the widest cutters being wider than the rim of the wheel so as to allow of sufficient clearance, and the spur teeth *g g* are open or slotted completely through the wheel *h h** so as to allow the cuttings to fall through the openings and thus prevent the choking of the cutting wheel. The wheel *h h** is made in two parts, bolted together when in use by means of plates *l l* (see fig. 3, and also the detached sections, figs. 4 and 5). The boss of the part *h* turns on the stud *i i*, whilst the boss of the other part *h** is of a larger diameter and fits outside on the former, so that, upon unbolting and removing the plates *l l*, and lowering the stud *i i*, by unscrewing the bolt *m m*, as seen at fig. 4, the half *h** of the wheel can be turned half way round and brought over the half *h*, so that the whole of the wheel lies beneath the frame, and the width of the machine is reduced by nearly one-half. The object of this arrangement is to facilitate the transport of the machine from place to place, and to enable it to pass through parts of the mine where it would be impossible to introduce it with the cutter wheel in its entire state. *n n* are four screws, by means of which a certain amount of inclination may be given to the machine if desired, or whereby the machine may be levelled if preferred, notwithstanding any inequality in the level of the rails or tramway. *o o*, fig. 1, is a sheet-iron cover, which may be applied to the machine.

The machine may be caused to progress by driving one of the axles slowly by means of a worm and wheel, actuated either by the same compressed air engine, or by a small auxiliary air engine carried in the vacant space of the frame *a a* in front of the rear axle. Mr. Walker, however, prefers to fix a rope to the front part of the machine and draw it forwards by means of a winch or crab placed in advance. When the machine is upon a slight incline, it will advance without any external aid. By a slight modification, this machine can readily be adapted to hole or cut the coal or other mineral at the sides or near the top of the seam if required.

We are informed that this machine is daily at work with very satisfactory results. In coal without "bone" it will hole at the rate of from 30 yards per hour and upwards with 20lb. pressure, and requiring the attendance of one man only. We hope shortly to place before our readers some authenticated results of continuous working of this useful apparatus.

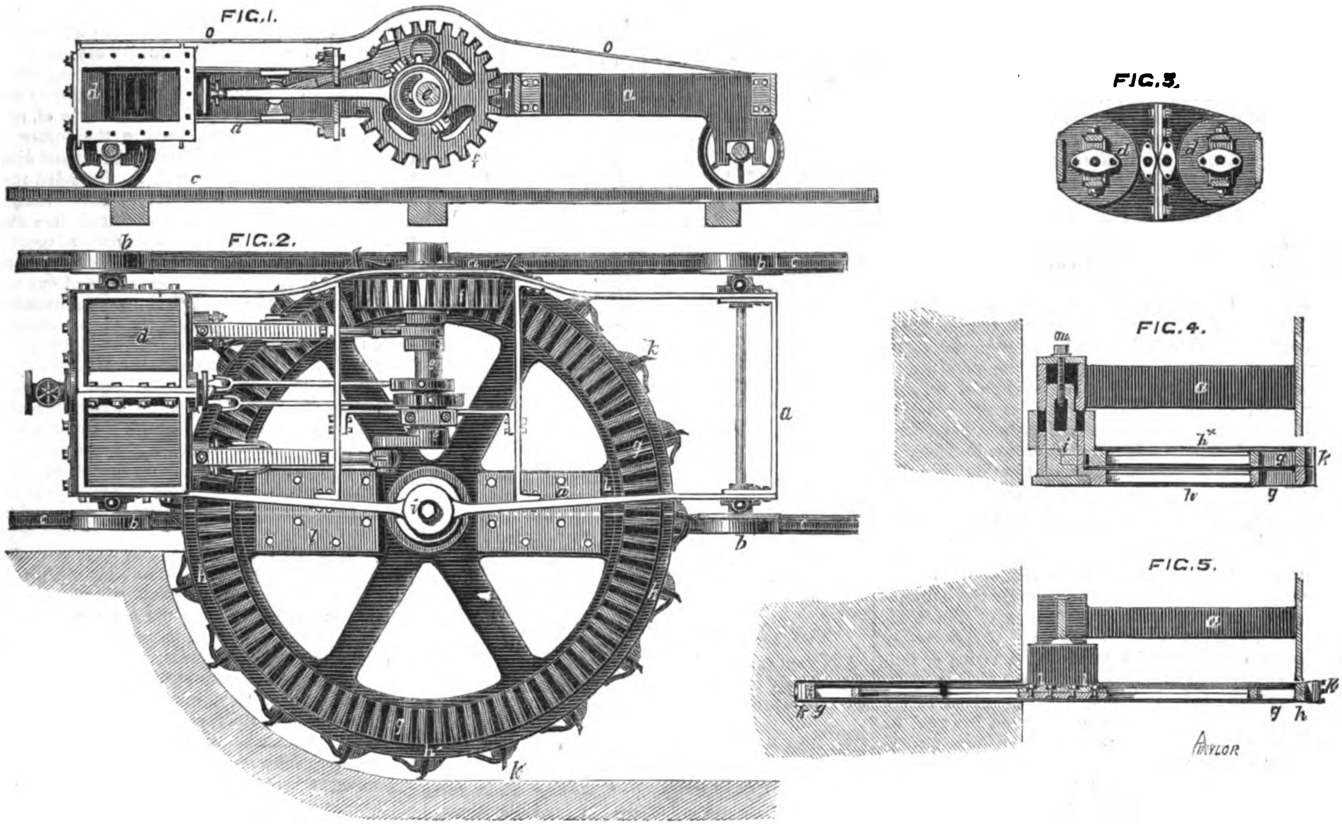
MACHINERY FOR FORGING NUTS.

MR. J. W. BRIERLEY, of Oldham, has patented some improvements in machinery for forging nuts. The invention consists of a machine which, by the simple movement to and fro of a headstock upon a slide or bed, shapes, flattens, and cuts off the nuts from a heated bar and delivers them sufficiently hot for the workman to finish them with a few strokes of the hammer on a swage attached to the anvil. The machine consists mainly of three parts, viz., a bed or slide, a fixed headstock, and a moving headstock. The latter slides to and fro on the bed, and is actuated by means of an eccentric cam or crank on the main driving shaft, which revolves with a slow motion. Attached to the sliding headstock are the tools or dies, and to the fixed headstock are attached the counterparts. The first is a die or swage, which indents the sides of the heated bar so as to form four sides of an hexagonal nut. The second is a compound tool forming a pair of squeezers or flatteners for pressing the top and bottom of the nut so as to bring it to the required thickness, and snapping the edges, and which at the same time punches out the centre and cuts off the nut.

The machine requires two attendants, a feeder and a finisher. The feeder takes a heated bar of the requisite width and presents its edges to the dies or swages, which at one movement indent the edges and form four sides of the nut. He then turns the bar on edge and places the sides between the squeezers or flatteners, which give the nut the required thickness and flatten it and snap the edges, at the same time punching out the hole in the centre and cutting off the nut from the bar. As the nut falls off, it is taken up by the finisher on a rod which fits the hole and finished (without reheating) by a few blows of the hammer on a swage of the proper form fixed on the anvil. Gauges or stops are affixed to the first and second tools, against which the feeder thrusts the end of the bar, thus ensuring the uniform size of the nuts and correct position of the central hole. These gauges are adjustable and the tools also are capable of being changed so as to make various sized nuts with one machine. For square nuts only one compound tool is required. The machine may be made double-acting by causing the moving headstock to slide between two fixed headstocks and having a similar set of tools at each end. The

MACHINERY FOR FORGING NUTS.

BY MR. J. W. BRIERLEY.

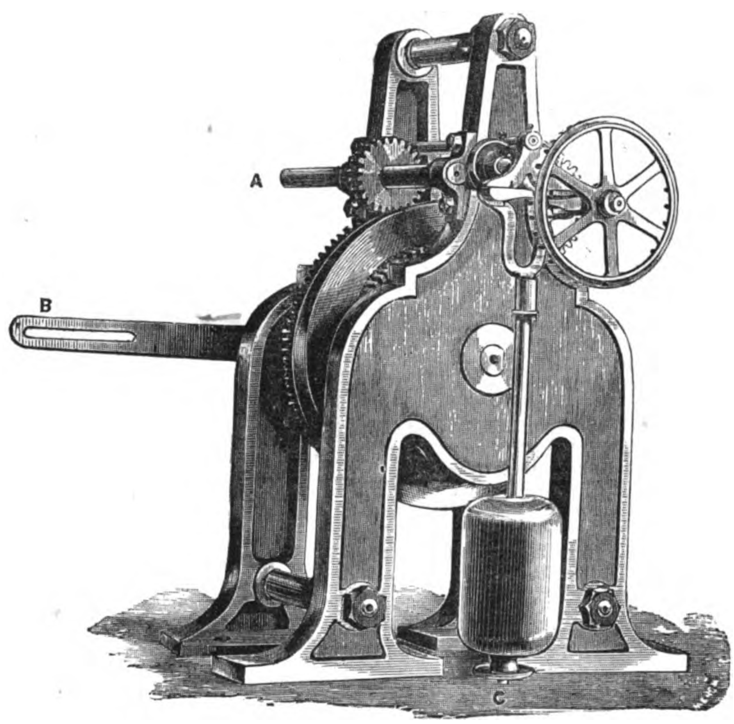


machine may be adapted to make hexagonal or octagonal nuts at one end and square nuts at the other. If the furnace is so arranged that the feeder can heat a sufficient length of his bar at a time, he can form and cut off several nuts at one heat, in which case more than one finisher will be required for each feeder in order to finish the nuts off without reheating as quickly as the machine can produce them.

Our engraving represents at fig. 1 a side elevation, at fig. 2 an end view, and at fig. 3 a plan of Mr. Brierley's machine as arranged in the double-acting form for making hexagonal nuts at one end and square ones at the other. *a a* is the bed of the machine; *b b**, the fixed headstocks; and *c c*, the moving headstock, which works on V slides on the bed as seen at fig. 2. The under side of the moving headstock is formed with two jaws *c* c** (see dotted lines in fig. 1), between which works an eccentric *d d*, keyed fast on the main driving shaft *e e*, which latter is driven with a slow motion by means of the spur wheel and pinion *f f* from the first motion shaft *g g*, which is provided with a flywheel *h h* and speed pulleys *i i*. Attached to the moving headstock at the left-hand side of the machine, fig. 3, is a die or swage *k*, its counterpart *k** being attached to the fixed headstock *b*, and provided with a stop *l*. This die, when the end of a heated bar is placed against the stop *l*, indents the edges of the bar and forms the four angular sides of an hexagonal nut, also partially forming two sides of the next nut. As the headstock recedes, the bar is then withdrawn and placed on edge between the compound tool *n n* and its counterpart *o o*. This tool (as seen enlarged in the detached view, fig. 4) is so formed that, on the return of the headstock, it squeezes or flattens the nut and snaps the edges at the same time that it punches the hole through the centre and cuts the nut off the end of the bar. As the headstock again recedes, the claws *p p* draw the nut off the punch, and the operator proceeds as before. At the right-hand end of the machine, which is arranged for making square nuts, only one tool and its counterpart will be required. The tool consists of one punch *q* and shear and cutter *r*, the counterpart attached to the fixed headstock *b** consisting of a block *s* with a hole in the centre corresponding with the punch; one edge of the block acting as the other blade of the shears; *t t* is the claw for removing the nut from the punch, and *u u* is the adjustable stop against which the end of the bar is held, and which determines the length of the piece cut off. The whole of the tools and counterparts are changeable and adjustable for different forms and sizes of nuts, and the fixed headstocks are also capable of adjustment by means of hand wheels and screws *v v*.

CHRONOMETRICAL REGULATOR.

BY MESSRS. J. BAILEY AND CO.



THE CHRONOMETRICAL REGULATOR.

IN the annexed engraving we give a perspective view of Messrs. Maynard and Grimes' chronometrical regulator for steam engines, which we found at the Manchester Show. It was there exhibited by Messrs. J. Bailey and Co., of the Albion Works, Salford, who are the manufacturers of the apparatus. In this machine the regulator is a pendulum, which, in a most simple manner, is actuated by the engine, and in connection with it is a lever, which maintains a perfectly fixed position so long as the speed of the engine is exactly uniform with the strokes of the pendulum. This lever is connected to the throttle valve or starting gear in combination with any ordinary governor, and the moment the engine varies, by the friction of a stroke from the pendulum, the lever immediately acts upon the valve and prevents further irregularity. The steam engine, by means of this invention, is under as perfect a control as a good clock or watch, and it will perform with

the same regularity; indeed, so exact must the number of strokes of an engine be per day, that when the chronometrical regulator is once set, there cannot be more variation than there is in the performance of a well-regulated clock; hence its name. The importance of regular speed does not require to be enforced; when machines are suddenly stopped, the speed acquired by the engine has often resulted in serious accidents, and always in loss of steam, irregular production, and great wear and tear of the driving gear.

In our engraving, A is the wheel driven by the engine shaft, B the differential lever, which is raised or depressed the moment the engine increases or decreases in speed, and this is done in exact proportion to the increase or decrease; C is the regulating screw of the pendulum, by which the speed of the engine may be adjusted, increased, or diminished. The principle of the chronometrical regulator being a pendulum, it is consequently unvarying in speed, and should the engine vary, either from a change in the power required to be driven, or from any alteration in the pressure of the steam, the lever B at once rises or falls as required, therefore so long as the engine revolves at its proper speed the lever maintains a fixed position. But should any change occur to alter its relative speed, the lever changes its position accordingly, until the speed of the engine is again uniform with the pendulum. As will be seen, the action of the ordinary or ball governor, at the other end of the combination lever, in rising or falling with any variation in the speed of the engine, is almost the same as with the chronometrical regulator, but the effect of the combination of the two is as follows:—As already explained, the lever B, in rising or falling, as required, not only checks the engine by its own action, but at the same time gives to the ordinary governor balls a changeable fulcrum on which they act, and whereby they are always ready to assist the chronometrical regulator under all circumstances, whether the engine is fully or partially loaded, or whether the pressure of the steam is high or low, the only provision being that there shall be steam of sufficient pressure to drive the engine at the required speed; and, however much higher the pressure may be got, or however much weight may be taken off, even down to the empty engine, the speed of the same will be unchanged, and it will work as steadily and with as complete safety as when fully loaded. To put the explanation in a simple form, suppose the chronometrical regulator to be a clock, and the engine engaged in winding it up the regulator or clock having the lever in lieu of weight; should the engine wind it up faster or slower than it can go by virtue of the length of its pendulum, the difference is at once communicated to the throttle valve. The consequence is that, although more steam may be created than is required, or the machinery may be suddenly thrown off, the engine will still perform its duty regularly, and with scarcely any perceptible variation. This invention is of importance to all users of steam power, and its merits entitle it to take a leading position amongst steam governors.

We may add that Messrs. Bailey and Co. have put up these regulators with very satisfactory results at Mr. Hadfield's cotton mills, at Oldham, also at the flax mills of Messrs. Marshall, at Leeds. Others are at work in various parts of the country, and the experiments with them show that very heavy machinery may be suddenly stopped with scarcely any perceptible variation of the speed of the engine. Indeed, so exactly are the revolutions governed that the makers inform us that with or without the load their number is the same taking any five minutes either way.

STEAM FIRE ENGINE FOR THE CITY OF HAMBURG.

THIS engine, constructed by Shand, Mason, and Co., was tried on Wednesday last, at the Grand Surrey Canal, in the presence of a number of eminent engineers and other gentlemen connected with and interested in fire engines and fire brigades. It is the first this firm have made of their newly patented equilibrium steam fire engines, for which a silver medal was awarded at the Agricultural Show held at Edinburgh, and which has since been tried in public at various provincial towns. The general arrangements of the engine are the same as in their engines used by the Metropolitan Fire Brigade. The forepart of the carriage is reserved to carry the firemen, and the hose and implements. The boiler, with the fire engine works fixed to it, is placed close to the hind axle; the whole, mounted on springs and high wheels, is drawn by a pair of horses at great speed. The boiler, by a novel arrangement of inclined water-tubes, combines the greatest rapidity in generating steam with economy of fuel, and is extremely simple in construction. We are informed that 100lb. pressure of steam has been frequently raised from cold water in 6min. 40sec.

The engine consists of a set of treble pumps, an arrangement found by long experience to be the most perfect for raising water under pressure. They are worked directly by a corresponding set of treble steam cylinders, the whole being fixed to the boiler, and forming a very compact and equable steam fire engine. The flow of water through the hose and suction pipe is perfectly uniform, producing a jet as steady as those obtained by pressure from gravitation, and avoiding all shocks to the engine. All present were highly gratified with the rapidity with which the steam was raised, and the manner in which it was increased after the engine was set to work, and maintained during the trial, and the perfectly smooth and quiet working of the engine.

The following are the details of the experiments:—The materials for the fire having been laid, and the boiler supplied with cold water, steam was raised to a pressure of 100lb. to the square inch in 7min. and 4sec. The engine was then started with two jets 10-16ths and 12-16ths of an inch in diameter, afterwards with four jets, being two each 10-16ths and 12-16ths of an inch in diameter, throwing the water to a height of 120ft. Afterwards a jet oflso a diameter was thrown to a height of 180ft., a con- jet of 1½in. to over 100ft. The experiments king cluded with one of 1¾in., the engine wor eam throughout with the greatest regularity, the st being generated so freely that the door of the ur- nace was open a greater part of t time.

AN IRON TANK SHIP.

AN iron tank molasses brig called the "Novelty" lately returned in safety to Boston, U.S., with a cargo of molasses in bulk. The event was a leading theme of conversation in commercial circles. The "Novelty" was built at the Atlantic Works, East Boston, and was fitted with square iron tanks to carry molasses in bulk. She had her tanks filled with water when she left Boston for Cuba, by way of experiment, to see how she would work with a liquid cargo, and also to test the tanks. On her arrival at Matanzas, her tanks were pumped out in a day, and the vessel was then ready to receive cargo, which she took on board at the rate of 200 hogsheads per day. The cargo of the "Novelty" consists of 84,075 gallons, which was pumped by steam power from the vessel into pipes connecting with an iron tank at the Oxnard Sugar Refinery. It is calculated that when the cargo is all ready at the point of shipment it will require only four days to load her when it is received from lighters, and, under favourable conditions, the round voyage can be performed in thirty days. The saving by the use of tanks is estimated at about 2,000dols. on the cargo of the "Novelty." The success of this experiment is due to the enterprising firm of Messrs. Nash, Spaulding, and Co., of Boston, who have persevered against many obstacles before reaching the present successful termination of their efforts. The greatest difficulty to overcome was to allow for fermentation, which is usually equal to 10 per cent. To ensure safety it was necessary to keep the tanks full, or otherwise the rolling of the vessel would destroy them by the swashing of the molasses; so over each tank a turret was constructed, holding about 12 per cent. of the cargo, and when the article was in a fermented state it would naturally rise to the turret, a hole in it being made for the purpose, and, when it subsided, it would fall. Thus, by having molasses in sufficient quantity in the turret, it ensured a full measure for the tank. This successful experiment is likely to revolutionise the carrying trade of molasses.

The "Novelty," however, is by no means a novelty in tank shipbuilding, that feature being confined to the turret, which is an excellent idea. Twenty years since, a tank vessel named the "Cornelia" was engaged in the tar trade, carrying that article from port to port in bulk. At the present time, the "Retriever," a tank vessel of 52,000 gallons holding capacity, is running between the Patent Fuel Company's Works at Deptford and Swansea, Liverpool, and other ports. Her cargo is tar, and she is loaded and unloaded with the greatest rapidity by means of an air pump and vacuum apparatus. The "Retriever," it will be remembered, is the first vessel which was successfully worked in England with liquid fuel furnaces, which are upon Dorsett's system.

A NUMBER of metal images, supposed to be upwards of 800 years old, and to be Hindoo idols, have been dug up in the Fort of Gwalior.

(*Continued from page* 153.)

cution, grants him the exclusive right of practising it, or of authorising others to do so, for a limited number of years, in consideration of his making a full and sufficient description of the same. Unfortunately, this simple and equitable theory of the patent system is very imperfectly carried out, and is beset by various objectionable practices which render a patent sometimes an impediment to, rather than a furtherance of, applied science, and sometimes involve the author of an invention in endless legal contentions and disaster, instead of procuring for him the intended reward. These evils are so great and palpable that many persons, including men of undoubted sincerity and sound judgment on most subjects, advocate the entire abolition of the patent laws. They argue that the desire to publish the results of our mental labour suffices to ensure to the commonwealth the possession of all new discoveries or inventions, and that justice might be done to meritorious inventors by giving them national rewards.

This argument may hold good as regards a scientific discovery, where the labour bestowed is purely mental, and carries with it the pleasurable excitement peculiar to the exercise and advancement of science on the part of the devotee; but a practical invention has to be regarded as the result of a first conception, elaborated by experiments, and their application to existing processes in the face of practical difficulties, of prejudice, and of various discouragements, involving also great expenditure of time and money, which no man can well afford to give away; nor can men of merit be expected to advocate their cause before the national tribunal of rewards, where, at best, only very narrow and imperfect views of the ultimate importance of a new invention would be taken, not to speak of the favouritism to which the doors would be thrown open. Practical men would undoubtedly prefer either to exercise their inventions in secret, where that is possible, or to desist from following up their ideas to the point of their practical realisation. If we review the progress of the technical arts of our time, we may trace important practical inventions almost without exception to the Patent Office. In cases where the inventor of a machine or process happened to belong to a nation without an efficient patent law, we find that he readily transferred the scene of his activity to the country offering him the greatest encouragement, there to swell the ranks of intelligent workers. Whether we look upon the powerful appliances that fashion shapeless masses of iron and steel into railway wheels or axles, or into the more delicate parts of machinery, whether we look upon the complex machinery in our cotton factories, our print works, and paper mills, or into a Birmingham manufactory, where steel pens, buttons, pins, buckles, screws, pencil cases, and other objects of general utility are produced by carefully elaborated machinery at an extremely low cost; or whether we look upon our agricultural machinery, by which England is enabled to compete, without protection, against the Russian or Danubian agriculturist, with cheap labour and cheap land to back him, in nearly all cases we find that the machine has been designed and elaborated in its details by a patentee who did not rest satisfied till he had persuaded the manufacturers to adopt the same, and had removed all their real or imaginary objections to the innovation. We also find that the knowledge of its construction reaches the public directly or indirectly through the Patent Office, thus enlarging the basis for further inventive progress.

The greatest illustration of the beneficial working of the patent laws was supplied, in my opinion, by James Watt when, just about a hundred years ago, he patented his invention of a hot working cylinder and separate steam engine condenser. After years of contest against those adverse circumstances that beset every important innovation, James Watt, with failing health and scanty means, was only upheld in his struggle by the deep conviction of the ultimate triumph of his cause. This conviction gave him confidence to enlist the cooperation of a second capitalist, after the first had failed him, and for asking for an extension of his declining patent. Without this opportune help Watt could not have succeeded to mature his invention. He would, in all probability, have relapsed into the mere instrument maker, with broken health and broken heart; and the invention of the steam engine would not only have been retarded for a generation or two, but its final progress would have been based probably upon the coarser conceptions of Papin, Savory, and Newcomen.

It can easily be shown that the perfect conception of the physical nature of steam, which dwelt like a heaven-born inspiration in Watt's mind, was neither understood by his contemporaries, nor by his followers, up to very recent times, nor can it be gathered from Watt's imperfect specification. James Watt was not satisfied to exclude the condensing water from his working cylinder and to surround the same by non-conducting substances, but he placed between the cylinder and the non-conducting envelope a source of heat in the form of a steam-jacket filled with steam, at a pressure somewhat superior to that of the working steam. His successors have not only discarded the steam-jacket, and even condemned it on the superficial plea that the jacket presented a larger and hotter surface for loss by radiation than the cylinder, but expansive working was actually rejected by some of them on the ground that no practical advantage could be obtained by it. The modern engine, notwithstanding our perfected means of construction, had, in fact, degenerated in many instances into a virtual steam meter, constructed apparently with a view of emptying the boiler in the shortest possible space of time. It is only during the last twenty years that the subtle action of saturated steam (in condensing upon the sides of the cylinder when under pressure, and of re-evaporating when the pressure is relieved toward the end of each stroke) has been again recognised and insisted upon by Lechatelier and others, who have shown the necessity of a slightly superheated cylinder in order to realise the expansive force of steam. The result has been a reduction in the consumption of fuel in our best marine engines from 6lb. or 8lb. to below 3lb. per gross indicated horse-power.

It is a hopeful circumstance that during the next session of Parliament the whole question of the patent laws is likely to be inquired into by a special committee, who, it is to be hoped, will act decidedly in the general interest without being influenced by special claims. They will have it in their power to render the Patent Office an educational institution of the highest order.

In viewing the latest achievements of engineering science two works strike the imagination chiefly by their exceeding magnitude, and by the influence they are likely to exercise upon the traffic of the world. The first of these is the great Pacific Railway, which, in passing through vast regions hitherto inaccessible to civilised man, and over formidable mountain chains, joins California with the Atlantic states of the great American republic. The second is the Suez shipping canal, which, notwithstanding adverse prognostications and serious difficulties, will be opened very shortly to the commerce of the world. These works must greatly extend the range of commercial enterprise in the North Pacific and the Indian Seas. The new waterway to India will, owing to the difficult navigation of the Red Sea, be in effect only available for ships propelled by steam, and will give a stimulus to that branch of engineering.

Telegraph communication with America has been rendered more secure against interruption by the successful submersion of the French Trans-atlantic cable. On the other hand, telegraphic communication with India still remains in a very unsatisfactory condition, owing to imperfect lines and divided administration. To supply a remedy for this public evil the Indo-European Telegraph Company will shortly open its special lines for Indian correspondence. In northern Russia the construction of a land line is far advanced to connect St. Petersburg with the mouth of the Amoor River, on completion of which only a submarine link between the Amoor and San Francisco will be wanting to complete the telegraphic girdle round the earth. With these great highways of speech once established a network of submarine and aerial wires will soon follow to bind all inhabited portions of our globe together into a closer community of interests, which, if followed up by steam communication by land and by sea, will open out a great and meritorious field for the activity of the civil and mechanical engineer.

But while great works have to be carried out in distant parts still more remains to be accomplished nearer home. The railway of to-day has not only taken the place of high roads and canals for the transmission of goods and passengers between our great centres of industry and population, but is already superseding bye-roads leading to places of inferior importance; it competes with the mule in carrying minerals over mountain passes, and with the omnibus in our great cities. If a river cannot be spanned by a bridge without hindering navigation a tunnel is forthwith in contemplation, or, if that should not be practicable, the transit of trains is yet accomplished by the establishment of a large steam ferry.

It is one of the questions of the day to decide by which plan the British Channel should be crossed, to relieve the unfortunate traveller to the conti nent of the exceeding discomfort and delay inseparable from the existing most imperfect arrangements. Considering that this question has now been taken up by some of our leading engineers, and is also entertained by the two interested Governments, we may look forward to its speedy and satisfactory solution.

So long as the attention of railway engineers was confined to the construction of main lines it was necessary for them to provide for a heavy traffic and high speeds, and these desiderata are best met by a level permanent way, by easy curves and heavy rails of the strongest possible materials, namely, cast steel; but, in extending the system to the corners of the earth, cheapness of construction and maintenance, for a moderate speed and a moderate amount of traffic, become a matter of necessity. Instead of plunging through hill and mountain, and of crossing and recrossing rivers by a series of monumental works, the modern railway passes in zigzag up the steep incline, and conforms to the windings of the narrow gorge; it can only be worked by light rolling stock of flexible construction, furnished with increased power of adhesion and great brake power. Yet by the aid of the electric telegraph, in regulating the progress of each train, the number of trains may be so increased as to produce, nevertheless, a large aggregate of traffic; and it is held by some that our trunk lines even would be worked more advantageously by light rolling stock.

The brake power on several of the French and Spanish railways has been greatly increased by an ingenious arrangement conceived by M. Lechatelier, of applying what has been termed "Contre vapour" to the engine, converting it for the time being into a pump, forcing steam and water into the boiler.

While the extension of communication occupies the attention of, perhaps, the greater number of our engineers, others are engaged upon weapons of offensive and defensive warfare. We have scarcely recovered our wonder at the terrific destruction dealt by the Armstrong gun, the Whitworth bolt, or the steel barrel consolidated under Krupp's gigantic steam hammer, when we hear of a shield of such solidity and toughness as to bid defiance to them all. A larger gun or a hard bolt by Palliser or Grüson is the successful answer to this challenge; when again defensive plating, of greater tenacity to absorb the power residing in the shot, or of such imposing weight and hardness combined as to resist the projectile absolutely (causing it to be broken up by the force residing within itself) is brought forward.

The ram of war, with heavy iron sides, which a few years since was thought the most formidable, as it certainly was the most costly, weapon ever devised, is already being superseded by vessels of the "Captain" type, as designed by Captain Coles, and ably carried out by Laird Brothers, with turrets (armed with guns of gigantic power) that resist the heaviest firing, both on account of their extraordinary thickness and of the angular direction in which the shot is likely to strike.

By an ingenious device Captain Moncrieff lowers his gun upon its rocking carriage after firing, and thereby does away with embrasures (the weak places in protecting works), while at the same time he gains the advantage of re-loading his gun in comparative safety. It is presumed that in thus raising formidable engines of offensive and defensive warfare the civilised nations of the earth will pause before putting them into earnest operation, but if they should do so it is consolatory to think that they could not work them for long without effecting the total exhaustion of their treasuries, already drained to the utmost in their construction.

While science and mechanical skill combine to produce these wondrous results the germs of further and still greater achievements are matured in our mechanical workshops, in our forges, and in our metallurgical smelting works; it is there that the materials of construction are prepared, refined, and put into such forms as to render greater and still greater ends attainable. Here a great revolution of our constructive art has been prepared by the production, in large quantities and at moderate cost, of a material of more than twice the strength of iron, which, instead of being fibrous, has its full strength in every direction, and which can be modulated to every degree of ductility, approaching the hardness of the diamond on the one hand and the proverbial toughness of leather on the other. To call this material cast steel seems to attribute to it brittleness and uncertainty of temper, which, however, are by no means its necessary characteristics. This new material, as prepared for constructive purposes, may indeed be both hard and tough, as is illustrated by the hard steel rope that has so materially contributed to the practical success of steam ploughing.

Machinery steel has gradually come into use since about 1850, when Krupp, of Essen, commenced to supply large ingots that were shaped into railway tyres, axles, cannon, &c., by melting steel in halls containing hundreds of melting crucibles. The Bessemer process, in dispensing with the process of puddling, and in utilising the carbon contained in the pig iron to effect the fusion of the final metal, has given a vast extension to the application of cast steel for railway bars, tyres, boiler plates, &c. This process is limited, however, in its application to superior brands of pig iron, containing much carbon and no sulphur or phosphorus, which latter impurities are so destructive to the quality of steel. The puddling process has still, unless the process of decarburisation of Mr. Heaton takes its place, to be resorted to, to purify these inferior pig irons, which constitute the bulk of our productions; and the puddled iron cannot be brought to the condition of cast steel except through the process of fusion. This is accomplished successfully in masses of from three to five tons on the open bed of a regenerative furnace at the Landore Siemens Steel Works, and at other places. At the same works cast steel is also produced, to a limited extent as yet, from iron ore, which, being operated upon in large masses, is reduced to the metallic state and liquefied by the aid of a certain proportion of pig metal. The regenerative gas furnace—the application of which to glass houses, to forges, &c., has made considerable progress—is unquestionably well suited for this operation, because it combines an intensity of heat, limited only by the point of fusion by the most refractory material, with extreme mildness of draught and chemical neutrality of flame.

These and other processes of recent origin tend toward the production, at a comparatively cheap rate, of a very high class material that must shortly supersede iron for almost all structural purposes. As yet engineers hesitate, and very properly so, to construct their bridges, their vessels, and their rolling stock of the material produced by these processes, because no exhaustive experiments have been published as yet fixing the limit to which they may safely be loaded in extension, in compression, and in torsion, and because as yet no sufficient information has been obtained regarding the tests by which their quality can best be ascertained. This great want is in a fair way of being supplied by the experimental researches that have been carried on for some time at her Majesty's dockyards at Woolwich under a committee appointed for that purpose by the Institution of Civil Engineers. I have also the pleasure to announce an elaborate report by Mr. Wm. Fairbairn on this subject. In the meantime excellent service has been rendered by Mr. Kirkaldy in giving us, in a perfectly reliable manner, the resisting power and ductility of any sample of material which we wish to submit to his tests. The results of Mr. Whitworth's experiments tending to render the hammer and the rolls obsolete by forcing cast steel, while in a semi-fluid state, into strong iron moulds by hydraulic pressure, are looked upon with great interest. But, assuming that the new building material has been reduced to the utmost degree of uniformity and cheapness, and that its limits of strength are fully ascertained, there remains still the task for the civil and mechanical engineer to prepare designs suitable for the development of its peculiar qualities. If in constructing a girder, for example, a design were to be adopted that had been worked out for iron, and if all the scantlings were simply reduced in the inverse proportion of the absolute and relative strength of the new material, as compared with iron, such a girder would assuredly collapse when the test weight was applied, for the simple reason that the reduced sectional area of each part, in proportion to its length, would be insufficient to give stiffness. You might as well almost take a design for a wooden structure, and carry it out in iron by simply reducing the section of each part. The advantages of using the stronger material become most apparent if applied, for instance, to large bridges, where the principal

strain upon each part is produced by the weight of the structure itself, for, supposing that the new material can be safely weighted to double the bearing strain of iron, and that the weight of the structure were reduced by one-half accordingly, there would still remain a large excess of available strength in consequence of the reduced total weight, and this would justify a further reduction of the amount of the material employed. In constructing works in foreign parts the reduced cost of carriage furnishes also a powerful argument in favour of the stronger material, although its first cost per ton might largely exceed that of iron.

The inquiries of the Royal Coal Commission into the extent and management of the coal fields appear to be re-assuring as regards the danger of their becoming soon exhausted; nevertheless, the importance of economising these precious deposits in the production of steam power, in metallurgical operations, and in domestic use, can hardly be over-estimated. The calorific power residing in a pound of coal of a given analysis can now be accurately expressed in units of heat, which again are represented by equivalent units of force or of chemical action; therefore, if we ascertain the consumption of coal of a steam engine, or of a furnace employed in metallurgical operations, we are able to tell by the light of physical science what proportion of the heat of combustion is utilised and what proportion is lost. Having arrived at this point we can also trace the channels through which loss takes place, and in diminishing these by judicious improvement we shall more and more approach those standards of ultimate perfection which we can never reach, but which we should, nevertheless, keep steadfastly before our eyes. Thus, a pound of ordinary coal is capable of producing 12,000 Fahrenheit units of heat, which equal 2,240,000 foot-pounds, or units of force; whereas the very best performances o our pumping engines do not exceed the limit of 1,000,000 foot-pounds of force per pound of coal consumed. In like manner 1lb. of coal should be capable of heating 33lb. of iron to the welding point of (say) 3,000deg. Fah., whereas, in an ordinary furnace, not 2lb. of iron are so heated with 1lb. of coal. These figures serve to show the great field for further improvement that lays yet before us. Although heat may be said to be the moving principle by which all things in nature are accomplished, an excess of it is not only hurtful to some of our processes, such as brewing, and destructive to our nutriments, but to those living in hot climates or sitting in crowded rooms an excess of temperature is fully as great a source of discomfort as excessive cold can be. Why, then, may I ask, should we not resort to refrigeration in summer as well as to calorification in winter if it can be shown that the one can be done at nearly the same cost as the other? So long as we rely for refrigeration upon our ice cellars, or upon importation of ice from distant parts, we shall have to look upon refrigeration as a costly luxury only; but by the use of properly-constructed machines it will be possible, I believe, to produce refrigeration at an extremely moderate expenditure of fuel and labour. A machine has already been constructed capable of producing 9lb. of ice, or its equivalent, for 1lb. of coal; whereas the equivalent values of positive heat developed in the combustion of 1lb. of coal, and of negative heat residing in 1lb. of ice, is about as 12,000 to 170, or as one to seventy. This result already justifies the employment of refrigerating machines upon a large scale, but it is hard to say what practical results may yet be reached with an improved machine on strictly dynamical principles, because such a machine seems not tied in its results to any definite theoretical limits. In changing, for example, a pound of water from the liquid into the gaseous state, a given number of units of heat are required that may be produced by combustion of coal or by the expenditure of force, but in changing the same pound of water into ice, heat is not lost but gained in the operation, which heat must be traceable to another part of the machine, either as sensible heat or as developed force. It would lead me too far to enter at present into particulars on this question, which is one not without interest for the physicist and the mechanical engineer.

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the Mechanics' Magazine. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, Mechanics' Magazine Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the Mechanics' Magazine, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Naval, Military, and Gunnery Items.

The "City of Paris," time from Queenstown to Halifax, with Prince Arthur on board, was six days twenty-one hours and a half; or, adding difference of time, at the rate of thirteen and a half knots or fifteen and a half miles per hour.

The old buildings in the fort of Agra, some of the finest specimens of Mahommedan architecture in the country, are to be put in repairs. Some of them have already suffered considerably from the inroads of time and the mischievous propensities of visitors.

In view of the forthcoming opening of the Suez Canal, the Trieste Chamber of Commerce have granted, upon the urgent solicitation of a deputation from the Bourse of that town, permission for a line of steamships to be established and to be subsidised by the State, to run between Trieste and Bombay, via the Suez Canal.

The "Kron Prinz," Captain Werner, iron-plated frigate, belonging to the Prussian navy, went out of Portsmouth harbour on Saturday morning, after having had her hull, below the high water line, cleaned and covered with five different anti-fouling compositions, for the purpose of testing their respective merits. It had been intended to make a trial of her speed at the measured mile in Stokes Bay, but the foremost stokehole having been filled with surplus coal, steam could not be got up in the foremost boilers, and the trial was, therefore, abandoned. She anchored for a short time at Spithead, and Captain Werner and officers visited the "Monarch," iron-plated turret ship. The "Kron Prinz" afterwards left for Kiel.

The interesting ceremony of "trooping the colours" took place at the camp at Aldershott on Monday morning. The troops, composing the Guards and picquets for divisional duty, assembled in the south camp general parade ground at 9·30., and were formed up in eight divisions, under the direction of the brigade major on duty, Captain Brett. At ten o'clock, the general officer on duty, Major-General Lysons, C.B., came on the ground, when the ceremony was at once commenced. After the colours had been trooped the troops gave a general salute, and marched past General Lysons. The Guards were then formed, and marched off to their respective posts by the field officer on duty, Major Montgomery, 2nd battalion 13th Light Infantry.

Major Fosberry, V.C., of the Bengal Staff Corps, who has made several improvements upon the Montigny gun, will have a trial with the weapon in a few days, in competition with other guns, and which is expected to produce most wonderful effects. Major Fosberry is sanguine that he can, at 1,000 yards distance and upwards, strike an object of small dimensions with certainty, and so annoy an enemy in advancing as to cause him fearful loss. When it is considered that 370 rifle-bullets can be discharged from the "mitrailleur" in a minute, the destruction caused by such a terrific fire upon an opposing force would create sad havoc in the ranks, and must ultimately lead to an alteration in the present tactics of war.

Her Majesty's Government have awarded a gold medal to Monsieur Louis Adolphe Bernard, and a silver medal to M. Thadie Legros, for their brave and humane conduct on the occasion of the wreck of the schooner "Gemini," of Hull, near Fecamp, on March 19, 1869. The master, his two children, and a seaman were drowned soon after the "Gemini" was stranded, and the remainder of the crew (four in number) were saved mainly through the exertions of the above two men, assisted by two others, named Oscar Bracklin and Alfred Benard, to whom pecuniary rewards of £2 each have been awarded. M. Louis A. Bernard is reported to have most particularly risked his life on the occasion, and Thadie Legros also risked his life in the very heavy sea that was running, which was beating about broken pieces of the wreck.

The old Portsmouth yacht, which for a long series of years was placed at the disposal of successive admiral superintendents of Portsmouth Dockyard, was taken into No. 6 dock at Portsmouth on Monday to be broken up, it having been determined that in future the admiral superintendent shall not be provided with a craft of this description. It was determined, we believe, that the expenditure for dockyard craft should be reduced, and the late admiral superintendent (Vice-Admiral G. G. Wellesley, C.B.) offered to relinquish the further use of the yacht during his term of office. A strong opinion prevails that a reduction of this kind was so paltry as to have been scarcely worth making, and that an officer occupying the important position of admiral superintendent might fairly have been allowed a privilege which has been extended to the occupants of that office for a great number of years past.

Referring to a paragraph which appeared in our journal a few weeks since, stating that the gun carriages of the "Monarch" worked admirably, a correspondent, who was present at the trials, writes us as follows:—The programme was to fire 40 rounds from one carriage to test it, 20 rounds to be 50lb. charges and 20 rounds to be 67lb. charges. After 20 rounds of 50lb. and 6 of 67lb. charges had been fired, on trying to raise the gun and alter the elevation it could not be moved. The hydraulic was found to be broken and the lifting screws damaged. After some time the hydraulic was repaired, but two hours elapsed before the carriage could be used again. On firing 4 more rounds it was again rendered unserviceable. The other gun in the turret was taken to complete the remaining 10 rounds, after which, on endeavouring to raise the gun, the carriage was found to be damaged and nearly as unserviceable as the other.

Miscellanea.

The gasworks at Peking have come into operation, and the Customs Yamen is lighted from them.

The anthem at Exeter Cathedral on Sunday, when that venerable edifice was crowded with the *savans* attending the Congress of the British Association, was Boyce's—"Oh, where shall wisdom be found!"

The Compagnie des Chantiers de la Seyne have received an order from the Ottoman Government for an iron girder bridge of boats, 6,000ft. in length by 100ft. in width, which is intended to unite Stamboul to Galata.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending August 21, was 5,367. Total number since the opening of the Museum, free daily (May 12, 1858), 1,626,988.

Two gentlemen left Abergavenny on Saturday last, at six a.m., upon a tricycle built on an original plan by one of the party, and arrived at Cheltenham, a distance of about 60 miles, at one p.m. After refreshing they retraced their steps as far as Monmouth, another 40 miles, which they reached about seven in the evening, thus doing the 100 miles, including stoppages, in 13 hours.

A letter from Cairo reports that Sir S. Baker's expedition, 1,700 strong, was to start for the White Nile and Soudan on the 18th inst. Baker Pacha himself, accompanied by Lady Baker and his personal staff, is to follow in a few days. Most of the baggage and stores of the expedition, and a large quantity of merchandise, had already been sent on in advance of the troops.

At the meeting of the Agricultural Society of New South Wales, Sydney, in May last, the first prize, class 205, for portable steam engine suitable to agricultural requirements, was awarded to the 12-horse power portable steam engine of Clayton and Shuttleworth, with enlarged fire box for burning wood, and otherwise adapted for agricultural purposes, to P. N. Russell and Co., Sydney.

The Council of the Working Men's Club and Institute Union have arranged a visit to the Outfalls of the London Sewerage at Crossness Point and Barking Creek, on Saturday, the 28th inst. A special steamer has been engaged. This evening, a lecture explanatory of the whole system of the sewerage of the metropolis will be given by Mr. Hall, at 8 o'clock, in the great room of the Society of Arts.

Arrangements have been made for a visit of the Society of Engineers to the new works of the Chartered Gas Company, at Beckton, on Friday, September 3, 1869. A special steamer (the "Sibyl") has been engaged for the conveyance of the members to Beckton and back to London Bridge, starting from Westminster Bridge at 12 a.m., and calling at London Bridge at 12·30. Tickets, 4s. each, exclusive of refreshments, are to be had of the secretary, at the office of the society, No. 6, Westminster-chambers, on or before Wednesday next.

The number of visitors to the South Kensington Museum during the week ending August 21, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 17,083; Meyrick and other galleries, 2,723; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 2,051; Meyrick and other galleries, 233; total, 22,090. Average of corresponding week in former years, 12,405. Total from opening of Museum, 8,717,908.

BY the new act, to "kill seeds" by destroying the vital power, or to "dye seeds" by colour, to give them the appearance of another seed, is punishable by a fine of £5 for the first offence, and £50 afterwards, with publication of the offender, at his expense, in newspapers.

IT appears that in 1868 new lines were opened upon the principal Italian lines—the upper Italy, the Roman, the South Italian, and the Calabro-Sicilian to the extent of $258\frac{3}{4}$ miles. To this aggregate the South Italian Railway alone contributed $150\frac{5}{8}$ miles. The average length of line worked by the four companies last year was $3,199\frac{3}{4}$ miles, as compared with $3,068\frac{5}{8}$ in 1867. The traffic appears to have increased last year to the extent of 1·98 per cent. per mile worked, as compared with 1867.

THE Deputy-Keeper of the Public Records reports that the six volumes published in 1868 of the chronicles and memorials of Great Britain and Ireland during the Middle Ages make a total of 92 volumes, and that more than 20,000 copies of these volumes have been sold, and more than 3,000 copies have been presented to home, foreign, and colonial libraries. This great national publication has materially contributed to the assistance of historical enquirers. Nineteen more volumes are now in the press.

THE construction workshops of Belgium appear now to have plenty of employment. Both pig and iron show an upward tendency on the markets of the east of France. One establishment of that district is now constructing twelve new puddling furnaces. The proprietors of two other French works—one belonging to the eastern, and the other to the central group—are also erecting some blast furnaces, from 60ft. to 80ft. in height. Rolled puddled iron from mixed pig has realized £8 12s. per ton in the Haute-Marne; ditto, from coke-made pig, £8 4s. to £8 8s. per ton. A good demand for rough pig has continued in the Meurthe and the Moselle; the forges are also actively employed.

CHILDREN under fourteen, in Connecticut, by a recent law, cannot be employed to labour in any manufacturing establishment, or in any other business, unless each child shall have attended for three months out of the twelve some public or private day school, under the charge of a teacher qualified to instruct in orthography, reading, writing, English grammar, geography, and arithmetic. Any person employing any child under fourteen, contrary to the provisions of this act, is liable to a penalty of 100 dollars for each offence. This law is a revival of the provisions of three months' schooling each year, which were required to be inserted in indentures of apprenticeship. It will be observed that the child must be allowed to attend a day school. In old times a night school was considered sufficient.

THE great railway bridge over the Rhine, near the village of Hamm, a little above Dusseldorf, is progressing rapidly, and will probably be completed before the end of November. The bridge is to consist of four arches, the upper part of which will be made of iron. The ironwork of each arch will weigh 14,000 centners. The bridge is united to the main line on the left bank by a viaduct consisting of fifteen stone arches, but this viaduct does not immediately join the bridge; it is separated from it by a revolving drawbridge, so that the line can be rendered impassable at any moment. On the right bank a fort is being built which will command the whole bridge. The first arch of the great bridge is already completed, and on the 15th the workmen engaged in the undertaking celebrated their success in company with their masters.

A TOTAL quantity of 49,016,585lb. unmanufactured tobacco was imported into the United Kingdom during the past year, 28,708,262lb. of which came from the United States, 648,208lb. from the Hanse Towns, 5,852,258lb. from Holland, 875,044lb. from Greece, 8,502,956lb. from Turkey Proper, 4,748,768lb. from the Philippine Islands, 212,829lb. from Japan, 248,644lb. from Cuba, 2,287,415lb. from New Granada, and 1,937,706lb. from other countries. No unmanufactured tobacco was imported into this country from Uruguay or the countries of the Argentine Confederation in 1867 or 1868, and there is a total diminution of imports in 1868 as compared with the previous year amounting to 8,569,702lb. Comparative statistics indicate an increase of imports from New Granada, the Philippine Islands, and Turkey Proper, and a decrease from the Hanse Towns, the United States, Holland, and Japan.

THE blast furnace proprietors who have adopted one or other of the different methods employed for bringing down the gases report satisfactorily of the result. This with regard to one plant of furnaces is seen in the circumstance that between 250 tons and 300 tons of fresh drawn slack heretofore required in raising the steam for their blowing engines and for heating the blast is now being offered for sale. The concern is that of the Parkfield Iron Company at Wolverhampton. If the practice should be extended throughout the whole of the district, and the proportionate saving equal to that here stated, a large amount of economy will have resulted; for notwithstanding that in some cases the adaptation even of the least expensive method is regarded as costly, still the ultimate saving is very marked. Speaking of this one case in particular, the saving may be put as equal to the developing of 500-horse power out of nothing!

A CLYDESDALE mare was recently drowned and a post mortem examination of her stomach disclosed the following fact. According to the "Glasgow Herald," there were taken from it the following articles, viz.:—6 horse nails broken; 8 round nails, from 1in. to 2in. long; 10 single flooring nails, 24 $1\frac{1}{4}$in. nails, 97 broken nails, various sizes, 35 $1\frac{1}{4}$in. nails, 11 1in. zinc nails, 55 $\frac{3}{8}$-inch to one-inch tack nails, 16 shoe tackets, 8 slate nails, 4 screw nails; the total number of nails was thus 269. There were also four common pins $1\frac{3}{8}$in. long each; one blue bead, one brass button, one pearl button, five metal buttons marked V.M., 25 small pieces of galvanized wire, three copper nail heads, four small metal washers, one hook (of hooks and eyes), one hair pin, one-half of a needle, one small piece of lead, seven pieces of zinc—in all 55 articles; or including the 269, 314 articles weighing 1lb. In addition there were found gravel and sand weighing 2lb. $11\frac{1}{2}$oz.

DURING last week a novel use was made of steam power on the farms of Messrs. Howard, at Bedford. A steam ploughing engine, which is also used for traction purposes, is now employed in drawing waggon trains of corn. Many farmers who use steam power for cultivating the land have thought that if the dormant power in the engine could be used during harvest to facilitate operations in fine weather, they would be able to reduce their stud of horses all the year round, and thus save their keep, amounting from £20 to £25 a horse per annum, besides their first cost. It has now been proved satisfactorily that not only the breaking up of the land, but the seeding or drilling can be done most expeditiously and economically by steam. In utilizing its power at harvest time the missing link has, so to speak, been found, so that on a large farm the few horses kept are used as an auxiliary to steam, instead of employing a greater number with steam as an auxiliary, as is now the general practice.

AMONGST the marvellous array of figures contained in the annual report of the Postmaster-General, there is one set which cannot fail to make heavy draughts on the credulity of the reader. "No less than 13,833 letters were posted during the year without any address, and of these 13,833 letters, 281 were found to contain money to the amount of £6,337." Such a fact as this may well be regarded as amongst the curiosities and incredible things of daily life. But the item is never absent from the Postmaster-General's annual report, and the annual number of letters and amounts of money contained therein are quantities almost as uniform as the results of the operation of any known law, so certain is it that a certain proportion of the whole number of letters posted in a year will be posted without any address, and of this number a certain smaller proportion will contain money to a given amount. It may not, however, be generally known that the fund resulting from this source is annually divided amongst the Post Office employes in part payment of their Life Assurance premiums.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—264, 266
BUILDINGS AND BUILDING MATERIALS—227, 229, 236, 237, 242, 243, 244, 245 252, 274, 282, 283, 287, 293, 296, 297
CHEMISTRY AND PHOTOGRAPHY—None
CULTIVATION OF THE SOIL, including agricultural implements and machines—241, 258, 273
ELECTRICAL APPARATUS.—None
FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—221, 226, 231, 258
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—230, 232, 235, 246, 285
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—220. 224, 233, 259, 265, 267
GENERAL MACHINERY—225, 234, 238, 239, 249, 254, 262 284, 301
LIGHTING, HEATING, AND VENTILATING—276
METALS, including apparatus for their manufacture—219
MISCELLANEOUS—223, 228, 240, 248, 250, 256, 257, 260, 270, 272, 275, 277, 280, 281, 289, 294, 299, 303
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—247, 292, 302
SHIPS AND BOATS, including their fittings—251, 261, 263, 278, 279, 295
STEAM ENGINES—271, 300
WARFARE—None

219 H. H. MURDOCH, Staple Inn, London. *Smelting copper.* Dated January 23, 1869.

This consists in the use of a blast furnace of an improved form, similar to an ordinary ironfounder's cupola furnace, with the exception that a high pressure blast is used and distributed in a zone or belt around the furnace just above the cupola part by means of numerous air passages or tuyeres made through the lining or side of the furnace at an angle to the horizon, instead of a low pressure blast being introduced through a hole, as in the ordinary cupola furnace. The tuyeres are supplied with air by means of an air channel running round the exterior of the furnace and communicating with the said tuyere holes, into which channel air of the required pressure is forced. In smelting or reducing copper regulus according to this invention the regulus is charged into the above described furnace, and the melted regulus is allowed to rise above the tuyeres, and is subjected to the action of the air, which is forced through the said tuyeres into and through the said regulus.—Patent completed.

220 B. MOUNTAIN, T. RICHMOND, and G. DUFFIELD Leeds. *Boot and shoe apparatus.* Dated January 23, 1869.

To the upper side o a bracket (within which revolves the shaft of a vertical cutter) they affix a guard, placed in such a position as partially to encircle the cutter. This guard may be of semicircular form and has a notch cut in the centre, whilst the bottom part (which clips the cutter shaft) is recessed or hollowed out, so that the bottom of the cutter, which is of ordinary construction, is lower than the edge of the bottom of the notch referred to.—Patent completed.

221 J. DINSDALE, Skipton. *Spinning and twisting machinery.* Dated January 23, 1869.

The object is to economise time in the doffing of frames and in again starting them, also to adopt one flyer to the two-fold purpose of spinning and twisting. For these purposes the inventor dispenses with the male and female thread usual, and makes the upper end of the spindle (upon which the flyer rests) of conical formation. He also places a pin on either side or through the same corresponding recesses, and the conical formation in the flyer head admits of its passing the pins. The flyer head is also filed or cut down in a slope on the upper edge on either side of each of the opposite recesses.—Patent abandoned.

223 W. M. WELLING, New York. *Composition like ivory.* Dated January 25, 1869.

The basis of this compound is shellac. The inventor prefers the bleached shellac, and with this he mixes kaolin or impalpable (acetate of lead precipitated by sulphuric acid) or other preparation of lead, to give the proper colour. If the articles require to be light or about the gravity of ivory, but little or no lead may be used, and a larger quantity of kaolin or the impalpable white or pigment may predominate or form the principal ingredient with the shellac, and ivory dust or bone or wood dust may be mixed in with the other materials, to produce the desired quality of material; a small quantity of camphor helps to make the articles combine, and where different colours are required suitable pigments may be introduced.—Patent completed.

224 C. TOUCHEVIEUX, Paris. *Hinges for earrings.* Dated January 25, 1869.

To the back of the ornament, and usually at the lower end thereof, the inventor secures, preferably by solder, a bent arm or rod, the upper end of which is hollow to receive the lower end of a bent rod, the upper end of which forms the hook. The portion entering the hollow or socket has a groove formed on and round it, and to secure the two pieces together the metal of the outer rod is pressed into the groove formed on the inner, so that the top part forming the hook is free to turn, but cannot leave the socket. The other end of the bent portion or hook enters a notch formed at the back of the upper portion of the ornament.—Patent completed.

225 C. B. PARKINSON, A. and J. METCALFE, and W. H. HEALD, Preston, Lancashire. *Spinning mules.* Dated January 25, 1869.

To one end of an ordinary mule carriage is attached a rod. This rod is connected at its other end to a bracket which is fixed to a radius rail. A radius arm, one end of which is fitted to (and works on a centre in) the framing, has attached to it a bowl or pulley which works or runs on the radius wheel. A chain is connected to the radius rail and runs on to the chain drum, and at the lower part of the radius rail is placed a movable bracket forming a cop, nose, peg, or plate.—Patent abandoned.

226 R. G. LOWNDES and M. M. CALLUM, Renfrew *Fabric machinery.* Dated January 25, 1869.

The clamping apparatus consists of a specially formed plate or bar of metal or other material which constitutes the lower jaw of the clamp. On it two or more brackets, each constituting the lower eye or half of a hinge joint, are fixed. The upper half of the clamp consists of a bar somewhat similar to the lower one, and also provided with eyes corresponding to those in the lower bar or plate. By means of a pin or pins passing through these eyes, the two bars or plates constituting the clamping jaws are coupled together. The front part of the jaws is lined with wood, ebonite, metal, or other suitable material, between which the fabric to be stretched, stented, or finished is held. At the back of the bar or plate constituting the lower jaw a vertical stud is situated, on which a movable handle or lever is placed.—Patent completed.

227 C. E. BROOMAN, Fleet-street. *Cocks and valves* Dated January 25, 1868.

This consists of a cylindrical or other shaped case or box, either of metal, wood, porcelain, or other material, formed at one end or both ends with a flange, to which flange the end of a flexible pipe, through which the fluid is free to pass, is secured. One end of another flexible pipe is also connected to the flange of the cylinder. This pipe forms a continuation of the first mentioned pipe; the cylindrical case is furnished with a threaded rod, which passes through it. The inner end of the rod has a plate fitted to it, which, when raised, enters an aperture or chamber in the case. The other end carries a handle or small wheel, by which it may be turned. The plate on the inner end of the threaded rod is caused to press when the handle is turned upon that portion of the pipe which passes through the cylindrical case, whereby the pipe is compressed and the flow of fluid regulated or entirely stopped.—Patent abandoned.

228 W. E. Newton, Chancery-lane. *Sheet metal stamps.* Dated January 25, 1869.

The sheet metal-plate to be worked into a sunken form is placed on and over a die of suitable configuration according to the article to be made, and a holding plate or block (carried by a series of pistons) is brought down to bear on the margin or portion of the sheet metal plate outside of and around the hollow of the die. The sheet metal plate thus held is then subjected to the action of a stamp operated by a central or main piston arranged to work through the holding block to press the sheet metal plate (or portion of it lying within the inner edges of the holding block) into the hollow of the die. The several pistons may be operated either by steam, air, or water, so that the whole apparatus forms what may be termed a steam pneumatic or hydraulic cylinder engine press for shaping forms from sheet metal.—Patent completed.

229 J. Carr, Manchester. *Venetian blind tapes.* Dated January 25, 1869

The inventor uses a jacquard loom and furnishes it with four sets of warps, or warps which may be divided, as is well known, so as to form sheds for more than one web of cloth, and to supply these warps with weft he employs a rising box loom and prefers that it shall be furnished with four shuttles, one for each of the two tapes and one for each of the short strips, although a smaller or larger number may be used, and the arrangement of loom he now employs is that which is known as the marionette. The machinery, however, may be of any arrangement used for similar purposes and the order of making the sheds varied.—Patent completed.

230 A. V. Newton, Patent Office, Chancery-lane. *Grain germinators.* (A communication.) Dated January 25, 1869.

The introduced air rising upwards through a fluid substance gently agitates the same, thereby exposing every part of it to the oxidising action of the air more perfectly and uniformly than in a quiescent state. Where yeast is used, which is more or less uniformly distributed, the mixing will take place more thoroughly by the introduction of air, which also stirs up and revives the yeast; therefore the formation of alcohol will be assisted and otherwise the product materially improved.—Patent completed.

231 E. Hartley, Oldham. *Weaving looms.* Dated January 25, 1869.

The inventor proposes to employ a stop which, when the lathe retreats, acts against a spring, through the medium of which the shuttle is then trapped, but when the lathe begins to move forward, the stop retires from the spring and the shuttle is relieved from pressure. He proposes to use the "stop rod finger" for the spring to act upon, and to employ the usual swell as an intermediate part or to dispense with it.—Patent abandoned

232 H. D. Bowyer, Ripley. *Manufacture of wheaten flour.* Dated January 25, 1869.

The inventor first flattens or crushes the grain without breaking it into pieces, and this he does by passing the grain between smooth metal rollers. In this way he loosens the bran from the other parts of the grain. He then grinds the flattened or crushed grain between stones, when, in consequence of the preliminary flattening or crushing as soon as the stones touch the grain the bran separates in large flakes, and hence little or none of the bran is ground, whereas when the unflattened or uncrushed grain is exposed to the stones in the usual way of grinding a notable quantity of the bran is reduced to powder by the stones, and remaining in the flour discolours it.—Patent completed.

233 R. J. Green, Birmingham. *Collar studs, buttons, &c.* Dated January 25, 1869.

This consists, first, in appending to the front of collar studs or buttons a tongue or depending piece, which when the stud or button is in use lies in front of and holds down the scarf or neck-tie and prevents it from rising above the stud or button. The tongue or depending piece is made capable of being connected to and detached from the stud or button at pleasure, the connection being made by means of a spring snap or depending piece taking into and engaging with a recess or hole in the stud or button, or by other fastening.—Patent completed.

234 J. and S. Roberts, West Bromwich. *Moulds for casting.* Dated January 25, 1869.

The pattern pipe is supported horizontally and accurately fits in an opening in a moulding bed or plate at such a height that exactly one half of the pipe stands above the upper surface of the said moulding bed or plate. Upon this half pattern a half mould is made by ramming sand in a mould box in the usual way. As soon as the half mould is made the pattern is removed therefrom by depressing the said pattern through the opening in the moulding bed or plate below the surface of the said bed or plate, when the half mould formed may be removed from the moulding bed or plate. The pattern is again raised to its original position in the moulding plate and another half mould is made upon it, from which the pattern is removed by depressing it below the moulding plate, as before described.—Patent abandoned.

235 H. W. and R. Lafferty, New Jersey. *Sugar rectifier.* Dated January 25, 1869.

This relates, first, to improvements in the mode of supporting the spindle carrying the drum or basket of a suspended centrifugal draining machine, viz., placing and securing an encircling hollow nut or flanged cap in an inverted position upon said spindle, and receiving and supporting the projecting edge or rim of this nut or cap upon one or more washers in the bottom of an annular oil cup encircling the spindle but secured to and resting upon an independent hanger, bracket, or other supporting device arranged therefor. The spindle thus supported and suspended revolves upon bearings submerged in oil, so that the friction thereof is consequently reduced to the lowest degree.—Patent completed.

236 C. L. Wood, Bishop Auckland, and J. Stockley, Newcastle-on-Tyne. *Plate glass apparatus.* Dated January 26, 1869.

The rods which carry and drive the grinding runners are arranged in the direction of the width of the benches or tables (and as usual in pairs) instead of in the direction of their length as usual, thereby admitting of the use of shorter rods, and consequently of increased speed for the runners.—Patent completed.

237 E. D. Rushton and W. W. Mills, Birmingham. *Window sashes.* Dated January 26, 1869.

In connection with an ordinary sash and on either of its sides, and projecting slightly from the edge thereof, the inventors place a toothed wheel turning in a frame fixed to the said sash. The teeth of these toothed wheels are inclined to their axes, the said wheels somewhat resembling ordinary worm wheels. The teeth of the wheels may, however, be parallel with their axes. Working in slots in the sash are spring clicks or catches which engage with the toothed wheels and prevent their rotation. On either side the sash frame and in the line of the motion of the sash, strips or ribs of vulcanized india-rubber or other similar elastic material are fixed; they make these elastic strips or ribs by preference of a nearly semicircular figure in cross section, the convex side of the strip or rib being situated outwards, and being presented to the projecting parts of the toothed wheels fixed on either side the sash. When the sash provided with the toothed wheels described is in its place in the window frame the toothed wheels compress and flatten the india-rubber strips or ribs By the elasticity of the strips or ribs such an amount of resistance is offered to the toothed wheels as to support the said sash in any position in which it is placed. In order to raise or lower the sash the spring catches described are lifted from the toothed wheels so as to permit them to rotate. They prefer to arrange the handles of the catches so that the disengaging of the catches and the lifting or depressing of the sash are effected at one operation. Or the catches may be geared together in any convenient way so that pressure at one part of the sash may simultaneously release both catches.—Patent completed.

238 J. D. Ellis, Sheffield. *Rolling armour plates.* Dated January 26, 1869.

The inventor builds and heats the pile in the ordinary manner, and having set in motion rolls of a length exceeding the greatest breadth to be given to the armour plate, he introduces the pile and rolls it to and fro until he has obtained the full width of plate required. He then, by means of a turntable, overhead crane, or other suitable apparatus, turns this plate and rolls it in the direction of its length until it has attained the length and thickness originally determined upon.—Patent completed.

239 J. and J. Wilson, York. *Fibre machinery.* Dated January 26, 1869.

On a hollow bar or casing nearly the length of the frame and parallel with the rollers, are a number of lever catches, one opposite each set of rollers. The lever catches work on a pin or stud about midway their length, and the bar or rod carrying them has an internal rod traversing "to and fro," motion being imparted by means of a cam or an eccentric and wheel and a weight; the sliver or roving in its passage from the rollers to the bobbin bears on one end of the catch levers, the weight or tensional strain keeping the catch levers down on their bar or rod.—Patent completed.

240 J. Millar, Cambridge-road. *Envelopes.* Dated January 26, 1869.

The inventor proposes to form the fastening flap of the envelope intended to enclose letters or documents with a series of serrated or corrugated edges, presenting a number of pointed edges or curvilinear projections, which being gummed down, will afford a more secure attachment than can be effected by the ordinary flaps. In some cases, a perforated ornamental device or a perforated monogram may be formed on the extremity of the flap, the edges being made with a series of notches and teeth, whereby, when the flap is secured, any attempt to open the same clandestinely will be exposed by the tearing away of some portions of the flap.—Patent abandoned.

241 J. Wilson, Poppleton. *Straw making.* Dated January 26, 1869.

The machine consists of a series of leather bands (with spaces between each) and cross bands attached to bars at each of its ends, and extending from the feeding hopper and drum to the delivering board. It is actuated by two hangers or rods suspended vertically by means of pivots. The hangers are attached to shoes formed of iron and containing grooves, in which a shaft works provided with an eccentric at each end. The shoes being attached to the delivering board, it is evident that the revolution of the eccentrics will give an oscillating motion to the shoes, hangers, and board, and also to the leather shaker, alternately slackening and tightening each end, the shaker being supported midway from the board by uprights leaving two divisions of the shaker in a position while the machine is at rest.—Patent completed.

242 J. Pickering, Glasgow. *Treating timber.* Dated January 26, 1869.

This consists in applying to the surfaces of the timber to be finished rapidly moving surfaces of grinding or polishing material, such as sandstone, grindstone, emery, in combination with other substances or other suitable abrading materials. The finishing surfaces of the abrading and polishing substances are circular and made to revolve at a high velocity against or upon the surfaces of the timber requiring to be treated by them, the effect of the treatment being that heat is generated by the friction of the abrading surfaces upon the wood, so that the surface of the wood becomes coloured to the required extent, besides being rendered very smooth and polished in a rapid manner.—Patent completed.

243 W. R. Lake, Southampton-buildings. *Ventilators.* (A communication.) Dated January 26, 1869.

The body of the ventilator consists of a wedge-shaped box attached to a supporting frame or diaphragm intended to secure the body to the window. There is an adjustable funnel for adapting the ventilator to double windows, and a perforated shelf for holding a sponge or other porous absorbent. A perforated box for holding charcoal fits closely into the top of the body, but is capable of being removed at pleasure. A sliding valve regulates or cuts off the supply of air, and a foul air escape pipe is used in connection with stoves. When double windows are not used, the adjustable funnel will not be required, and in such cases that part of the invention may be dispensed with.—Patent completed.

244 A. V. Newton, Chancery-lane. *Veneer cutters.* (A communication.) Dated January 26, 1869.

This relates to a novel construction of what is called the "stay log" of a veneer-cutting machine, and which, carrying a log or section of a log, is made to revolve and present as it rotates the log or section to the action of a knife or cutter, so as to cut in curvatures corresponding to the rings of the tree or thereabouts. In this novel construction, the portion of the stay log to which the timber is bolted is rendered adjustable relatively to its journals, so that an eccentric adjustment may be given it to suit logs or log sections of different peripherical or perimetrical curvatures, and to adapt it to avoid cutting from or through defective portions of the log or section, which in having a complete revolution given at each cut affords ample time and opportunity to set or feed up the cutter without stopping or checking the motion of the machinery.—Patent completed.

245 H. Law, Strand. *Metal pipe connectors.* Dated January 26, 1869.

Soft metal pipes have sometimes been connected by expanding the mouths of the two pipes to be brought together by driving a cone into them, and then inserting between the mouths a double cone of metal, consisting of two cones united at their bases, and with a hole passing through them from apex to apex of the size of the waterway of the pipes. Afterwards the mouths of the pipes were drawn together by means of two rings which were placed on the pipes before coning them, and which rings were so formed as to fit the ends of the pipes when coned. The present method is up to this point similar to that described, but formerly the exterior cone rings which draw the parts together have been made each with two lugs, one on either side, and screw bolts passed through the lugs have been used to draw the parts together.—Patent completed.

246 C. Gil, Paris. *Sugar.* Dated January 26, 1869.

The inventor has observed that when limiting the acid to small quantities instead of its being prejudicial it produces great advantages in the colour, taste, and easy draining of the syrup and even by changing it into crystallizable sugar. This observation has led him to employ an acid process, a method of proceeding entirely different from those used in the manufacture of sugar, and permitting him to obtain new and very advantageous results, viz., to produce directly from the beet root juice white manufactured masses having an excellent flavour, and above all giving loaves which drain easily and are perfect, as well as regular results, which cannot be obtained by an alkaline or neutral process.—Patent completed.

247 C. French, Blandford-square. *Communicating in trains.* Dated January 27, 1869.

The inventor employs a length of chain, cord, rope, or wire for each carriage, provided with a spring hook at each end for connecting one length with another, and in order to prevent the slackening or straining of the rope or other communicator upon the carriages approaching or receding from each other, he passes it around pulleys at each end of each carriage. One of such pulleys is carried by an arm, the other being fixed to a plate to which the arm is connected. The arms are each provided with a coupling or pin joint so as to facilitate their connection with each other, and they are connected to the carriages by double pin joints, one being in the contrary direction to the other (or a universal joint may be used) so as to facilitate the passage of the carriages around curves without injuring the connections.—Patent abandoned.

248 C. Mather, Salford. *Singeing apparatus.* Dated January 27, 1869.

This relates to those singeing frames in which the fabric is brought against both sides of the flame, and in which the combustion of the gas is promoted by causing a current of cold air to be drawn towards or through the flame. This current of air is produced by a fan or other equivalent, which exhausts the air out of a slotted tube, and this invention consists in the application of certain parts to the above machines, whereby the results produced by the process of singeing are greatly improved. In carrying out this improvement the inventor applies a doctor or thin blade of metal or a roller with blades against the surface of the fabric that has been singed, and this doctor is adjustable, so as to act with more or less force on the fabric as it passes one guide roller or rail to the other. The effect of the fabric passing over the doctor is to detach the carbonised particles, and when the doctor is placed in a slot in the air tube these particles are carried away by the fan.—Patent completed.

249 T. Reeder, Preston. *Sheet metal rollers.* Dated January 27, 1869.

In carrying out this invention the edges of a plate of sheet metal are first bent over, and then the sheet is formed into a tube or cylinder with the bent edges locking into each other as usual. This tube is then put on a mandrel having a longitudinal groove for the joint; a die of the exact diameter of the finished roller is then drawn over the tube on the mandrel, and the action of this die equalises the irregularities in the thickness of the sheet metal, thereby producing a roller of uniform diameter throughout its length. In some cases more than one die may be drawn over the tube on the mandrel, or the same die may be drawn over more than once, and as the die is of the exact diameter of the finished roller it is evident that the thicker parts of the sheet metal are drawn out and elongated until the metal is of uniform thickness.—Patent completed.

250 J. Gough, Kirby-street, Hatton Garden. *Application of colour to printing surfaces.* Dated January 27, 1869.

This consists in maintaining the necessary supply of ink or colour in the interior of a cylinder, which is suitably mounted on a spindle and free to revolve thereon. It is furnished with openings in its circumference, through which ink or colour from the interior can find its way to the outer surface, which is grooved to allow of the ink or colour spreading. Enough of the outer surface, however, is left between the grooves to give adequate support to a covering of wire gauze or other permeable material or materials, through which the ink or colour can escape or be withdrawn.—Patent abandoned.

251 J. Taylor, Birkenhead. *Ships' propelling apparatus.* Dated January 27, 1869.

The inventor hinges to the sides of the vessel arms or levers, to the ends of which are attached screw propellers worked by means of air or hydraulic engines applied direct thereto, to which the air or water under pressure is conveyed through flexible or jointed pipes, passing from a suitable pumping engine on board over the side of the vessel and down to the engines, or the propellers may be worked by endless chains, ropes, or bands passing over a pitch wheel on the shaft of the propeller and worked from a steam winch, crane, or other engine on deck, arranged to turn on a turntable, so that by lowering the arms or levers with the screw propeller into the water against the side of the ship, and driving the screws by the air or hydraulic engines, or by endless chains, the ship

may be propelled when becalmed. When the screw propellers are not required the arms or levers are raised up out of the water into an upright position and serve as davits or shear legs for raising, lowering, and suspending the ship's boats.—Patent abandoned.

252 T. VAUGHAN, Middlesborough. *Smoke and soot machine.* Dated January 27, 1869.

The inventor collects the smoke or soot found in all chimneys, funnels, or flues, as also in gas and other retort flues, or in any other place where carbonaceous matter is burnt, which smoke (when condensed) or which soot is then subjected to the process of calcining in order to separate therefrom the volatile constituents and sulphurous particles, after which it is ground under edge runners or other suitable apparatus. Or the condensed smoke or soot may previously be sifted, by preference by the action of an air blast, by which the finer particles are carried away into a chamber, leaving the coarser particles behind, which may then be ground.—Patent abandoned.

253 H. BARCROFT, Glen, near Newry, Ireland. *Damask machines.* Dated January 27, 1869.

This consists in the use of a horizontal bar or tumbler stretching across the machine between the rows of hooks and below the grife, and moving on a longitudinal pin or axle bearing at each end in the framework or in a bracket attached to the framework of the machine. The office of the bar or tumbler is to press one row of hooks towards and so as to catch a knife of the grife, and to press the adjoining row of hooks from and so as to avoid a knife of the grife at each pick or throw of the shuttle, thereby producing the twills. The bars or tumblers meet the rows of hooks at an inclination, and are set in motion by a horizontal shaft revolving at right angles to the bars or tumblers in sockets or bushes in the framework of the machine, and furnished with tappets, each of which strikes a snugor or lever attached to the axle or pin of a bar or tumbler, so as to raise the lower side or edge and to depress the higher side or edge of the bar or tumbler. A spring restores the bar or tumbler to its out-of-action inclination as soon as the action of the tappet ceases. The revolving shaft, which carries the tappet, is furnished with a ratchet wheel, such as is hereinafter described, through which it receives the required motion. In order to press only part or parts of a row or rows of the hooks as hereinbefore described the blade of the bar or tumbler between the rows of hooks must be limited in length to the part of the row of hooks desired to be made use of, and the number of bars must be increased to equal the number of such parts. One bar or tumbler may be used alone, or several bars or tumblers may be used simultaneously according to the twill required to be produced. —Patent completed.

254 J. PORTEOUS, Edinburgh, and H GIBSON, Musselborough. *Tobacco machinery.* Dated January 27, 1869.

This consists of a shaft or spindle on which circular flanges, by preference with openings formed in them, are placed, the distances between these flanges being equal to the length of the rolls, which are to be coiled. On the end of the above-mentioned spindle a worm or screw is fitted, and this gears into a worm wheel carried on a stud or cross shaft. To the body of the worm wheel a heart or other shaped cam is fixed, which acts against an antifriction roller carried on a horizontal guide rod, this guide rod being jointed to a lever to which the vibrating action due to the cam is communicated.—Patent abandoned.

256 J. H. JOHNSON, Lincoln's Inn-fields. *Railway keys* (A communication). Dated January 27, 1869.

This relates to an improved construction of the keys or wedges employed in securing or holding the rails of the permanent way of railways, or used in other engineering constructions exposed to the action of the weather, whereby not only are the wedges rendered more durable, but a better and more permanent or tightening is obtained of the rail or other part to which the wedge is applied. According to this invention it is proposed, in lieu of making the keys or wedges entirely of wood as heretofore, which are sure to be destroyed by the blows of the hammer under the constant tightening necessitated by the alternate shrinking and swelling of the wood with the changes of the weather, to construct such keys or wedges partly of metal, say cast iron, and partly of wood, preferring such wood as has been previously treated with a view to its preservation in any well known manner, as, for example, by injection and compression. The main partition of the key or wedge is made of metal, which, receives the blows of the hammer when being driven, and this piece of metal is recessed on one or both sides, or has an opening made through it, into which recesses or opening is inserted a facing or a block of wood, the friction or holding surface or surfaces being of wood, whilst the core or body is of metal. The wooden partitions should, by preference, be rather shorter than the metal portion, in order that the hammer may not come in contact with and destroy the wood in the operation of driving.—Patent completed.

257 J. GIRDWOOD, Edinburgh. *Envelopes and bags.* Dated January 27, 1869.

This consists in making blanks for envelopes or sample bags of various forms impossible to describe unless with reference to drawings.—Patent completed.

258 E. H. PRENTICE, Stowmarket. *Phosphatic manures.* Dated January 27, 1869.

The inventor has found that by the addition of a certain proportion of chloride of ammonium to the phosphatic materials during the action of the sulphuric or other acid thereon, a larger proportion of the phosphate is rendered soluble, and that there is less if any tendency for the soluble phosphate to revert to the insoluble form. Before treating the phosphatic materials the inventor determines by analysis the quantity of sulphuric or other acid required to render the phosphates soluble, as is usually done. The mixing of the acid and the phosphatic materials is then effected by any of the processes commonly employed, and the chloride of ammonium is added either during or after such mixing, or the chloride of ammonium may be incorporated with the phosphatic material before this is mixed with the acid.—Patent abandoned.

259 J. SILMAN, Birmingham. *Shoemakers' sole knives.* Dated January 27, 1869.

This consists in manufacturing the knives as follows:—The inventor forms, by the process of rolling bars of steel having a taper or wedge shape in cross section, a smaller or supplementary wedge being formed near the thin edge of the bar. The bar is plain on one face, but slightly convex near the thin edge, while the other face has near the thin edge of the bar a step or shoulder formed by the supplementary wedge-shaped part described. The bars are cut into pieces of such length that each piece, when bent into the proper shape and its ends welded together, will form one of the said knives. In making the knives from the bars of steel the bars are bent so that the shoulder described shall be in the inside of the knife. In using the knives, the soles as they are cut out rise above the said shoulder, and thus entering a larger part of the knife offers no resistance to the soles afterwards cut.—Patent completed.

260 G. TANGYE, Birmingham. *Copying presses.* Dated January 27, 1869.

The lower platter or surface on which the copying book is placed while a letter is being copied, is supported on two hollow uprights fixed to the base plate of the press, these uprights being connected to the base by joints which permit the uprights and platten to have motion through a small angle in a vertical plane. The said lower platten is connected to the top of the uprights by joints. The upper platten is supported by a screw working in a crosshead, the crosshead being fixed to the tops of two upright rods passing through the hollow uprights carrying the lower platten.—Patent completed.

261 C. LUNGLEY, Greenwich. *Iron work structures.* Dated January 27, 1869.

The objects of this invention are to build in wood and iron and other metal caissons pontoons and other such structures, such as ships and other vessels, and to fit the same with divisions, tanks, and decks, so that the floating capacity of a caisson and pontoon may lift all or nearly all its own weight, and thus save the lifting of the weight of the caisson or pontoon which now has to be lifted in addition to the ship upon it when lifted by hydraulic or other pressure.—Patent completed.

262 A. C. PASS, Bedminster. *Condensing vapour.* Dated January 27, 1869.

The smoke fumes, vapours, or gases to be condensed or purified are drawn, forced, or driven by motive, ductive, or propelling power, through the meshes, interstices, or apertures of a series or arrangement of latticework, sievework, bars, perforated or reticulated material, or other like appliance or contrivance whereby the smoke, fumes, vapours, and gases are divided, and which offer the largest possible wetted, damped, or moistened surface in the smallest possible space for the accomplishment of this object. On or over this lattice work or other above described arrangement, the inventor projects or applies a continuous flow of water, so that the smoke, fumes, vapours, or gases are brought for a sufficiently protracted period into intimate contact with water, which absorbs a large portion of the noxious gases, and also cools the vapours, smoke, gas, or fumes, and charges them with moisture. The cooled and damped smoke, fumes, vapours, or gases are led or pass into a chamber or receptacle in which they deposit the metal, particles, and soot, and the now invisible gases are allowed to escape.—Patent completed.

263 C. W. PETERSEN, Norton Folgate. *Lifeboats, &c.* Dated January 27, 1869.

The inventor constructs lifeboats with a watertight chamber of oval or other form rising from the centre of a deck for the purpose of rendering the boat self-righting in the event of its being capsized by reason of the increased buoyancy obtained at the upper part of the boat by means of the chamber. This chamber, which may be provided with an air shaft or shafts, and with glazed openings for admitting light, may also be applied to steam tugs, pilot boats, and tenders, and to ordinary ships' lifeboats when decked for the purpose above described, and may serve as a saloon cabin, or for other purpose.—Patent abandoned.

264 B. M. MARCHANT, Torrington-square, W.C. *Obtaining power.* Dated January 28, 1869.

This consists in the compression by force pumps in stages of certain gases to be used as a motive power, with or without subsequent heating, so that a pressure is obtained allowing of their most expansive application, the supply being cut off from the cylinder (where this method of applying the power so provided is used) at any desiredly small fraction of the length of the stroke of the piston therein.—Patent completed.

265 W. SPURRIER, Birmingham. *Salt spoons.* Dated January 28, 1869.

The inventor makes the bowls of the spoons of greater thickness and consequent weight of metal than usual, the weight of the bowls being equal to or greater than the weight of the handles of the spoons. When a salt spoon of this kind is placed in the salt cellar, the weight of the bowl causes it to take a safe position therein, and there is no tendency of the spoon to overbalance. He gives this increased strength and weight of metal to the bowl of the spoon by making the blank from which the spoon is to be made of the greatest thickness at that end from which the bowl is to be formed, so that when the blank is raised or fashioned into a spoon in the usual manner, and by the use of the ordinary shaping dies a spoon is produced having a bowl as heavy as or heavier than the handle of the said spoon.—Patent abandoned.

266 W. BROWN and T. H. GARBUTT, Seamur. *Fire-bars.* Dated January 28, 1869.

This consists in constructing fire or furnace bars hollow and perforated in themselves, and thereby allowing of a rapid and free circulation of air through as well as between them, this greatly improving the draught and thereby ensuring the proper and thorough consumption of fuel; also the bar by this means being kept a uniformly low temperature, its fusion, fouling, and breaking is entirely prevented, or nearly so.—Patent completed.

267 R. JONES, Botolph-lane. *Improvements in curing apparatus.* Dated January 28, 1869.

The animal substance to be cured is placed in a suitably sized tank capable of being closed airtight, and which is also supplied with brine or curing matter supplied from a suitable reservoir, and a portion of the liquid is then withdrawn from the interior of the tank, and the animal matters therein, and thereby facilitates the impregnation of the brine or curing matter.—Patent abandoned.

270 R. BLACKBEE, Norfolk-road, Dalston. *An improved pessary.* Dated January 28, 1869.

This consists in so constructing a pessary as that by being shaped in direct reference to the anatomy of the pelvis, it shall possess, from its peculiar construction, a double self-acting spring, that is to say, laterally and transversely.—Patent completed.

271 A. BROWNE, King William-street. *Rotary engines.* Dated January 28, 1869.

Within a hollow fixed cylinder, placed horizontally and formed with closed ends, another but solid cylinder is fitted, so as to be capable of revolving within the fixed cylinder, the two cylinders being formed of such diameters as to leave an annular space between them for the passage of steam across the edge of the aforesaid solid cylinder, and opposite to each other two slits are formed, each communicating with a circular hole formed across and through the said solid cylinder. Into each of the aforesaid slits a flat, side, or piston is fitted steamtight, and the said slides or pistons are kept forced outwards, each by a spring or springs placed in the before-mentioned circular holes.—Patent abandoned.

272 L. P. HEBERT and L. A. MOULIN, Neuilly on-Seine, France. *Letter stamp, &c.* Dated January 28, 1869.

This consists of an ink box of the same shape as the stamp, with a vertical tube at the centre and top thereof. The ink box is formed in two parts or chambers. The upper one contains the ink, and in the lower one a sheet of cork is placed, and a piece of felt in contact therewith. The division plate of the ink box, as also the piece of cork, are pierced with small holes, for the passage of the ink on to the felt.—Patent completed.

273 J. BOX, Southsea House, E.C. *Cleaning wool.* Dated January 28, 1869.

The burr and all other vegetable and ligneous matters in wool or in hair in its raw and unmanufactured state are destroyed by passing into and through the wool or hair a current of chlorhydric acid gas, which gas is produced by the saturation of common salt by dilute sulphuric acid placed over a moderate heat. The wool of sheep and the hair of goats are frequently greatly damaged in value by the burr, which is the seed vessel of a plant common in England and most other parts of the world.—Patent completed.

274 J. EASTERBROOK, J. H. ALLCARD, and A. M. WILD, Sheffield. *Grinding and polishing.* Dated January 28, 1869.

The inventors mount a grindstone emery wheel or other grinder on a revolving axis carried by a suitable frame. The stone or grinder is placed against a face plate at the end of the axis and is there clamped or held in a suitable chuck, so that the flat of the grinder may run truly. Opposite to the grinder is a slide capable of traversing on guides on the frame in a direction parallel with the grinding face. On the face of the slide (which can be set for grinding taper if required) the article to be ground is held by suitable stud jaws or other convenient fastenings.—Patent completed.

275 N. C. SZERELMEY, Pimlico. *Making tarpauling.* Dated January 29, 1869.

The inventor boils in an iron pot 1cwt. of gas tar until the same becomes hard, and at the same time he boils in another iron pot, which is heated by steam, admitted between the pot and a jacket or casing which surrounds it, 14 gallons of Stockholm tar spirit, 10lb. of American rosin, and one gallon of rosin oil. When these ingredients are completely dissolved and mixed, they are drawn, together with the boiled tar, which should be at about the same temperature, into a mixing vat or vessel, and the whole is thoroughly stirred together. When the mixing has been continued for about ten minutes, 2oz. of commercial sulphuric acid is added, and the mixing is continued. This composition is suitable for the preparation of dark coloured tarpauling, and for preserving sail cloth and other fabrics.—Patent completed.

276 G. HAWKSLEY, Caledonian-road. *Ventilators and chimney pots.* Dated January 29, 1869.

These ventilators or pots are formed from a long metal band, say of hoop iron, which the inventor turns into a coil by extending it on one edge more than on the other. He does this by passing the hoop iron between rollers which are set so as to form a taper nip, and the roller may be so formed as simultaneously to give to the iron a curved face. Or, in place of expanding the outer edge of the hoop iron, a similar result may be obtained by corrugating its inner edge. He then takes a cylindrical mandrel of the size of the interior of the ventilator or pot which it is desired to produce, and having in it a number of longitudinal radial grooves equi-distant the one from the other. In these grooves, other flat pieces of hoop iron are placed, having inclined notches in them at equal distances apart from end to end of each piece.—Patent completed.

277 W. M'LEAN, Glasgow. *Printing apparatus.* Dated January 29, 1869.

The machine consists of an upright frame in which the zinc cylinder is carried in bearings. Above the zinc cylinder is a pressure roller. At the side or sides or other convenient part of the frame, the trough or troughs for containing the printing ink is or are placed, and a roller is situated near to it, so that the ink may be carried to the ink distributing rollers, and thence to the zinc cylinder. Damping rollers revolve in contact with the zinc cylinder, and the whole is put in motion by spur or toothed gearing. A lever and adjustable weights are situated either beneath the floor or above the framing of themac hine, and these are so arranged as to force the zinc cylinders with the necessary amount of pressure against the pressure roller, or, in lieu of a lever and weights pressure, screws may be employed.—Patent completed.

278 J. PICKERING, Glasgow. *Propelling ships.* Dated January 29, 1869.

The injectors or ejectors are placed in the lower part of the vessel or boat, one or more of such instruments being used as required. The throat or throats of the injectors or ejectors is or are securely fastened to the stern part of the skin of the vessel or boat, in which one or more openings are formed to correspond with the throat or throats of the injectors or ejectors. Steam is admitted through the instrument as in the injectors or ejectors at present in use, and water is drawn in through the suction pipe, which also has an opening through the side or skin of the vessel or boat, and the jet of water issuing from the apparatus at the stern acting against the water in which the vessel or boat floats, causes the propulsion of the ship, vessel, or boat forward.—Patent completed.

279 T. W. CARTER, Gray's Inn-road. *Propelling and steering.* Dated January 29, 1869.

The inventor proposes to form one or more longitudinal and transverse channels or water courses through the bottom portion of the ship or vessel. These channels form tubes running completely through the submerged portion of the ship or vessel, but being equally as watertight as the hull, make no difference, except in the space they occupy, with regard to the soundness of the general struc-

ture, unless it be to afford increased strength to the vessel. These channels may be of a circular, or square, or other section, as the case may require, not only on account of facility of construction, but of strength, and the suitability of any such particular form for the revolution of the propeller or paddle wheels, and for the position of the same and the rudders, either at the stem or stern of the vessel, or at both ends and within such channels or water courses. —Patent abandoned.

280 J. M'DONALD, Hackney. *Stoppers for bottles.* Dated January 29, 1869.

This consists in fitting in a socket formed with a screw thread, for screwing into a bottle or other vessel a hollow plug. This plug is closed at the bottom, but has a hole in the side near the bottom through which the fluid or air is free to pass. The upper portion of the plug is fitted with lugs to enable it to be turned, a pin or stud being on the outside to limit the movement, so as to ensure the openings corresponding. An aperture for the admission of air into the bottle is formed on the outside of the plug; this aperture coincides with a small hole in the socket, so that when the plug is turned and the vessel tilted, air enters through the aperture, and the fluid is free to run out.—Patent completed.

281 L. SMITH, Nottingham. *Taps.* Dated January 29, 1869.
